WHITE AND RED LEAD in 500-lb. lots sell as follows in cents per pound:

	Red				White	
	Feb. 28, 1918		1 Year Ago		Feb. 28, 1918	1 Yr. Ago
	Dry	In Oil	Dry	In Oil	Dry and In Oil	Dry and In Oil
25- and 50-lb. kegs	11.50	11.00	10.50	11.00	10.50	10.50
12½-lb. keg	11.75	11.25	10.75	11.25	10.75	10.75
100-lb. keg	11.25	11.50	11.00	11.50	11.00	11.00
1- to 5-lb. cans	13.25	13.00	12.50	12.50	13 00	12.50

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel 7/8 and smaller	30%	35%	40%*
Tinned	30%	35%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York ..... $7.00 Cleveland .... $5.85 Chicago $5.50

Coneheads same sizes:

New York ..... $7.10 Cleveland .... $5.95 Chicago $5 60

FIRE BRICK—Quotations on the different kinds in the cities named are as follows, f.o.b. works:

	New York	Chicago
Silica brick, per 1000	$50.00 to 55.00	$50.00
Fire clay brick, per 1000, No. 1	45.00 to 55.00	....
Magnesite brick, per net ton	135.00 to 145.00	....
Chrome brick, per net ton	135.00	....
Deadburned magnesite brick per net ton	85.00 to 90.00	....
Special furnace chrome brick per net ton	60.00 to 70.00	60.00 to 80.00

Standard size fire brick 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade $55 to $65. St. Louis grade, $40 to $50

Birmingham—Fire clay, $25 to $30; Denver, $23 per 1000.

Chicago—Second quality $25 per ton

FUEL OIL—Price variable, depending upon stock. New York quotations not available owing to this fact. In Chicago and St Louis the following prices are quoted:

	Chicago	St. Louis
Domestic light, 22-26 Baumé	5c.	None
Mexican heavy, 12-14 Baumé	7c.	7 1/16c.

Note—There is practically no fuel oil in Chicago at present time.

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Feb. 28 1918	One Year Ago
New York	$15.00	$8.00
Cleveland	15.30	7.50
Chicago	15.00	6.00

In coils an advance of 50c. usually is charged.

Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St. Louis	Denver
6 in. by 30 ft	$5.59	$4.94	$4.94	$4.32
7 in. by 30 ft	7.40	6.60	6.60	5.80
7 in. by 35 ft	10.70	9.60	9.60	8.55
8 in. by 35 ft	12.20	10.90	10.90	9.65
7 in. by 40 ft	12.35	11.00	11.00	9.75
8 in. by 40 ft	13.75	12.15	12.15	10.65
8 in. by 45 ft	18.20	16.20	16.20	14.30
8 in. by 50 ft	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads

For plain pine poles, delivered New York the price is as follows:

10-in butts, 5-in. tops, length 20-30 ft	$6.00
12-in. butts, 6-in. tops, length 30-40 ft	8 50
12-in. butts, 6-in. tops, length 41-50 ft	9.50
14-in. butts, 6-in. tops, length 51-60 ft	17 00
14-in butts, 6-in. tops, length 61 71 ft	18.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh, basing card in effect July 2, 1917, for iron, and May 1 for steel:

BUTT WELD

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized

7 to 8	38%	24½%	2½ to 4	29%	17%
9 to 12	33%	19½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts hold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	38%	42%	34.27%
3½ to 6 in. lap welded	18%	38%	21.27%
7 to 12 in. lap welded	10%	35%	21.27%

	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	22%	22%	19.27%
3½ to 6 in. lap welded	List	18%	13.27%
7 to 12 in. lap welded	List+20%	20%	6.27%

Malleable fittings, Class B and C, from New York stock sell at 5 and 5% from list prices. Cast iron, standard sizes, 34 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13 as agreed upon by manufacturers and the Government:

Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+ 5
2¼ in.	17½	2½ to 2¾ in.	+ 7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

	Per Net Ton		Per Net Ton
1 in.	$340	1¾ in.	$220
1¼ in	280	2 to 2¼ in	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

POWER

Vol. 47 NEW YORK, MARCH 12, 1918 No. 11

Help Yourself

By Rufus T. Strohm

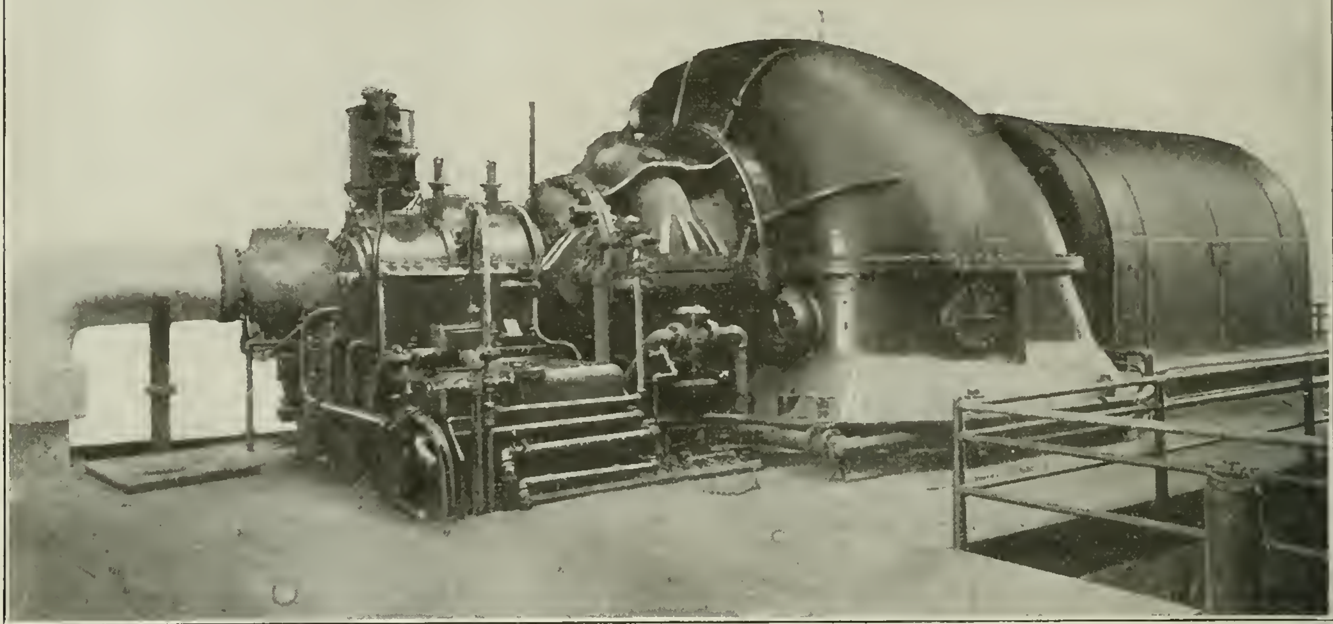
WE'RE apt to be filled with envy
At the mention of the chap
Whom circumstance, by a lucky chance,
Has tossed into Fortune's lap;
For the ordinary mortal
Is a poor and hapless elf,
And the best that he can expect to see
Is a way to help himself.

IT'S a comfort to the climber
Who would scale the mountain wall
To know a friend is at hand to lend
Swift help should he chance to fall;
But the man who scans most keenly
Each inch of the rocky shelf
Is the lonely wight on the dizzy height
Who is forced to help himself.

THE strides that the race is making
In its struggle toward the light
Have come by the throes and the sweat of those
Who have had to work and fight;
For earth doesn't owe its progress
To the Guildford or the Guelph,
But in shire and town to a Jones or Brown
Who has learned to help himself.

THE gawk who inherits millions
Has a cheap cause to be vain,
Since not one sou of the sum is due
To his use of brawn or brain;
But the engineer who labors
As he garners in the pelf
Has the cheering thought that his wealth is wrought
By the way he helps himself.

Ninety-Five Thousand Kilowatt



The Commonwealth Edison Co., of Chicago is completing the installation at Northwest Station of three additional turbo-generators of an aggregate capacity of 95,000 kw. Two are of the compound reaction type and the third an impulse machine of new design. One of each type is now in operation, and the second compound machine is in course of erection. At the turbine throttle steam is supplied at a pressure of 230 lb. gage and 200 deg. superheat.

WITH the present installation of three turbo-generators, two with a rating of 30,000 kw. and one of 35,000 kw., Northwest Station of the Commonwealth Edison Co., Chicago, Ill., will have an aggregate rated capacity of 165,000 kw. The plans calling for six units will have been completed, and the present building fully occupied.

As previously recorded in these columns, the station was first equipped with two 20,000-kw. vertical machines generating 25-cycle current. The next addition was unit No. 3, a horizontal compound turbine, with the double-flow low-pressure element in a separate casing, driving a 30,000-kw. 25-cycle generator. In service this machine has been found to have ample capacity for continuous operation at 35,000 kw. Full details of the unit are available in the June 20, 1916, issue of *Power*.

Of the three new units No. 4 (see headpiece above and Fig. 3) consists of an impulse turbine arranged in a single casing and a 25-cycle three-phase generator rated at 35,000 kw. at unity power factor. Units Nos. 5 and 6 consist each of a compound reaction turbine driving a 60-cycle three-phase generator (see headpiece on opposite page) rated to deliver 30,000 kw. at 85 per cent. power factor.

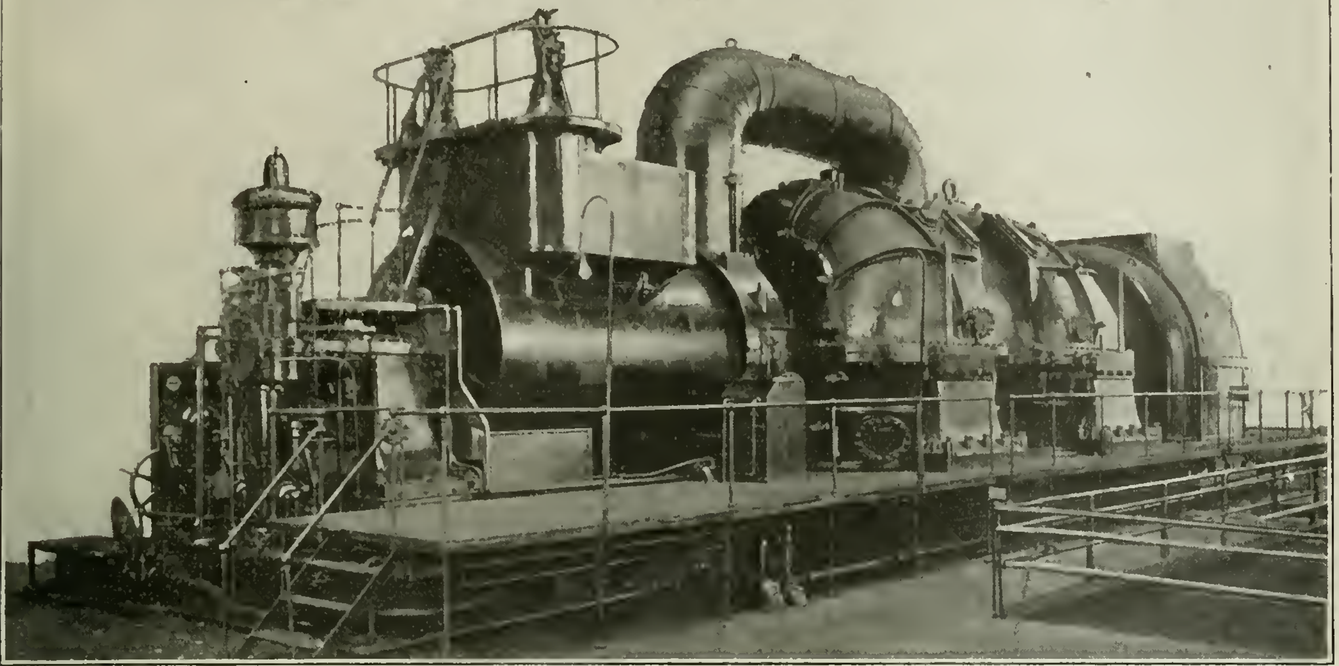
Unit No. 6 was the first of the new machines to be placed in service, and No. 5, now in the course of erection, will be a duplicate. The turbine is of tandem-compound design, the two rotating elements being connected by a solid flanged coupling. The generator is in turn connected through a flexible coupling so that all three rotors turn as one unit, in contradistinction to the cross-compound type, where each element of the turbine drives a separate generator. There are five main bearings, three on the turbine and two on the generator, with an additional small bearing on the outboard end of the direct-connected exciter. All bearings are served by the usual system of oil circulation. Normal oil temperature is maintained by an oil cooler supplied with water from the condenser circulating-water system. There are no cooling coils in the individual bearings.

The shaft packing consists of the well-known water gland with a steam labyrinth added, by means of which vacuum may be established before placing the turbine in operation. After sufficient speed is attained, the water gland is put in operation and the steam labyrinth shut off.

The high-pressure element of the turbine, which contains the governor and valve mechanism, is of standard single-flow pure reaction construction, containing a total of 90 rows of rotating and stationary blading. In this element the steam expands from the throttle pressure of 230 lb. gage down to a pressure of about 34 lb. absolute, at the most economical load. The steam passes next through an exhaust at the top of the cylinder into an overhead passage leading to the low-pressure element.

In the low-pressure element there is a combination of single- and double-flow construction, employing all-reaction blading. Steam from the high-pressure element enters at the top near the center and passes through a single-flow stage consisting of 20 stationary and

Addition to Northwest Station



rotating rows of blading, expanding from a pressure of 34 lb. absolute to approximately 8.5 lb. absolute. It is then divided, one half continuing through an adjacent low-pressure stage consisting of 16 rotating and stationary rows of blading, while the other half passes back around the single-flow stage, through passages between the inner and outer cylinders, to a duplicate pressure stage on the opposite end of the spindle. Each low-pressure stage has its separate exhaust passage to a condenser.

Steam admission is controlled by means of standard Westinghouse control mechanism, consisting of a governor controlling the main or primary steam-admission valve and two overload valves through an oil relay. The designed capacity on the primary valve is 25,000 kw., this being the point of maximum efficiency. The designed capacity on the secondary is 30,000 kw., and on the tertiary, 35,000 kilowatts.

The turbine is served by two condensers, shown to the right in Fig. 1, containing 28,000 sq.ft. each, or a total of 56,000 sq.ft. of cooling surface, in 12,972 tubes 1 in. in diameter and 16.5 ft. long between tube heads. The surface is disposed equally between the two shells, each taking steam from one of the low-pressure elements. On a basis of 30,000 kw. the condenser has 1.87 sq.ft. of surface per kilowatt.

At the entrance to each shell is a primary heater containing 750 sq.ft. of surface through which the condensate is passed, so that it may be heated to substantially the temperature of the exhaust steam. A bi-rotor circulating pump direct-connected to a 600-hp. induction motor (at the left in Fig. 1) furnishes cooling water to both sections of the condenser. This pump, when running at a speed of 350 r.p.m., has capacity to deliver 60,000 gal. of water per minute against a head of 18 feet.

Each shell of the condenser is served by a condensate pump and a hydraulic air pump of the Leblanc type, Fig. 2. Both pumps are turbine-driven on a common shaft. Each of these auxiliary sets is of sufficient size to serve the main unit when operating at its maximum capacity, thus giving one set for reserve. The condensate is pumped through the condenser preheater and to the feed-water heater. From the heater the feed water passes through the boiler-feed pumps and thence through the economizers to the five boilers of the unit.

The makeup water, which serves to supply any deficiency in the boiler feed, is drawn from a fresh-water reservoir in which is collected the heater overflow, trap discharges and condensation that would otherwise be wasted. At such times as the supply of condensation to the fresh-water reservoir is insufficient, filtered water is admitted through a float valve. The makeup water is drawn from this reservoir into the condenser by the vacuum, the amount being regulated by a float valve on the feed-water heater.

The generator of unit No. 6 (see headpiece on this page) is of standard construction, star-connected, being designed to deliver three-phase 60-cycle current at 12,000 volts. The speed is 1200 r.p.m. and the rating 35,300 kv.-a., or 30,000 kw. at 85 per cent. power factor.

For cooling the generator windings, a motor-driven blower has been installed with capacity to deliver 120,000 cu.ft. of air per minute. The air-intake passage is equipped with an air washer of suitable capacity, which comprises the usual complement of spray chamber, eliminators and tempering coils to clean, cool and humidify the air. Sufficient steam at low pressure is supplied to the tempering coils to maintain the humidity at the desired point below saturation. The motors driving the blower, circulating pump and economizer fans operate on 440-volt service and have standard remote-control starting equipment. The motors are brought up to speed automatically by a system of accelerating relays and air-break contactor-type circuit-breakers with push-button control.

Unit No. 4 (see headpiece on page 354 and Fig. 3), the second of the new machines to be placed in service, is of a relatively new type of which a striking feature is the compactness of arrangement for a unit of such large capacity. The turbine is of the impulse type. The wheels, arranged in a single casing, increase progressively in diameter from the first to the last stage. Similarly, there is an increase in the length of the blading conforming in a general way to the increase in volume of the steam in its expansion as it passes through the turbine.

Steam is admitted to the annular ring supplying the first-stage nozzles through a single-balanced valve closed by a spring and opened by a cam-actuated lever under the control of the governor. A secondary control valve of similar design supplies steam to one of the intermediate stages of the machine, this valve opening automatically when the load on the unit reaches a certain predetermined capacity. By the new arrangement the numerous admission valves of former designs have been eliminated.

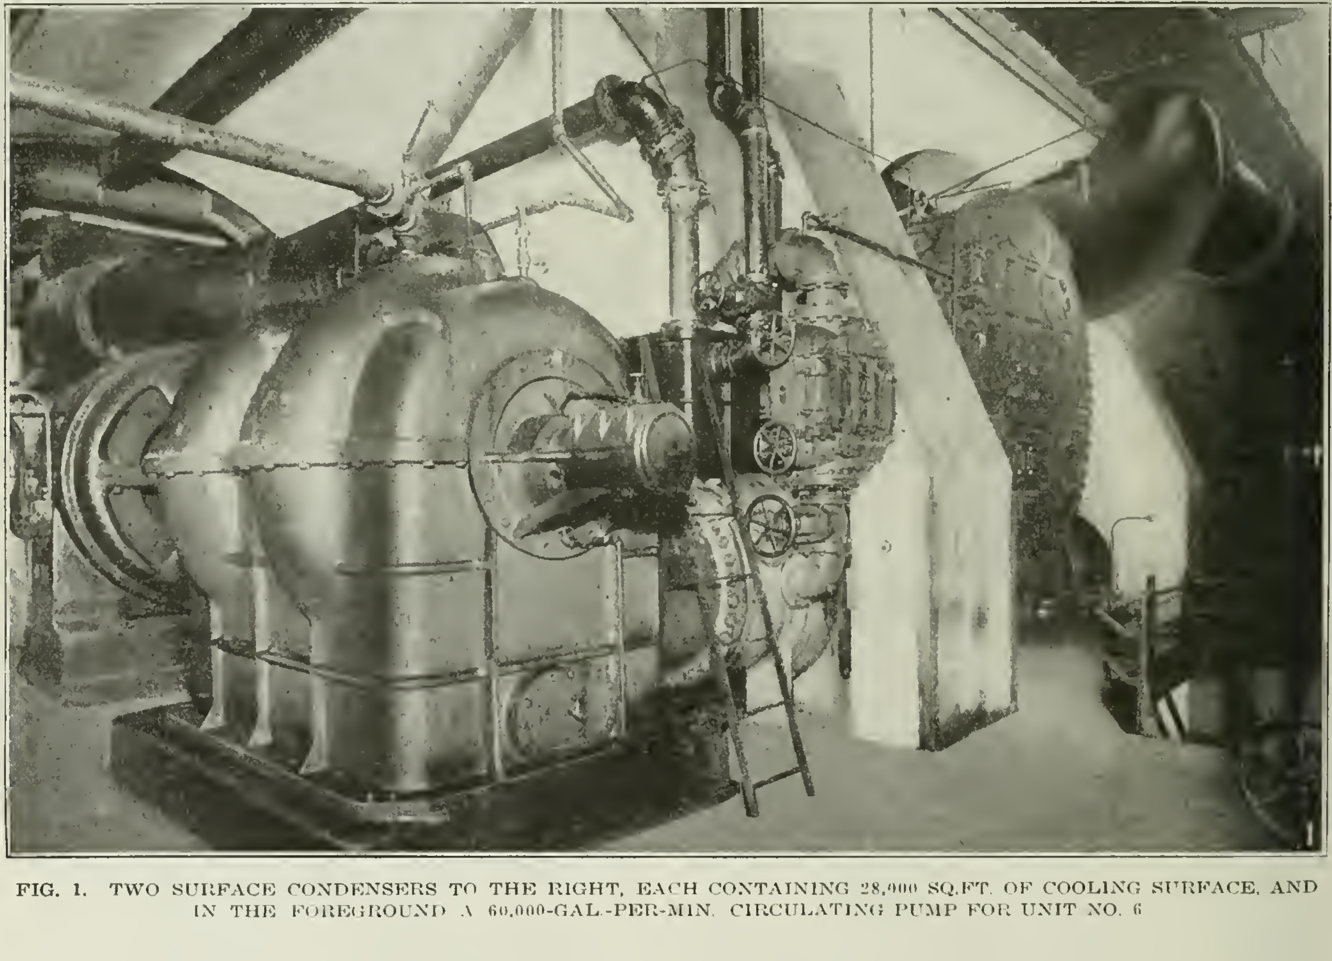


FIG. 1. TWO SURFACE CONDENSERS TO THE RIGHT, EACH CONTAINING 28,000 SQ.FT. OF COOLING SURFACE, AND IN THE FOREGROUND A 60,000-GAL.-PER-MIN. CIRCULATING PUMP FOR UNIT NO. 6

The unit has four main bearings cooled by water from the house service. Bearing oil is supplied under forced circulation at about 20 lb. pressure, by a screw pump geared to the turbine shaft. In starting, use is made of an auxiliary steam pump that is cut out of service when the unit is up to speed.

The turbine of unit No. 4 is served by a two-pass surface condenser, Fig. 4, containing 56,000 sq.ft. of surface. The condenser is rigidly connected to the turbine exhaust, the necessary freedom for expansion being provided by supporting the condenser on springs. Cooling water is circulated by a bi-rotor 48-in. centrifugal pump, Fig. 5, driven by a 600-hp. induction motor. The speed is 300 r.p.m. and the capacity against an 18-ft. head, 60,000 gal. per min. There are two sets of combined air and condensate pumps, Fig. 6, each set being driven by a 190-hp. turbine running 1500 r.p.m. One set is a stand-by to the other.

The general arrangement of the auxiliaries is somewhat similar to those for unit No. 6. With the combination pump, both air and condensate are withdrawn from the condenser, separate piping connections being provided. The air is discharged with the hurling water to a reservoir from which it escapes into the room, and the condensate is passed through the preheater at the top of the condenser to the feed-water heater. Cross-connections allow either pump to serve the condenser. As the hurling water is constantly recirculated, it requires cooling. For this purpose a surface-type cooler is inserted in the hurling-water reservoir and a certain percentage of the condenser circulating water is passed through the tubes. Arrangements for the supply of makeup water to the condenser are as previously described for unit No. 6.

The electrical generator of unit No. 4 is a three-phase 25-cycle machine rated to deliver 35,000 kw. at unity power factor, the speed being 1500 r.p.m. A 250-volt 110-kw. shunt-wound exciter is mounted at the end of the generator shaft. Cooling air for the main generator is washed, cooled and humidified as in the case of the other unit, but the air is forced through the machine by the action of the generator rotor, no independent blower being used. The heated air from the generators is discharged to the boiler-room basement, whence it finds its way to the boiler furnaces. This saving of heat that otherwise would be wasted is in line with modern tendencies.

In general the new boiler installations are similar to the equipment installed for unit No. 3, which, as previously mentioned, was described in the June 20, 1916, issue of *Power*. May 16 and 30, 1916, issues dealt with the condenser-circulating and the coal-handling system.

As a brief summary it may be stated that the steam-generating equipment for each of the new units consists of five cross-drum water-tube boilers generating steam at 240 lb. gage and 200 deg. F. superheat. Each boiler contains 12,200 sq.ft. of steam-making surface, giving 61,000 sq.ft. for the unit. Two chain grates having a total active area of 304 sq.ft., bearing a ratio to the steam-making surface of 1 to 40, are placed under each boiler. The furnace is of the expanding type with a tile roof and the first pass at the rear. Each boiler is connected to an economizer containing 6450 sq.ft. of tube surface and equipped with a motor-driven induced-draft fan capable of handling 90,000 cu.ft. of hot gases per minute. Five boilers are served by a self-supporting steel stack 18 ft. in diameter and 250 ft. in height above the boiler-room floor, the base of the stack resting on a steel structure at a level 66 ft. above the boiler-room floor. Two turbine-driven boiler-feed pumps are installed for each unit, the capacity of each pump being 900 gal. per minute.

The electrical system follows the standard practice of the company of simple two-bus arrangement. The alternators are star-connected with the neutral end of each phase brought outside of the machine for the purpose of connecting in current transformers used in connection with protective relays. Beyond the current transformers the three leads are brought together to form the neutral point of the star, from which connection to the neutral bus is made through an oil switch.

For each unit the stator leads consist of two cables per phase. In the case of unit No. 4 each cable has 1,500,000 cir.mils cross-section, and the cables of No. 6, the 60-cycle generator, have 1,250,000 cir.mils. cross-section each. The leads are lead-covered and are carried within barrier structures similar to the busbar construction. The lead sheath is grounded solidly at the generator end and through a resistance of about ten ohms at the other end.

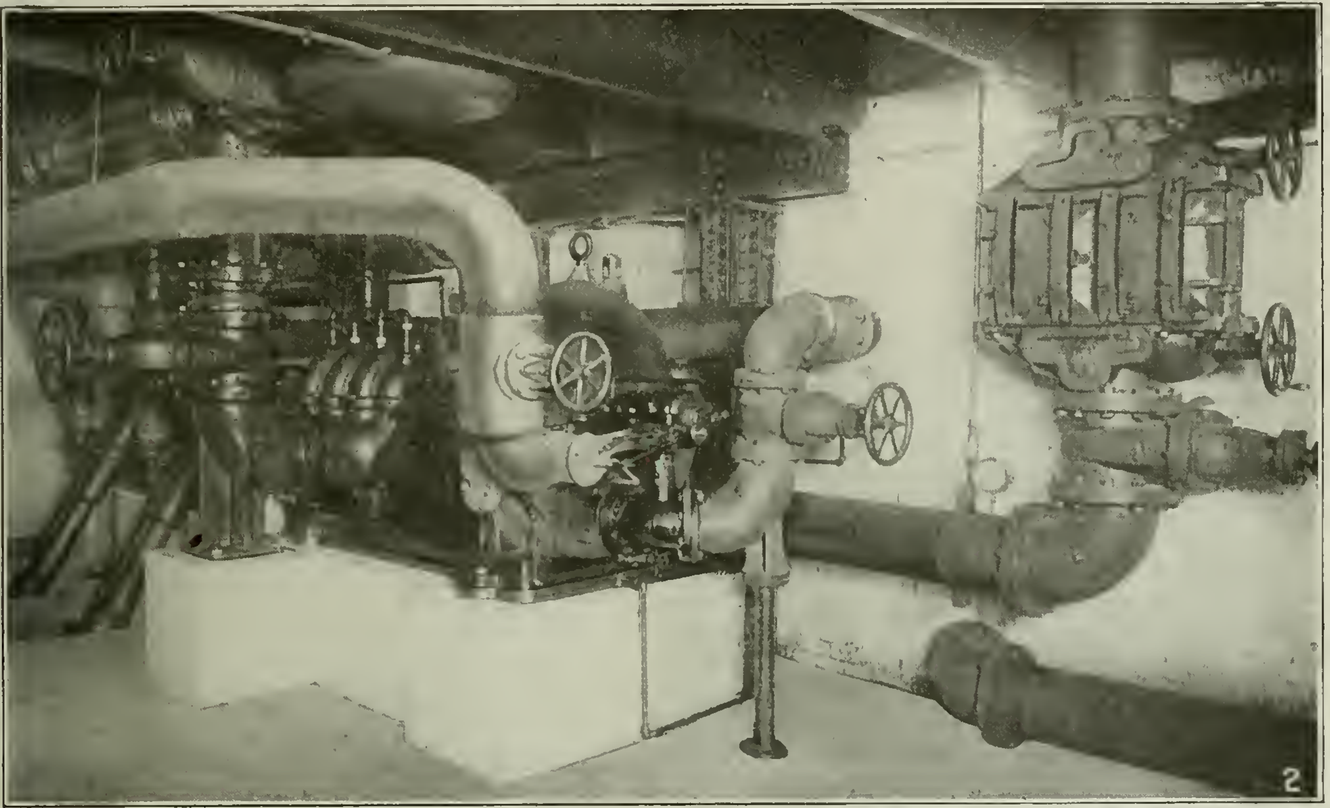

FIG. 2. TURBINE-DRIVEN CONDENSATE AND HYDRAULIC AIR PUMP FOR UNIT NO. 6

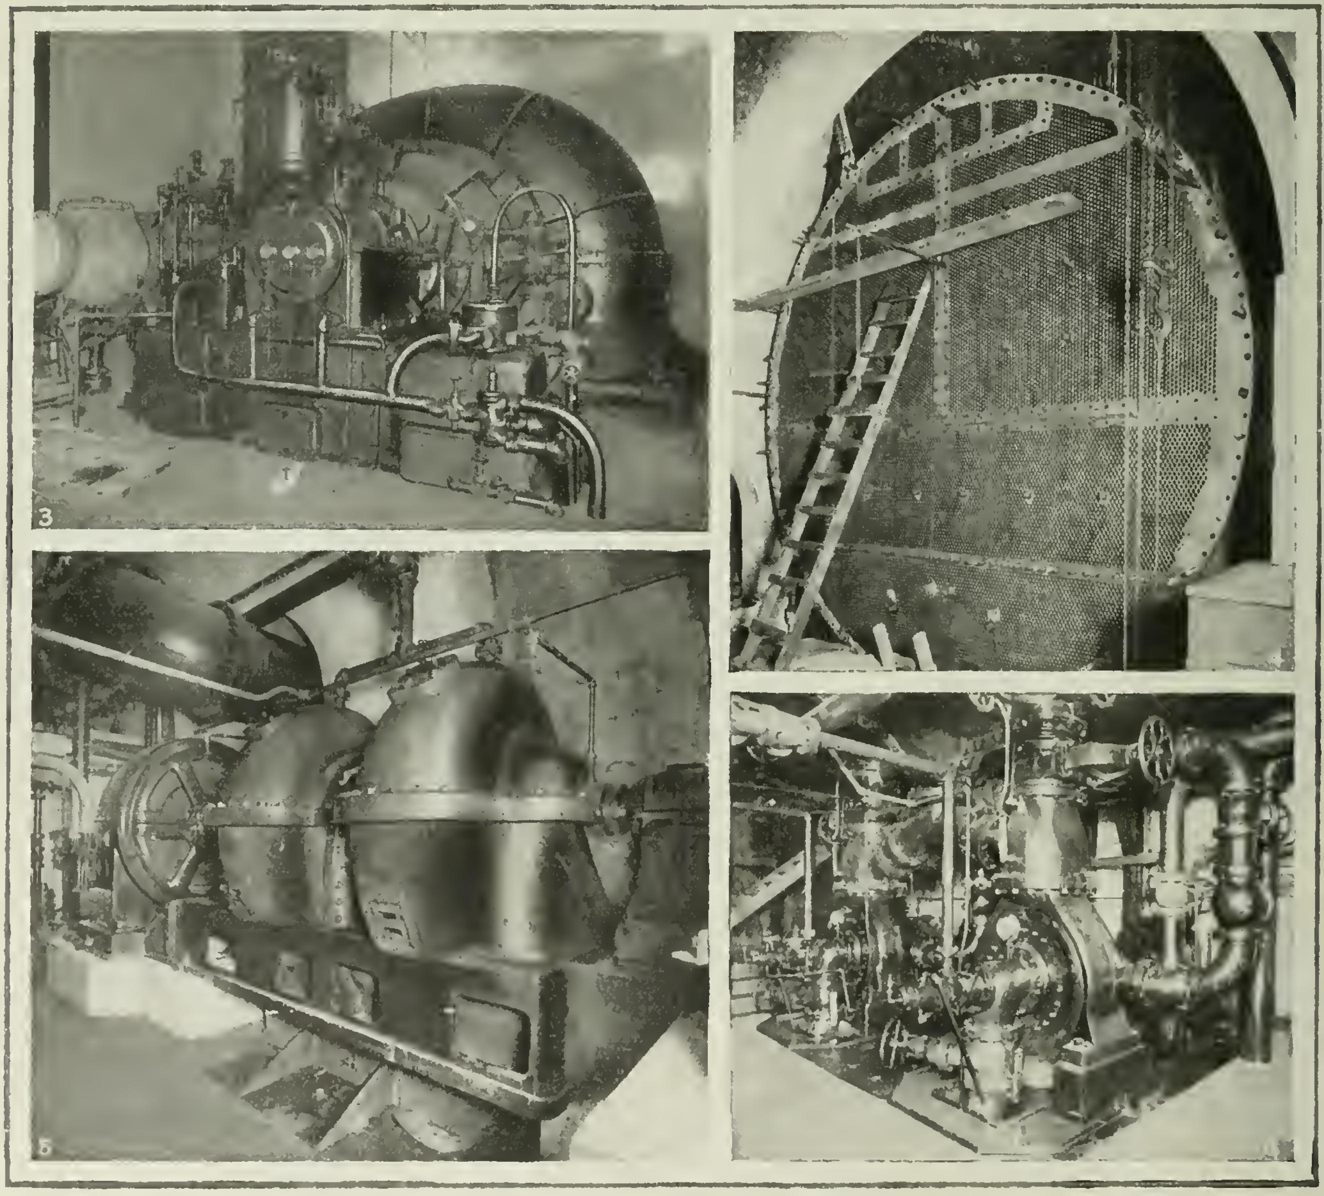
On each unit is used the company's standard system of protection for the generator. It consists of balanced relays that balance the current going through the neutral end of each phase winding against the current flowing in that same phase lead at the oil-switch end of the connection. In case of a fault in the generator windings or leads between the windings and the oil switches, which include in the 25-cycle units the generator reactor coils, these relays operate and instantly open the main oil switch, the neutral oil switch if it is closed, the field switch, and in the case of the 60-cycle machine, the switch on the motor driving the generator's ventilating blower. The opening circuit of the field switch is connected in series with contacts on the main oil-switch mechanism so as to insure against the opening of the field before the alternator's stator circuit has been opened.

For the preceding information on steam equipment, *Power* is indebted to Sargent & Lundy, consulting engineers for the Commonwealth Edison Co. The electrical data came from the electrical department of the company.

PRINCIPAL DATA ON EQUIPMENT OF NEW UNITS

Turbo-Generator No. 4	
Turbine	General Electric single-cylinder horizontal impulse type
Capacity, kw	35,000
Speed, r.p.m	1,500
Generator	Three-phase, 25-cycle, 9,000 volts
Capacity, unity power factor, kw	35,000
Exciter, direct-connected, capacity, kw	95
Air for cooling, cu.ft per min	60,000
Unit:	
Length, over-all, ft	50
Width, ft.-in	19–10
Floor space per kw. (35,000 kw.), sq.ft	0.028
Condenser	Two-pass surface, Wheeler Condenser and Engineering Co.
Number of tubes, including preheater	12,959
Tube diameter, o. d., in	1
Length between heads, ft	16.5
Surface, sq.ft	56,000
Surface per kw. (35,000 kw.)	1.6
Circulating pump	Wheeler bi-rotor
Capacity, 18-ft. head, gal. per min	60,000
Driven by G E., 440-volt 3-phase 600-hp. induction motor, speed, r.p.m.	300
Combined air and condensate pumps, two units	Wheeler
Each unit driven by 190-hp. G. E. turbine, r.p.m	1,500
Capacity condensate pump, gal. per min	1,200
Turbo-Generator No 6	
Turbine	Westinghouse two-cylinder reaction
Capacity, kw	30,000
Rows of blading, h.-p. element	90
Rows of blading, l.-p. element, single-flow	20
Rows of blading, l.-p. element, 2 double-flow stages, each	16
Speed, r.p.m	1,200
Generator	Three-phase, 60-cycle, 12,000 volts
Capacity, 85 per cent. p.f., kw.	30,000
Exciter, direct-connected, shunt-wound, capacity, kw	110
Cooling air, cu.ft. per min	120,000
Unit:	
Length over-all, ft.-in	72-9
Width, ft.-in	19-2
Floor space per kw. (30,000 kw.) sq.ft	0.046
Condenser	Westinghouse surface, two shells
Number of tubes	12,972
Tube diameter, o.d., in	1
Length between heads, ft	16.5
Surface, including preheater, sq.ft	56,000
Surface per kw. (30,000 kw.), sq.ft	1.87
Circulating pump	Westinghouse bi-rotor
Capacity, 18-ft. head, gal. per min	60,000
Driven by Westinghouse 600-hp., 440-volt ind motor, speed, r.p.m.	350
Air pump	Leblanc, same shaft as condensate pump, two units, each driven by 139-h.p. Westinghouse turbine
Capacity condensate pump, gal. per min	1,200
Boiler Unit for No. 4 or No. 6	
Boilers	B. & W Cross-Drum
Number of boilers to each turbine	5
Tubes per boiler	588
Diameter of tubes, in	4
Length of tubes, ft	18
Steam-making surface per boiler, sq.ft	12,200
Pressure at turbine throttle, lb. gage	230
Superheat at turbine throttle, deg. F	200
Temperature of steam at throttle, deg. F	600
Nominal capacity each boiler, lb. steam per hour	85,000
Size steam main to turbine, outside diameter, in	20
Stoker, two per boiler	B. & W Chain Grate
Active area two stokers, sq.ft	304.6
Ratio grate area to steam-making surface	1 to 40
Pumps, two boiler-feed per unit	Worthington, turbine-driven three-stage
Capacity, lb. per hour	450,000
Feed-water heater	Open type, Warren Webster
Capacity from 60-150 deg. F., lb. per hour	400,000
Economizer, one per boiler	B F Sturtevant
Number of tubes	456
Length of tubes, ft.	12
Heating surface in tubes, sq.ft	6,450
Fans, induced-draft	B F Sturtevant multivane
Capacity, cu.ft. hot gases per min	90,000
Stack	Steel self-supporting
Height above boiler-room floor, ft	250
Diameter inside, ft	18



FIGS. 3 TO 6. TURBINE AND CONDENSER EQUIPMENT OF UNIT NO. 4

The Selection of Ammonia Condensers

By M. A. SALLER

Some suggestions are made to assist the engineer in getting acquainted with the chief factors that should guide him in the selection of condensers for the refrigerating plant.

IN THE following it is not the intention of the writer to go into a thorough analysis of the advantages and disadvantages of the various types of condensers for refrigeration plants, but merely to suggest the chief points with which the engineer should acquaint himself before selecting a particular type.

Condensers for use in compression or absorption plants are made in four general types: Atmospheric, or open-air type; double-pipe, or closed condensers; straight-tube surface condensers; submerged condensers.

In the atmospheric, or open-air condenser, a number of coils or passes are employed through which the ammonia gas flows, the cold cooling water trickling down over the outside of the pipes from a trough or distributor above, to a collecting pan or basin below.

The double-pipe condenser, as the name implies, consists of a double set of pipes, one located inside the other, the ammonia passing through the inner tube, while the cooling water is passed through the coil surrounding it.

The straight-tube surface condenser is designed along the same lines as the surface condenser regularly used in steam-engine and turbine practice.

The submerged condenser consists of ammonia-carrying coils submerged in a tank through which the cooling water is circulated.

SELECTION OF TYPE RESTS LARGELY ON CONDITIONS

The decision as to which of the four types should be used rests largely on the conditions surrounding the plant, its method of operation and the amount of money available. That the operator may have suggested to him all the various factors, the different points for and against each type are briefly outlined. Present-day practice in refrigerating-plant service tends toward the use of the atmospheric and double-pipe types in the great majority of cases, the outstanding feature of the atmospheric type being its simplicity and low first cost, while the double-pipe condenser is often preferred because of its high efficiency.

One of the worst features of the double-pipe condenser is that if a water containing an appreciable quantity of foreign matter or scale-forming impurities is used for cooling purposes, it will quickly collect in the pipe and cause a coating of the surfaces which will greatly reduce the efficiency and finally cause complete stoppage of the pipe. It should be remembered that scale in a double-pipe condenser is a more serious matter than in the atmospheric type. With the exposed surface of the atmospheric condenser any deposit which forms will be quickly noticed and may be readily scraped off even while the condenser is in operation, while in the double-pipe condenser the coating of scale can be detected only by shutting down the plant for examination or by noting a reduction in the efficiency of the plant, following which the unit must be cut out of service for cleaning.

A scale formation of the same thickness is also a more serious matter in the double-pipe condenser than in the atmospheric type. In the latter case the scale gathers on the outer surface of the tubes and really might be said to increase the area of the cooling surface, though probably not sufficiently to counterbalance the insulating properties of the scale.

Scale in the double-pipe condenser forms on the outer surface of the inner pipe and materially decreases the heat-transmission efficiency; also, it forms on the inner surface of the outer pipe and reduces the sectional area of the water passage.

OTHER DISADVANTAGES OF DOUBLE-PIPE CONDENSER

The decrease in the transverse area of the water-carrying tubes caused by scale in a double-pipe condenser also requires an increase in power to circulate the water through it, and in the same proportion the flow of water decreases if extra pressure is not applied. In the atmospheric condenser, where the cooling water merely flows over the coils by gravity, the quantity or distribution of the water is not affected by scale formation. As in cooling-tower practice, advantage is taken in the atmospheric condenser of the reduction in temperature resulting from the evaporation of some of the water which is cooled by the natural air currents and the outside temperature prevailing. This slight advantage is lost with the double-pipe condenser.

It should also be considered that the matter of ammonia leaks in the double-pipe condenser operates to its disadvantage. Because of the great affinity of anhydrous ammonia for water, a leak in a double-pipe condenser may continue for a long time, the ammonia being absorbed by the circulating water, without detection. The double-pipe condenser requires extra attention when shutting down the plant, especially in winter. Should the water remaining in the closed circuit of the double-pipe condenser be frozen, the rupture of one or more of the pipes or fittings is likely to occur.

In first cost the atmospheric condenser has an advantage over the double-pipe condenser because only a single coil of pipe, with much simpler connections, is required with a distributing and collecting trough, as compared to the double set of coils and special fittings usually found in the double pipe. As a general rule it can be figured that the first cost of the double-pipe condenser runs from three to four times the cost of the atmospheric type, figured on the basis of square feet of cooling surface.

In the matter of compactness, however, the double-pipe condenser has the advantage because, due to its higher efficiency, a small condenser will do the same work as a larger atmospheric condenser. The double-pipe condenser can also be installed indoors, while the atmospheric type must be installed outdoors or in a room separated from other machinery because of the presence of moisture. By reason of its compactness and freedom from moisture and water splashing, the double-pipe condenser can be located close to the ice machine, with a saving in cost of pipe lines, therefore this type is frequently used in small plants.

Where the cooling water is to be used over again for other purposes under pressure, the double-pipe condenser also possesses an advantage, in that the cooling water can be taken from the condenser under pressure to any other point of use, whereas in the atmospheric type all the pressure is dissipated when the water is exposed to the atmosphere. Where an unlimited supply of cheap water under pressure is available, the double-tube condenser can also be used to advantage and can frequently be installed in the lower portion of the building, saving the investment in an extra set of pumps which might be required to force the water up to an atmospheric condenser installed up high on the roof. In congested localities, such as in the heart of cities, the water and moisture passed out to the atmosphere by the open type of condenser is often objectionable, and in these cases the double type offers a nice solution of the problem.

HIGH EFFICIENCY OF DOUBLE-TUBE TYPE

Given favorable operating conditions—good clean cooling water, clean pipes and high velocity of circulating water—a high efficiency can be secured from the double-tube condenser. Giving the double-tube condenser the benefit of these favorable conditions, the comparison of the two types expressed in number of B.t.u. exchanged per square foot of cooling surface per hour can be stated as: Atmospheric type, 60 B.t.u. per deg. difference; double-tube type, 100 B.t.u. per deg. difference.

Because of this theoretically higher efficiency it should be possible to do the work with the double-tube condenser with 40 per cent. less cooling surface than in an atmospheric condenser; but when it is considered that the cooling surface in the double-tube type costs about 300 per cent. more than the atmospheric, this apparent advantage must be qualified. It should also be remembered that this theoretical efficiency will not always be encountered because of the unfavorableness of operating conditions.

Summed up, it would appear that the atmospheric condenser is the type that can be used to advantage in the average plant where no restrictions are encountered as to roof space, building congestion, etc., though the double type appears to be the most attractive where good cooling water is available or where the condenser can advantageously be located inside the building or near the compressor.

As to the straight-tube surface condenser, this is not so generally used on account of the expensive construction involved as against the atmospheric type, because it is subject to the same troubles from "scaly" water as the double-tube type, and because trouble is usually experienced in maintaining tight connections at the tube heads, the ammonia leakage being quite considerable unless constant attention is paid to keeping the tubes tight.

The submerged type of condenser is very cheap, comprising merely a tank and some ammonia coils, though it is not desirable for large-plant work because of the large size of tank required and the weight of the large volume of water it carries. The matter of detecting leakage is also unfavorable. In a condenser of this type it is also often necessary to install stirring apparatus to insure proper circulation.

Fyrox Moving West

The present condition of stress makes the public more susceptible to the exploitation of nostrums that are supposed to save a large percentage of coal. Purveyors of these preparations are alive to the situation. Our old friend "Fyrox," so active in the East last summer, and of which *Power* had something to say on page 56 of the July 10, 1917, issue, recently bobbed up in Detroit. As may be remembered, the compound is in powder form put up in one-pound boxes which sell for one dollar. A box of the compound is dissolved in 8 to 10 gal. of water, depending upon the size of coal burned, and the resulting solution is sprinkled over the coal. According to the directions given this amount is sufficient to treat two tons of coal. It is claimed that ordinarily two tons of treated coal will last as long as three tons of the untreated, thus saving one-third of the coal bill.

An inquisitive citizen of Detroit brought a box of the preparation to J. C. McCabe, director of the Department of Safety Engineering, requesting an opinion on its merits. An analysis by the Detroit Testing Laboratory showed the following ingredients:

	Per Cent.
Moisture	0.51
Common salt with trace of potassium chloride	89 93
Potassium permanganate	0 23
Potassium chlorate	0 88
Carbon	2.45
Sugar	6 00
	100 00

In other words, nearly nine-tenths of the preparation is common salt, and the cost of one pound of the mixture at the present high prices is about six cents. Apparently, if there were any advantage in using such a compound, it would be considerably cheaper to patronize the local stores.

When sprinkled on a hot fire salt produces a highly colored flame, but does not add to the heat value of the fuel. If used in sufficient quantity, it would tend to slow up combustion and eventually extinguish the fire. Less coal would be burned and less heat would be generated.

It will be noticed that one pound of Fyrox is used to 4000 lb. of coal, the proportion being 0.025 per cent. It should be evident that any benefit, or for that matter injury, to combustion must be negligible.

Calorimetric tests on two identical samples of coal, one without and the other with 400 times the amount of Fyrox specified, gave 11,517 and 11,767 B.t.u. respectively. The second test was made with a slightly heavier fusion wire, which would mean a little more heat in the calorimeter. The usual variation between readings is about 2 per cent., or in the present case, say, 200 B.t.u., so that for all practical purposes the heat from each sample of coal was identical.

If it is the psychological effect that is desired, something that will influence the fireman to improve his methods and to watch the fire more carefully than usual, why not use plain water and give it a trade name to conceal its identity? The results would be equivalent and the cost much less.

The Electrical Study Course—Commutation

The process involved in the armature coils under commutation is explained, and one of the methods that may be used to assist in commutating the current is pointed out.

IN FIG. 1 the lines of force pass from the N pole into the armature core between points *B* and *D*; likewise under the S pole the magnetic flux passes from the armature core into the S pole between points *A* and *C*. It is only between these points that the armature conductors will be cutting the lines of force and therefore generating voltage, when the armature is revolved. Between points *A* and *B* on the left-hand side of the armature and *C* and *D* on the right-hand side, the conductors are outside of the magnetic field and are not cutting the latter; therefore do not produce any voltage. The space between the polepieces where the conductors do not cut any line of force is called the neutral point or neutral zone. It is always at this point that the brushes must be located on the commutator, because if they are very far off the neutral, serious sparking will result.

In general it is possible to shift the brushes slightly ahead of the neutral, that is, in the direction that the armature is turning, or to shift them slightly back of the neutral, against the direction of rotation, without seriously interfering with the operation of the machine. In some cases the brushes can be shifted slightly ahead or back of the neutral with beneficial effect upon the operation of the machine. However, this is a subject to be considered in a later lesson.

We have already seen in a previous lesson how a ring divided into two parts acts to cause an alternating current generated in a coil revolving between the poles of a magnet to flow in one direction in the external circuit. It will be recalled that, although the current was caused to flow in one direction, the current was of a pulsating nature; that is, flowed in waves. Where a number of coils are connected to a commutator, as in Fig. 1, the current not only flows in one direction in the external circuit, but also is maintained at a constant value. This will be seen by considering what takes place at the brushes as the armature revolves.

In Fig. 2 the armature is shown after it has been revolved one segment from the position shown in Fig. 1. In Fig. 2 coil *k*, which was under the N pole in Fig. 1, has moved out from under the pole and into the neutral zone, while coil *j*, which is in the neutral zone in Fig. 1, has moved in under the N pole, thus maintaining the same number of active conductors under this pole. The same thing has happened under the S pole, where coil *g*, which is under this pole in Fig. 1, has moved out into the neutral zone and coil *h* has come in under the pole, thus maintaining the number of active conductors under this pole constant and consequently maintaining the voltage at the brushes constant, which in turn will cause a current of constant value to flow in an external circuit *L* of constant resistance. This is the process that is going on all the time in the armature as long as it is revolved. As fast as one armature coil moves out from under a polepiece, another moves in to take its place, thus maintaining the number of active coils on the armature constant.

The process that takes place around the coils under commutation, that is, the coils in the neutral zone, is one of the most complicated operations in the machine. In Fig. 1 the current in coil *l* is flowing up through the plane of the paper and to the positive brush. At the negative brush the current is flowing from segment *c* to coil *m* and down through the plane of the paper. In Fig. 2 the current in coil *l* is flowing down through the plane of the paper and to segment *e* and then to the positive brush, and at the negative brush the current is flowing in through segment *b* and to coil *m*, up through the plane of the paper. From this it is seen that the direction of the current in coils *l* and *m* is reversed in Fig. 2 from that of Fig. 1. In other words, when the armature revolves through an arc equal to the width of a commutator segment, that is, causes one segment to move out from under a brush and another to move in, the current in a coil connected to the segments that the brushes rests on is reversed.

In changing from the condition in Fig. 1 to that in Fig. 2, there was a period when coils *l* and *m* were short-circuited; this is shown in Fig. 3. In this case the positive brush rests on segments *d* and *e* and the negative brush on segments *b* and *c*. When the brushes are in this position, as far as the circuits in the armature are concerned there need not be any current flowing in coils *l* and *m*, since as shown in the figure, the current to the positive brush can flow directly from coils *h* and *k* without flowing through coil *l*. Likewise at the negative brush, the current is from the brush to coils *g* and *j* without passing through coil *m*. In other words, coils *m* and *l* are shunted out of circuit, until the brushes move onto segments *b* and *e*, as in Fig. 2, where the current must flow in an opposite direction, in coils *l* and *m*, to that in Fig. 1.

The foregoing might be easily accomplished if it were not for the property of self-induction, which is present in every electrical circuit when the current is changing in value. It was shown in the lesson in the Dec. 4 issue, that when the current is increasing in value in a conductor, the conductors cut the line of force set up by the current and induce a voltage that tends to prevent the current from increasing in value, and when the current is decreasing in value, the conductors cut the line of force in a direction which creates a voltage that tends to keep the current flowing in the circuit. In other words, the effect of induction is to oppose any change in the value of the current in the circuit.

Let us see what the result of self-induction is upon the armature coils under commutation, such as coils *l* and *m* in the figures. Start with Fig. 1 and consider only the positive brush. The brush moves off segment *d* onto segment *e* bridging across the insulation between the two segments, as in Fig. 3. If it were not for the induction of the coil, there would be no reason for the current flowing in coil *l*, Fig. 3, but when the coil is short-circuited and the current starts to decrease, it is prevented from doing so by induction and for a short period must continue to flow through the coil into segment *d*. If this continues until segment *d* moves out from under the brush and segment *e* moves in, as in Fig. 2, then the current must not only cease flowing from coil *l* to segment *d*, but also reverse its direction and build up to full value in the opposite direction, as in Fig. 2. In the latter case induction again tends to prevent the current from building up in the opposite direction. The result of this is, if some means, which will be considered later, is not employed to make the current spark is produced in a make-and-break ignition system on a gas engine. Another thing is that as segment *d* moves out from under the brush, the contact between the brush is getting smaller all the time until the brush leaves the segment. If considerable current is kept flowing from the coil under commutation into the segment that the brush is leaving, such as coil *l* to segment *d*, Fig. 3, it may increase the temperature of the trailing corner of the brush to the point where it will glow.

FIG. 3

FIG. 4

FIGS. 1 TO 4. DIAGRAMMATICAL REPRESENTATION OF A DIRECT-CURRENT GENERATOR

reverse in the coil under commutation in the time required for the brush to pass from one segment to another, severe sparking at the brushes will take place. This is caused by the current not being able to reverse in the coil, in the time that the brush passes from one segment to another, and follows the brush across the insulation between the segments, similar to the way the

The time during which the current must decrease from full value to zero and build up to full value in the opposite direction is very small. For example, assume that the armature in the figure is revolving at 1500 r.p.m., which is not an excessive speed. Since there are 24 segments in the commutator, 24 × 1500 = 36,000 segments pass each brush per minute, or 600 segments per second. We have just seen that each time a segment passes a brush, the current reverses in a coil. Therefore, when a two-pole armature having 24 segments revolves at 1500 r.p.m., the current must reverse in the coil under commutation in $\frac{1}{600}$ part of a second. From this it is evident that it may be a somewhat difficult proposition to make the current properly reverse in the coil in such a short period.

At the positive brush the current is flowing up through the coil under commutation and must be reversed and caused to flow down, each time that a segment moves out from under the brush and another one moves in. What would help to reverse the current would be an electromotive force induced in the coil opposite to the direction that the current is flowing in the coil under commutation; that is, if the current is up through the plane of the paper, the voltage will have to be downward to assist in changing the direction of the current. In the figure all the conductors under the S pole have an electromotive force induced in them down through the plane of the paper. Therefore, if the brushes are shifted so that the positive brush will come under the tip of the S pole, as in Fig. 4, the coil under commutation will have a voltage induced in it that is opposite to the flow of the current in the coil. When the brushes are properly located, they will be in a position where the voltage generated in the coil will be just sufficient to reverse the current during the period of commutation.

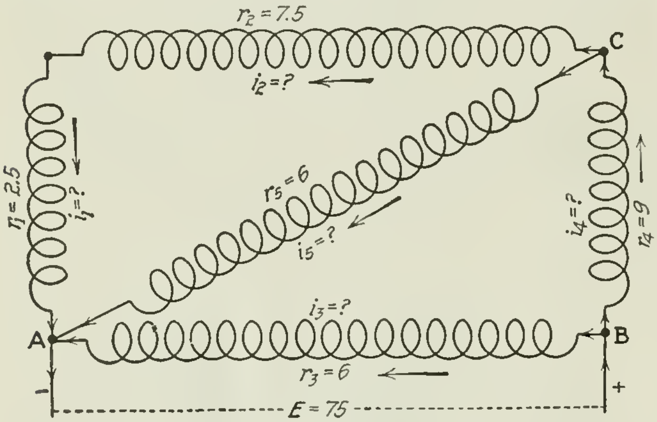

FIG. 5. COMPLEX CIRCUIT

The foregoing is one way to obtain sparkless commutation and was the one usually relied upon in the early type of machines, but by improvement in design it has become possible to build generators and motors that will operate over their entire range from no load to full load with the brushes located exactly between the pole-pieces without sparking. Further consideration will be given this subject in later lessons. It will be noted that the brushes are shifted in the direction in which the armature is revolving. However, this is true only of a generator.

When we consider the electric motor, it will be found that the brushes must be shifted against the direction of rotation, to assist in reversing the current in the coil under commutation.

In Fig. 5 is given the layout of the problem given in the last lesson, and it is worked out in a manner similar to the one solved in that lesson. Here we have two circuits, a simple one from B through $r_3 = 6$ ohms to A, and a second, a complex circuit, from B through $r_4 = 9$ ohms to C; at this point the circuit divides, one part going through $r_5 = 6$ ohms and the other through $r_2 = 7.5$ ohms in series with $r_1 = 2.5$ ohms to A. It is evident that the simple circuit r_3 is in parallel with the complex circuit just described. In the complex circuit r_5 is in parallel with r_1 and r_2 in series. Therefore, if we represent the joint resistance of this part of the circuit by R', then

$$R' = \frac{1}{\frac{1}{r_1 + r_2} + \frac{1}{r_5}} = \frac{1}{\frac{1}{2.5 + 7.5} + \frac{1}{6}} = \frac{1}{\frac{1}{10} + \frac{1}{6}} = \frac{1}{\frac{8}{30}} = \frac{30}{8} = 3.75 \textit{ ohms}$$

R' is in series with r_4, hence the resistance of the complex circuit is $R'' = R' + r_4 = 3.75 + 9 = 12.75$ ohms. Then the joint resistance of the total circuit is

$$R = \frac{1}{\frac{1}{R''} + \frac{1}{r_3}} = \frac{1}{\frac{1}{12.75} + \frac{1}{6}} = \frac{1}{\frac{18.75}{76.5}} = \frac{76.5}{18.75} = 4.08 \textit{ ohms}$$

Then the total current $I = \frac{E}{R} = \frac{75}{4.08} = 18.38$ amperes.

Since full pressure is applied across r_3, $i_3 = \frac{E}{r_3} = \frac{75}{6} = 12.5$ amperes. Full voltage is also applied across the complex circuit R'', hence, in this circuit the current $I' = \frac{E}{R''} = \frac{75}{12.75} = 5.88$ amperes. All this current flows through r_4, therefore, $i_4 = I' = 5.88$ amperes. After the current passes through r_4, it divides at C, part of it going through r_5 and part going through r_1 and r_2 in series. The voltage drop across r_4 is $e_4 = r_4, i_4 = 9 \times 5.88 = 52.92$ volts. $E' = E - e_4 = 75 - 52.92 = 22.08$ volts available between C and A, from which $i_5 = \frac{E'}{r_5} = \frac{22.08}{6} = 3.68$ amperes, and $i_1 = i_2 = \frac{E'}{r_1 + r_2} = \frac{22.08}{2.5 + 7.5} = 2.2$ amperes. The sum of i_5 and i_1 or i_2 is $3.68 + 2.2 = 5.88$ amperes, which checks up with i_4 the current flowing in r_4. This is as it should be.

In Fig. 1 if the resistance of each half of the armature winding from the positive brush around to the negative brush is 0.5 ohm, and there is connected between the brushes a resistance $L = 4.75$ ohms, what current will flow in the external circuit and in each half of the armature winding when 150 volts is being generated in the winding? Also, what will be the value of the volts across the brushes when the external circuit is connected?

An owner of land joining a stream above an existing dam loses all right to enjoin a raising of the dam, although that causes overflow of his lands, where no objection was made while the new structure was being constructed, and he maintained suits to collect damages for the injury done his property, without then seeking to enjoin further maintenance of the dam at its increased height. In addition to laying down this rule of law in the case of Holcomb vs. Alpena Power Co., 164 Northwestern Reporter, 470, lately, the Michigan Supreme Court also decided that where land is permanently flooded by a dam; the owner's damages should be computed in full in one suit on the basis of the excess of value of the land unflooded above its value as flooded.

Possible Saving in Avoiding Leaks in Boiler Setting

By J. M. Aarons

Some well-known truths are pointed out. Air leakage through boiler settings, due to cracked settings and porous bricks, can be reduced to a minimum by coating the brickwork. The present coal situation is bringing home the facts set forth.

SUPPOSE that 150,000,000 tons of coal could be deposited in the bunkers of the coal users of this country during the next twelve months without any effort on the part of either the mines or the railroads. This would mean that the fuel shortage would not only be overcome, but there would be a large surplus for export. This 150,000,000 tons is the estimated amount annually wasted by the coal users of this country, and the fuel shortage may therefore be charged directly to waste.

Engineers throughout the country have for years been pointing out the possibilities of increased efficiency in the boiler room. Generally speaking, little attention has been paid to them. The executive heads of manufacturing concerns do not, as a rule, make a study of their boiler-house conditions. This part of their operation is looked upon as a hot and dirty place. Combustion, as far as they are concerned, consists in starting a fire and shoveling on sufficient coal at intervals to keep up the steam pressure.

Coal Bills Considered Necessary Evils

Coal bills always touch the "sore spot," but they are looked upon more or less as necessary evils—something to kick about on the first of each month and then forget. Until recently, if the coal bill was 15 to 30 per cent. higher than it should be, it was nobody's business as long as the man who "paid the piper" was indifferent. Today things have changed and every pound of coal wasted is a black spot against the one who sanctions it.

How can coal be saved? When it is taken into consideration that a ton of good-grade coal delivered to the plant contains approximately 29,000,000 B.t.u. and that the average plant delivers to the point where power is used only about 555,000 B.t.u., it will be seen that an enormous waste is taking place somewhere. Part of this loss is unavoidable, but a large percentage of it is due to carelessness in operation and to neglect.

By far the greatest waste is caused by the large amount of excess air that is permitted to enter furnaces and boiler settings and to escape up the chimneys, carrying away heat that should be utilized to do useful work. This unnecessary excess air is admitted in two ways—first, through uneven fires which leave part of the grates bare and, second, through pores and cracks in the boiler settings. Loss due to uneven fires is chargeable directly to improper operation. Every fireman knows that to get the greatest capacity out of a boiler the entire grate surface must be covered with burning fuel and that there must be no holes or bare spots, but apparently many do not appreciate that an even fire is necessary if the fuel is to be burned efficiently. If a few simple instructions along this line were given and the firemen were required to follow them, a tremendous saving would be effected.

The loss due to leakage through boiler settings is even more important because it is less easily detected. If a fire is in improper condition, one look into the furnace reveals the fact, but leakage through settings is not so apparent. There is a certain amount of leakage around doors and boiler drums, but most of it filters through what appears to be a solid brick wall. The heating and cooling of the brickwork opens up a large number of small cracks which increase the leakage without giving a setting the appearance of being in bad condition. The leakage through boiler settings reaches greater proportions than is apparent from an inspection of the brickwork and may be as great as one-half of the amount of air supplied for combustion. This represents a large preventable loss, and one which may go on unnoticed because there is no outward indication that it actually exists. Moreover, the loss due to infiltration of air to the boiler settings is not intermittent but represents a continual source of fuel waste from the time the boiler is put in service until it is taken out. In fact, the condition is gradually aggravated, week after week, as the settings become more cracked and porous.

A large plant recently attempted to purchase two 500-hp. boilers. The delivery on this equipment was so far off that a serious problem faced them. The services of an experienced combustion engineer were engaged to see what improvement could be made in the existing plant. Analyses of the flue gas were taken, and readings as low as 2.4 per cent. CO_2 were secured on two of the boilers. This represented an excess air condition of about 800 per cent. Further investigation disclosed large openings in the settings, and open doors into the combustion chamber were admitting sufficient air to absorb practically all the heat liberated by the fuel burned in the furnaces.

Tight Settings Effect Large Coal Saving

With all settings made tight, which required but a few days' work, the new boilers were no longer necessary, and a large saving of coal was effected. Although this is an extreme case of waste, due to air infiltration, it serves to emphasize the necessity for tight settings. In fact, the heat units actually used in the average boiler room when compared to the heat units that can be obtained under proper operating conditions and with tight boiler settings, if put on a dollar and cents comparative basis, are equivalent to paying $5 for only $2.86 worth of coal.

Any handbook or treatise on boiler and furnace efficiency will point out the necessity of keeping the settings tight. The efficiency guarantee of any stoker company has a clause referring to tight boiler settings that qualifies their guarantee. In spite of all this the boiler settings in 95 per cent. of the plants leak air excessively.

Every crack and crevice represents waste, and every brick and mortar joint, no matter how good it may look, is passing a certain amount of air. Leaky boiler settings not only seriously affect the coal bill, but materially reduce the capacity of the plant. Many manufacturing concerns that are now crippled through lack of steam could sail merrily along with steam to spare, by simply coating the boiler settings.

The capacities of most chimneys are limited and can handle only so much air as they are not usually generously designed. The higher the temperature of the gases entering the chimney the greater the velocity through it. Its duty in all natural-draft installations is to pull the required amount of air through the fuel bed and to carry off the resultant gases of combustion. If cold air is allowed to leak into the settings, it lowers the temperature of the gases, slows up the velocity through the chimney, puts an unnecessary burden on it and cuts down the capacity of the plant.

There are usually two sides to a question, but there is positively but one side to this one. There can be no argument brought to bear against a tight boiler setting. The first step toward economy in the boiler house should be to cover all brick settings and stacks with a suitable air-tight coating. The material of this coating should have sufficient elasticity to expand and contract with the brickwork and also be capable of standing considerable heat and temperature changes and remain plastic for a long period. Above all, it should adhere firmly to the brickwork and not crack or peel off. There are several compounds that meet these requirements. They are cheap, easily applied and present one of the best investments that can be made.

No matter what improvements are contemplated in the boiler house, the settings should be coated. A fortune may be spent on instruments and boiler-house equipment, but the results striven for will still be missed if the boiler settings are leaky. Fuel represents 70 to 80 per cent. of the total cost of power. Is not 3 to 30 per cent. of this amount worth saving?

Unusual Design of Evaporator for Distilling Sea Water

Those who have to deal with the distilling of sea or other water or with evaporation problems of almost any kind will be interested in the design of the Lillie evaporator now being built by the Wheeler Condenser and Engineering Co., of Carteret, N. J. It is, as will be seen from the illustration, a modification of a regular Lillie sextuple-effect sea-water distilling apparatus. Two of these now under construction are to be operated by steam up to 60 lb. gage pressure or at any lower pressure.

The point that will catch the veteran's eye is the employment of four condensers, side by side, as shown in the illustration. This unusual arrangement of condensers permits seven different combinations of operation, as follows:

It may be operated as one single effect or more single effects; it may be operated as one or more double effects with vapors reversible in each; it is possible to operate it as a triple effect, or as two triple effects with vapors reversible in each; it is impossible, of course, to operate it as two quadruple effects, but every effect may be utilized by grouping as one quadruple effect and one double effect, in both of which the vapors are reversible; it may be operated as one vapor reversible quadruple effect with both end effects or either end pair of the section cut out; with one effect at either end cut out, it may be operated as a vapor reversible quintuple effect; lastly, it may be operated as a vapor reversible sextuple effect.

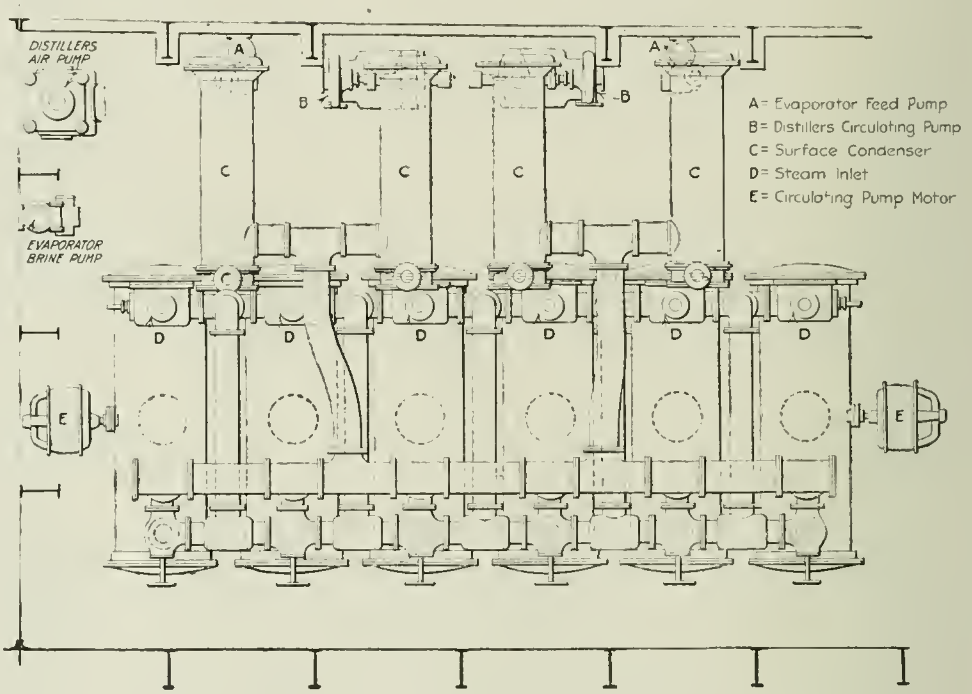

DIAGRAM OF THE LILLIE SEA-WATER EVAPORATOR

It is evident that should a mishap occur at either end, in the middle or anywhere else, there is little danger that this evaporator will be put out of commission entirely.

Fuel Consumption of Low-Compression Oil Engines

By L. H. Morrison

THE builders of low-compression oil engines have quite generally adopted the following guarantees of fuel consumed per brake horsepower per hour at various loads: Full load, 0.100 gal.; three-fourths load, 0.110 gal.; half load, 0.125 gal. These performances can be attained in actual service, so long as the wear on the engine is not excessive.

All builders claim that their engines will operate on the heaviest of oils, as well as on other grades up to kerosene. Although any oil engine will work well with a crude oil that contains a considerable percentage of the lighter oils, the service will not be satisfactory if the crude has an asphaltum base. When such oil is used, deposits of carbon and asphaltum occur in the cylinder and cause rapid cutting. The same is true of any fuel oil having an asphaltum base. The wear on the cylinder is particularly heavy if the oil contains dirt and grit.

If a fuel oil is decided upon, it is advisable to purchase a filtered oil, usually sold as "Diesel fuel oil." This will probably cost from one to one and a half cents more per gallon than unfiltered fuel oil, or "boiler oil," but in lessening the wear on the cylinder, reducing the cutting of valves and seats and decreasing trouble in general, it is well worth the difference in cost.

The best all-round fuel is without question a distillate of about 32 deg. Baumé, because it is light enough to burn completely at all loads. Experience has proved that distillate is the proper fuel for any low-compression engine. These remarks apply specifically to asphaltum-base oil; with a paraffin-base oil it seems that any grade of fuel oil or crude may be used successfully.

Amount of Sulphur Should Be Limited

In the purchase of the fuel, limits should be placed on the amount of sulphur in the oil. While one-fifth of one per cent. of sulphur is as much as ought to be allowed, a greater percentage is usually found. One engine builder suggests the following requirements, which have been found satisfactory in connection with his own engines: Specific gravity, not below 26 deg. B.; sulphur, less than 0.5 per cent.; water, less than 0.5 per cent.; coke, not over 3 per cent.; fraction which will distill off below 360 deg. C., at least 60 per cent.; oil to have a heating value of at least 18,500 B.t.u. per lb., and to be free from grit or dirt.

On the basis of brake horsepower, the thermal efficiency at full load will be in the neighborhood of 19 per cent. On the basis of indicated horsepower, disregarding the friction and the power required to run the air compressor, the efficiency will be approximately 23 per cent. If efficiencies much greater than these are guaranteed, it will usually be found that the engine is not of the low-compression type, but belongs to the semi-Diesel class, in which the temperature range allows a greater efficiency to be obtained.

In case the engine drives an industrial load, the best method of drive is by means of a belt. Many engineers show a preference for a clutch coupling connecting the engine shaft to the driven shaft; but with this arrangement it is a hard matter to keep all the bearings in line, and the usual result is rapid wear of the bearings and the clutch friction blocks.

By using a friction belt pulley, the engine can be started under no load and brought up to speed before the load is thrown on. Driving by belt allows the shaft bearings to keep their alignment with greater ease. The wear on the engine and lineshaft bearings is less, and the drive is more flexible.

In an installation in which the engine drives an electric generator, the rotor should, if possible, be placed directly on the engine shaft. In the past it has been the general custom to use a waterwheel or gas-engine type of alternator with self-contained bearings and shaft. This shaft was connected to the engine shaft by a flexible coupling or a flange coupling. Such a method involved at least one extra bearing or was hard to keep aligned. In the later engines an extended shaft and an outboard bearing are generally used. The rotor can be pressed on the shaft extension. Such an installation is more attractive and easier to keep in good shape.

The question often arises as to the possibility of paralleling two alternators driven by low-compression engines. If the engines are of the single-cylinder type, the synchronizing will be more difficult than if multicylinder engines are used. This is due to the large angular variation in the speed of the single-cylinder engine, although, of course, the use of extra-heavy flywheels will eliminate part of this trouble. As a consequence, there are more installations in which paralleling of the units is accomplished by using multicylinder engines than by single-cylinder engines.

It is well to have the alternators equipped with squirrel-cage windings on the rotor to reduce the cross-currents. Another good plan is to use exciters large enough so that one of them will be able to furnish sufficient current for both generators.

Low-Compression Type Suited to Small Plants

The low-compression engine has its field of usefulness. In industrial plants using less than a hundred horsepower, this type is quite suitable. While the history of the usual installation is one of expensive repairs and shutdowns, this is not really the fault of the engine. It has been customary for builders to claim that experienced attendance was not necessary; but many purchasers who have acted on this statement have learned how little truth there is in it. Given the care that a Diesel engine or a Corliss steam engine receives, the low-compression engine will operate satisfactorily.

While fuel oil was cheap, the saving of the Diesel engine over the low-compression engine was not great in the smaller sizes; as a result, the low first cost of the low-compression engine was the motive that caused many to be installed. With oil costing about five cents a gallon, the Diesel engine will undoubtedly be favored over the former type even in sizes less than one hundred horsepower.

Falling Chimney Wrecks Part of New England Factory

A part of the three-story frame building of the Sprague Box Co., at Lynn, Mass., was wrecked by a falling chimney recently, causing four fatalities and injuring a number of employees. The chimney failed during a gale estimated at 60 miles per hour, and had the accident occurred later in the day, the loss of life would unquestionably have been much greater. The chimney was a brick stack of rectangular horizontal cross-section, about 3 x 5 ft. inside dimensions and approximately 70 ft. high. As shown in Fig. 1, the original of which was made on the spot by a representative of *Power*, the chimney was carried upward from the boiler house of the factory along the outer wall, to which it was attached by iron straps about half-way up and also at the roof level. It extended above the roof for about 35 ft. The original chimney was built eight years ago, and twelve months ago about 8 ft. was added to its height, the stack being guyed to two parts of the factory building.

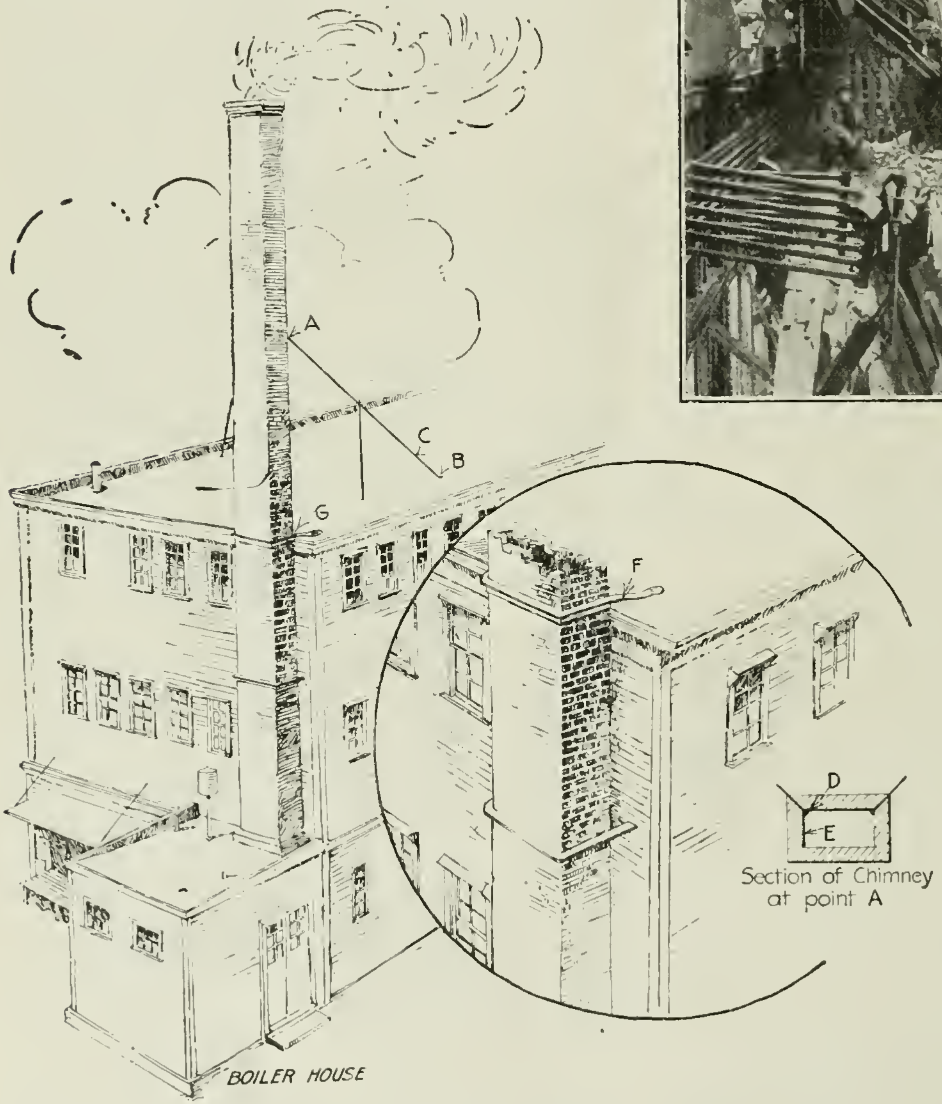

FIG. 1. DETAILS OF THE CHIMNEY, METHOD OF BRACING AND POINT OF FAILURE

In Fig. 1 *A* represents the two anchorages to the chimney and *B* the anchorages to the roof; the rods *C* are 1 in. in diameter and about 30 ft. long; *D* is an angle iron on the inside of the chimney; *E* represents the thickness of the chimney, 8 in.; *F* is an iron strap at the roof level, and *G* represents the point where the chimney broke off.

FIG. 2. THREE FLOORS WERE DEMOLISHED

In giving way under the gale, the stack broke off at the roof level. It fell intact into the factory, demolishing three floors covering a panel or bay about 16 ft. wide and 40 ft. long, Fig. 2. The anchorages of the brace rods in the stack held. The wooden anchorages of the rods in the building structure were carried away with the rods, and the only bracing support of the stack was the stiffness of these rods. Foundation and straps were in good condition when inspected. It appears that the chimney was ill-proportioned for the height to which it was carried and that its anchorages to the roof were inadequate in size and number, guying being on one side only. All possible aid was extended to the victims of the disaster by the local branch of the Red Cross, the Lynn works of the General Electric Co., the Lynn Gas and Electric Co., J. B. Blood Co., and others, and fortunately no fire occurred.

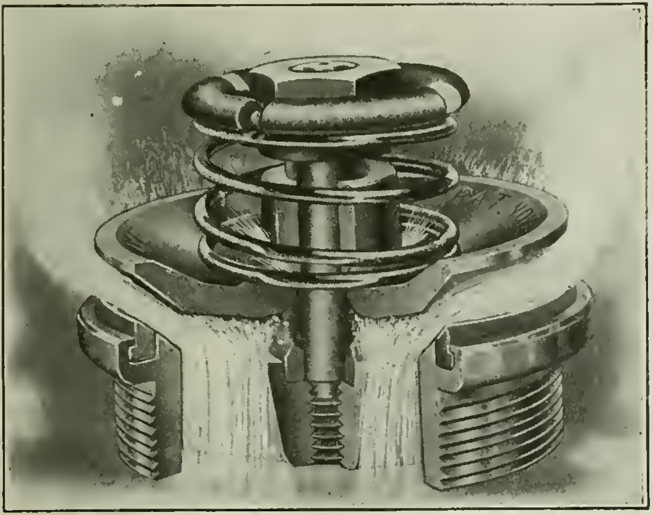
The accident occurred at 7:45 a.m., and at 5 p.m.

on the same day the débris had been removed, a new roof erected, and the chimney replaced by a 2.5-ft. steel stack 30 ft. long, erected upon the remaining portion of the brick stack. The plant resumed operation on war orders the morning after the accident. About 5 ft. of new brickwork was built upon the upper end of the old stack in adding the new section. Two courses of bricks formed the stack proper, the walls being 8 in. thick.

Scoville Pump Valve

A metal-to-metal pump valve sealed by compressible composition rings of special form is being made by the Scoville Pump Valve Co., Chicago, Ill. As shown in the illustration, the valve disk is beveled on its outer circumference and also around the hole for the stem. In grooves around the stem and in the seat of the valve the composition sealing rings are inserted. The pressure of the fluid forces the rings against the beveled edges of the valve, making the metal-to-metal joint tight, and as the rings come in contact with the valve before it is fully seated, there is little opportunity for slippage.

Wear upon the seals is small as the valve does not seat directly upon them, and renewal is comparatively simple and inexpensive. Another advantage claimed for the beveled valve is a reduction in friction and loss from eddy currents over a flat disk in which the fluid flow is at right angles to the plane of the valve. Standard and pot types of valve are made.



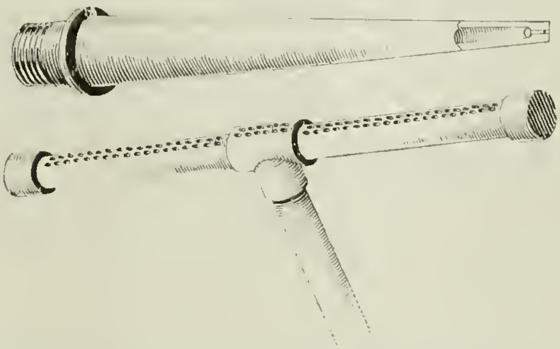
SCOVILLE METAL-TO-METAL PUMP VALVE

Compressed Air for Cleaning Motors

By D. R. Shearer

In a great many manufacturing plants, especially those working in wood or a similar material, the driving motors have a tendency to become clogged with dust in a short time. Such accumulation of dust is a fire hazard, particularly if the motors are overloaded and liable to have coils burn out; and if a motor is not overloaded, it may heat if the air ducts are filled with dust. Moreover, the motor is not able to carry the peaks when called upon, for the reason that the additional heat cannot be dissipated. Motors should be cleaned frequently, but such cleaning with the means ordinarily at hand is a rather difficult procedure since the air ducts are usually small and difficult to clear with a brush. The windings may be brushed off externally, but such cleaning does not reach the real seat of the trouble.

One of the best methods is compressed air under considerable pressure. If the air is not available from some source already in use, it is advantageous to use a small motor-driven compressor and a storage tank. The compressor should have a capacity of from 4 to 10 cu.ft. of air per minute at a pressure of 100 lb. per sq.in., and the tank should hold from 40 to 100 cu.ft. This size will take care of the average plant.



NOZZLES OR TOOLS FOR CLEANING WITH AIR

In piping a factory the air line can be 1-in., $\frac{3}{4}$-in. and $\frac{1}{2}$-in pipe. Since the amount of air used in cleaning any one motor is small, a large pipe is not necessary. An outlet with a valve should be placed near each motor, or if they are grouped, several motors can be reached from one outlet with $\frac{1}{2}$- or $\frac{3}{8}$-in. hose; the smaller size is more easily handled. The nozzles can be made up of brass rod of suitable sizes and shapes, one of which is shown in the illustration. It is necessary, however, to use nozzles with small openings as a large nozzle opening would consume too much air. Probably the most useful sizes would be $\frac{3}{32}$-, $\frac{1}{16}$- and $\frac{3}{64}$-inch, and these three nozzles will meet most conditions.

Sometimes it becomes desirable to clean surfaces with air; for instance, the walls or ceilings of the buildings. This may be done with a tool made from $\frac{3}{8}$- or $\frac{1}{2}$-in. pipe in which there are a number of holes, as shown, to form a "brush" of escaping air. For ordinary purposes holes of about $\frac{1}{32}$ to $\frac{1}{64}$ in. can be used.

These small nozzles do not clog readily if all the scale and dirt is blown out of the piping. As an investment such a cleaning system will be found to pay for itself in the reduction of motor troubles and the decrease in fire hazard.

Carbon in Steel

There is more or less uncertainty in the mind of the average reader in regard to carbon in steel and how it can be got there. While there are many ways of introducing carbon into iron, one of the most direct is to throw charcoal into a ladle being filled with molten iron—simple as sprinkling salt in soup and the determination of the proper amount is the same; that is by sampling.

Centralized Mine Plant

By C. C. Muldner

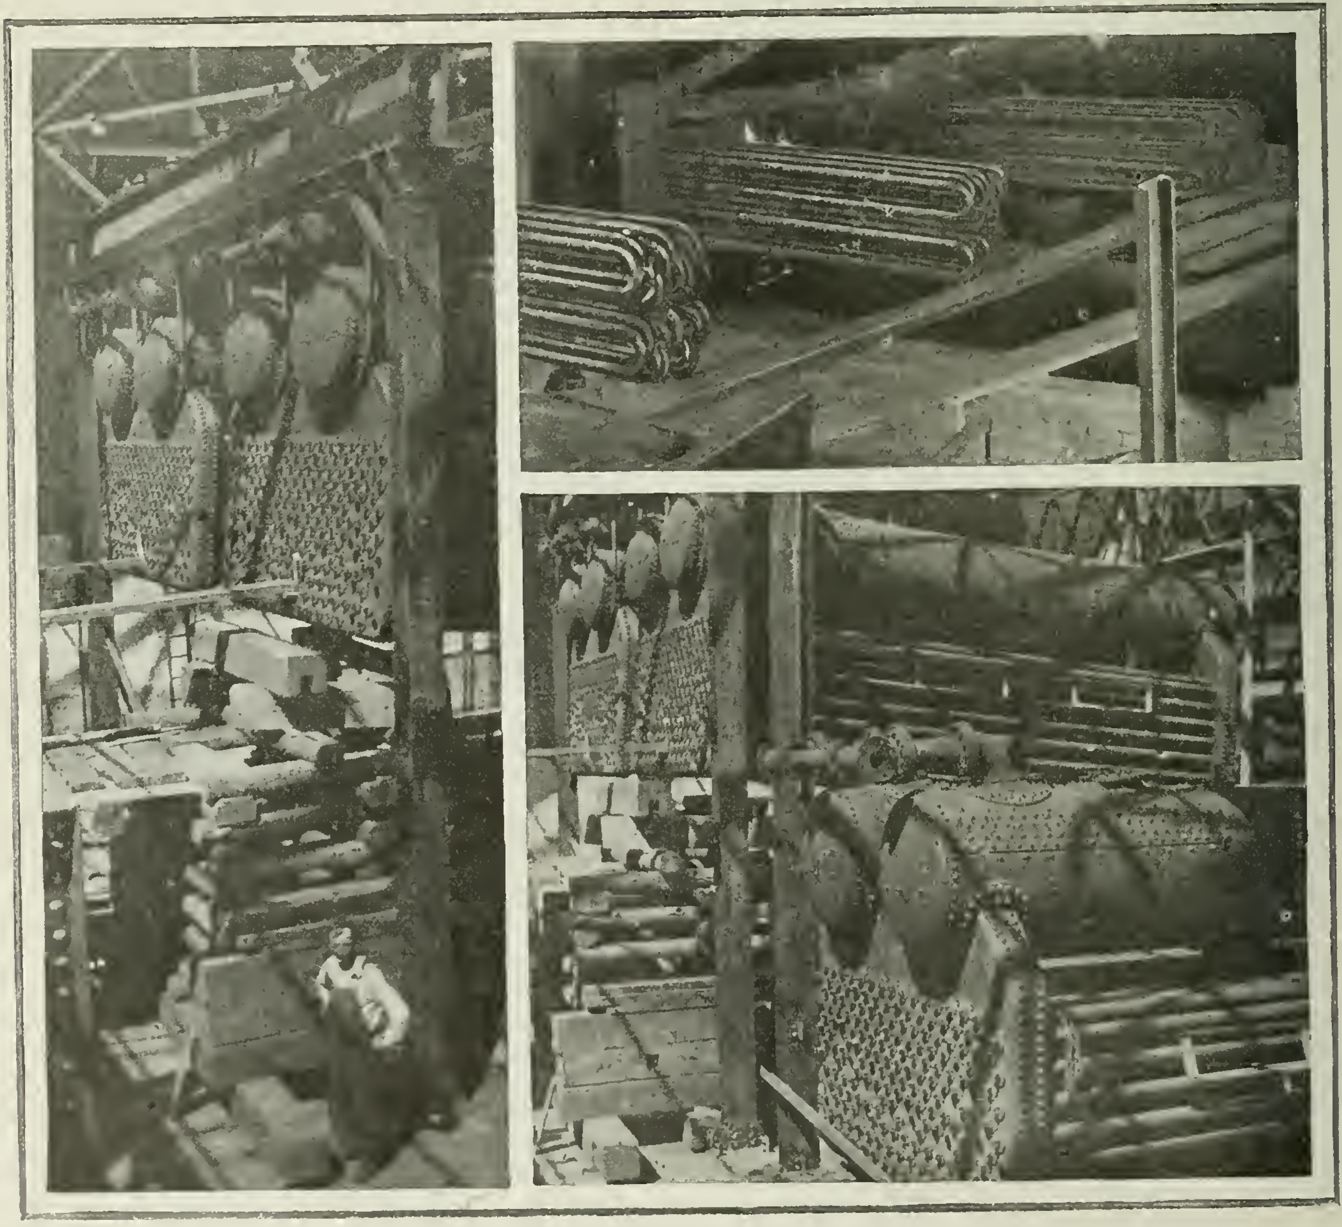
The illustrations show the boilers in course of erection in the new addition to the power plant of the Oliver Iron Mining Co., at Ironwood, Mich.

The chief feature in this setting is that two 25-ton (450-hp.) Heine boilers are hung on one gallows, there being no supporting column in the division wall between them. The overhead support consists of two 24-in. I-beams 27 ft. long, supported by two 10-in. H-beams, eliminating the usual column in the division wall, which, being completely bricked in, deteriorates rapidly, causing serious trouble. The height of the setting can be judged from the height of the man standing on the floor level and the tops of two return-tubular boilers in the background, by means of which it is expected to eliminate smoke and greatly increase the furnace efficiency and pay for the extra first cost in a short time. The temperature control connected with the superheaters maintains any desired superheat within five degrees.

This plant will be used as a central station for all the mines in the vicinity belonging to the Oliver Iron Mining Co., of which there are about thirty, to be linked together with about 14 miles of tunnels. Cables and steam pipes will transmit power, light and heat to each mine. Eventually, the mines will be electrified, thus doing away with the numerous individual boiler plants.

This is an example of the present tendency to centralize mine power plants and, in the case of coal mines, to produce electric current for distribution and sale at the pit mouth, where low-grade fuel can be profitably utilized by combining high boiler setting and superheaters in large units; and with stokers and coal- and ash-handling machinery, the cost of producing steam should be reduced to the minimum.

The transfer of electric current long distances involves a loss, of course, but it often costs much less than the hauling and handling of coal from the mine to the market. Time was when crude oil was hauled from the wells to the refineries; nowadays it is pumped for distances of several hundred miles.



TWO BOILERS SUSPENDED FROM A SINGLE GALLOWS FRAME; HIGH SETTING AND SUPERHEATERS

Putting Their Houses in Order

THE employers have begun to set their houses in order. Some employers, not all. Careful study is beginning to replace indifferent handling of the labor problem. Necessity is forcing a modification of the autocratic policy. The worker will no longer be a chattel. He demands to be treated as a human being. His aspirations must be consulted.

There was plenty of reason in the past for the employer changing his attitude. Where he did not have strikes, he found at least indifferent and consequently wasteful labor interest. His dominant thought, though, was to hold all power. He feared that any injection of the milk of human kindness would lead the men to believe that he was weakening, that kindness was the resort of waning strength.

Yet around him there were plants that continued successful even though the men were treated like humans; aye, that increased their profits through greater efficiency and greater labor stability. Gradually the public, learning faster than the owner, forced upon him shorter hours, accident-prevention measures, proper sanitation, workmen's compensation. And lo, the industry was the gainer. There was physical response to the improved conditions; and just as surely, response in spirit, even if unconscious.

Still, the absolutism in management remained. The changes were forced, not voluntary.

Then came the war. Labor, from receiving an indifferent interest from the employer, began to get his chief attention. The supply was ostensibly short.

For a decade those who thought deeply on management problems have urged a closer study of the human element. Management inefficiency, as affecting the worker, had been berated. The value of intelligent employment and promotion systems, involving a close study of the aptitudes, ability and ambition of each employee, had been emphasized. All to no avail—until the war came.

Now the demand for skilled employment managers is far greater than the supply. With an apparent labor shortage the wisdom of putting each man in his best place, of giving him the highest type of work he is capable of doing, of encouraging him to improve himself, has been apparent.

Intelligent employment methods must become universal. They are necessary for the development of the highest efficiency of the individual as an individual and as a member of an industrial organization. Moreover, they bring employee and employer into close, sympathetic touch. Each will profit from the experience of the other.

Such contact, too, is a necessary preparation for the inevitable—coöperative management. Any scheme that is not based on confidence and sympathy will fail. If coöperative management is accepted grudgingly, if an artificial structure of labor participation in plant control is nullified by an unjust employment system, there is sure to be strife. The insincerity will prevent effective coöperative work.

And since coöperative management is to be expected as a war product, it behooves industrial leaders to prepare for the day, to put their houses in order. There must be in each plant someone whose duty is to know the worker, whose seat at the council table is that of the employee's advocate.

Such is the way that progressive employers are preparing for the industrial change that will inevitably follow the war.

Shutting Down the Isolated Plant

THERE are two sides to every question, and this applies to the methods of supplying power to manufacturing plants. Most manufacturers who operate their individual power stations do so because they find that power can be produced cheaper than it can be purchased. To be sure, the coal shortage has caused annoyance and in certain cases some losses, but it is not evident that the situation has been such as to warrant eliminating these isolated steam plants as advocated by the following extract from a recent editorial appearing in *The Central Station:*

> Never was the time more ripe for urging the shutting down, if not eliminating entirely, for business as well as for National reasons, the isolated plants which could and should be served by the central station. The stubborn owners and operators of isolated plants, and the word stubborn fits the majority of these cases, have certainly had their full measure of worry and loss during the past two months, due to the coal situation. Yet no amount of accurate operating figures submitted to them, previous to the present conditions, by central-station engineers, could move them to action.

As has been stated many times in *Power*, there are some types of isolated steam plants that should either put in new equipment or purchase power. There are others that should use purchased power part of the time, as for instance, night runs during the months when no heating is required and the load is light, but should use their own power during the yearly day run with a heavy load, and heating during the winter months. Other plants should never purchase power, but should produce their own at all times.

We agree that the isolated-plant owners are "stubborn," when it comes to discarding their power plant and substituting purchased power, but if their plants are run in an economical manner, there should be no cause for surprise as to the admission made in the editorial mentioned that "no amount of accurate operating figures submitted to them, previous to the present conditions, by central-station engineers, could move them to action."

We very much doubt that the same "accurate figures" will move them even now after the period of "worry and loss." Most isolated-plant owners have an ear to the ground when it comes to dependability and economical service, and the plight that many manufacturers have found themselves in during the last two months can hardly be an incentive for them to continue central-station service or to induce isolated-plant owners to abandon an expensive and dependable plant equipment for a service that is not as dependable and does not always serve.

Some of the recent newspaper headlines relating to this matter tell the story, but they can hardly be considered as evidence favorable to the wiping out of the isolated power plant. A Nashville, Tenn., paper has this headline: "ELECTRIC POWER CANNOT BE USED. INDUSTRY IN NASHVILLE WILL ALMOST WHOLLY CEASE TOMORROW." A New Jersey paper came out with the heading: "ALL DEPENDENTS UPON P. S. SERVICE ARE TIED UP. OFFICIALS OF THE PUBLIC SERVICE ELECTRIC COMPANY TODAY ESTIMATE THAT 2500 PLACES OF BUSINESS ARE SHUT DOWN IN HUDSON COUNTY." Another heading reads, "POWER OFF SEVERAL DAYS," and still another: "POWER OFF ALL THIS WEEK. INDUSTRIES PRACTICALLY AT A STANDSTILL. 15,000 IDLE HERE." These are only a few of the many that could be cited.

Many manufacturing plants are engaged in making war materials, and the sudden expansion of power requirements has forced them to purchase power to meet the additional demands upon their steam plants. Although big and little factories engaged in war materials have been hit by the failure of the central station to provide power, it is significant to note, according to newspaper articles, that "the —— factory operated in part, however, because it has a plant of its own. The plants of the —— Co., the —— Co. and the —— Co. are operating today because these concerns can generate their own electricity. Practically everything else in the city is at a standstill."

Central-station representatives are undoubtedly using the past and present fuel difficulties as a lever to pry isolated plants into taking their current. In fact one such gentleman stated in this office that this was the time to cover the isolated-plant field in a central-station canvass. Some will fall for it, but with the most of them no amount of "accurate operating figures" submitted to them by central-station engineers will "move them to action" that is against their own interest.

Government Coal-Price Regulation

THE regulation of coal prices by the Fuel Administration is the first attempt ever made, at least on a large scale, by the United States Government to fix and establish prices for any of the great industries. It is very important to both the public and the coal industry that the prices so fixed should be based on accurate information as to the conditions prevailing in different fields, and that, when once this information has been received, the right principles should be employed in making use of this information.

The Fuel Administration believes that it has devised a speedy and accurate method for using the cost information which it has in hand, and that it has worked out the fundamental principles which should guide it in considering applications for modifications of coal prices. It is the purpose of the Administration to announce decisions on all applications for the price revisions now before it, prior to April 1, 1918, and, prior to that time, to make such changes in the classification as seem to be necessary, in order to relieve uncertainty on this score as far as possible before the beginning of the new coal year.

By this statement, the Fuel Administration does not wish to be understood as stating that the examination of the prices now being made will complete its price work. On the contrary, it will continue to collect and study facts relating to the cost of production of coal and the prices at which it is sold. It will make such further readjustments from time to time as are necessary to keep the price on a scale fair to the public, fair to the coal industry and sufficiently high to encourage production. It hopes, also, to take measures in the very near future to encourage and insist upon the use of less wasteful methods of mining, the sale of clean coal and the more definite recognition of the different qualities of coal in the Government prices.

Rate Fixing

THE Supreme Court has decreed that a public-utilities corporation is entitled to a profit on a "fair value" of its property. Several public-service commissions consider a fair value the cost of reproduction at present prices, less depreciation.

Public-utilities corporations are actually going before public-utilities commissions and pleading for raises in rates which will enable them to pay a profit on values of their property based upon the inflated war prices of last year.

And they do this in all apparent seriousness and with the evident expectation of getting away with it. Allowable profit should be based upon the cost of the service rendered and not upon an indeterminable value of the plant required to produce it.

Frank Baackes, vice president of the American Steel and Wire Company, in criticizing the Fuel Administration, says: "You cannot expect a tailor to operate a blacksmith shop successfully, nor can we expect too much of an administrator who was nothing more than a professor of economics."

Probably a representative of the coal producers could have induced his associates to produce more and cleaner coal at a less price; and could have made a crippled railway system distribute it to better advantage. Eh?

The Toronto *Call* announces that Patrick K. Gallagher, of Nelson, B. C., has developed an internal-combustion engine in which oxygen will take the place of gas or oil. It won't do, Patrick. Oxygen is working now in every kind of combustion engine, internal and otherwise, even in the mysterious motor processes of the animal organism; but it needs fuel or food to work with. If you want to make a real fuss with your idea, keep people guessing about it, like Garabed.

The essentials—Students of Divinity and Dentistry are exempt from the draft; students of engineering are not.

Correspondence

Grate Area and the Underfeed Stoker

With hand-fired grates or overfeed stokers operating on natural or induced draft, the question of grate area is an important one. With natural draft the furnace suction that can be obtained is limited by the height of the stack it is feasible to build. In the case of induced draft, infiltration losses through the boiler setting and grates, which become prohibitive at high negative pressures, limit the possible furnace suction. The amount of coal that can be burned per square foot of grate is limited by the available furnace suction, and consequently, if it is desired to double the capacity of a boiler, it is necessary to double the amount of grate surface.

In the case of the underfeed stoker, grate area is not of so much importance. The capacity that can be obtained from the stoker is dependent only to a small degree upon the grate area. The amount of coal that can be fed by the stoker is limited only by the mechanical strength of the stoker parts. To burn this coal, it is only necessary to provide a sufficient blast pressure under the grates, sufficient openings through the grates and means for keeping the fuel bed broken so that the air may find a passage up through it. The draft suction in the furnace of an underfeed stoker should be kept as nearly equal to the atmosphere as possible at all ratings to prevent infiltration and also to stop gases escaping from the furnace into the boiler room. The resistance of the fuel bed is taken care of by the forced-draft pressure under the grates. To a certain extent, the resistance of the fuel bed is inversely proportional to the percentage of volatile in the fuel. The higher the volatile the less draft pressure under the grates necessary for burning a given amount of fuel. Infiltration losses actually decrease at high ratings. The reason for this is that the limit to capacity with an underfeed stoker is usually set by the ability of the chimney or induced-draft fans to get the gases away from the furnace without permitting a pressure in the furnace. The capacity limit is usually not due to inability to burn sufficient coal.

With the underfeed stoker combustion efficiency does not depend to any great extent on the grate surface, but is dependent more upon distillation or retort volume and total volume of coal in the furnace. To show this the underfeed stoker may be compared to a continuous gas producer. It is well known that the highest efficiency of combustion would be obtained from a gas producer with a fire bed several feet thick. The underfeed stoker and the gas producer are similar in the following functions: (a) Distillation of gas by approach to hot zone; (b) mixture of gas and air in the fire, using the tortuous passage between lumps as a means of thoroughly mixing volatile matter and air; (c) heating of the mixture to a high temperature as it passes through the topmost layer of the fire.

The great difference between the underfeed stoker and the producer is that the producer is not intended to complete combustion but only to produce a combustible gas, whereas the stoker must not only produce the gas but burn it and the resulting coke. The temperature of the fire of the underfeed stoker is much higher than the producer, and this sets a limitation to pursuing the analogy too far. The high temperature with the underfeed stoker causes the formation of masses of clinker, and if a great depth of fuel bed were used with the stoker, it would be impossible to keep it broken up and free from clinker by any practical method of stoking or mechanical poking. Within the limits of the clinker problem, that stoker having the greatest distilling volume will have the highest combustion efficiency. The higher the percentage of volatile in the coal, the greater the necessity for large retort volumes in order to get high capacity and efficiency.

The difficult feature of coal combustion is not the burning of fixed carbon, but of volatile matter. The burning of volatile matter is a function of the relative thoroughness of mixing air and gas and of temperature. The temperature must be kept above the ignition point or the flames will be extinguished. The thoroughness of mixing introduces the element of time. If mixing is done in the fuel bed, the thoroughness will depend upon the length of the mixing passages; that is, the depth of the bed. If mixing were perfect in the fire bed, which might occur with a deep producer fire, there would be little or no flame, and surface combustion would practically result with a bed of hot coke as refractory material. If the depth of bed is insufficient for perfect mixing, flame occurs and furnace volume is then required to provide the length of path to complete the mixing. For the highest efficiency, combustion must be completed and flames disappear before contact with any heat-absorbing surface, otherwise extinction of the partly burned material occurs, usually with soot deposit, and part of the gases must escape unburned, unless secondary combustion can be established, as for instance, at the top of the first boiler pass.

In general the problem of combustion is that of carburetion, and the stoker might well be compared to a carburetor. The dictionary defines a carburetor as an "apparatus used to charge air or gas with volatilized hydrocarbons." The verb to carburize means "to combine or impregnate with carbon." A stoker fire, or the fire in any furnace, is a device for carburetting the air passing through the fuel bed. The hydrocarbons and carbon are volatilized by the heat, and then they impregnate the air so that it becomes a combustible gas. Combustion efficiency depends on the accuracy of the mixture. The capacity varies with the volume of air passed through the fuel bed and impregnated. Grate area is of some importance, but depth of fuel bed is the essential feature, for depth is what promotes better mixture of gas and air. Any carburetor device is efficient as it secures mixture in right proportions. Thus the tortuous passages through a deep fuel bed of small area are more effective than the relatively direct passages through a thin fuel bed of large area.

As an index of the value of an underfeed stoker, the relation between distillation or retort volume and total volume of coal is most important. By distillation or retort volume is meant the volume of coal in the retorts below the tips of the tuyeres or grates, including the throat under the front wall in front of the feeding plunger. By total volume of coal is meant the retort volume plus a one-foot thickness of fuel over the entire surface of the stoker. This one foot will allow for the usual thickness of 18 to 24 in. in the thickest part of the fire down to 6 or 8 in. on the overfeed section and the dump grates. This same comparison might be made by obtaining the ratio between retort volume and grate surface. Distillation and mixing of the volatile matter occurs clear to the surface of the fire so that the relation between total volume of coal and the square feet of grate is also important. Combustion of fixed carbon of course predominates near the surface of the fire, while in the retorts proper distillation and mixing is the sole function.

The most important function of the underfeed stoker consists in the burning of volatile matter. For this reason the best comparison of an underfeed stoker consists in getting either the ratio between retort volume and total volume or between retort volume and grate surface. The usual practice in figuring square feet of grate surface is to use the projected area of the stoker including dump. Combustion actually takes place with the underfeed stoker from the front wall clear back to the bridge-wall. The path of least resistance for the air through the fuel bed is generally toward the bridge-wall. Consequently, even if there is no definite air supply at the rear end of the stoker, there is still ample air coming through from the fuel bed above to maintain active combustion. For this reason it is perfectly legitimate to include dump-grate area when figuring the grate surface of an underfeed stoker. **F. H. Daniels,**

Worcester, Mass. Sanford Riley Stoker Co.

Turbine Accidents

The list of turbine accidents by C. H. Camp, in the Nov. 20 issue of *Power*, covering a period of seven years, justifies the present writer's claims for overspeed tests notwithstanding the small number of accidents due purely to explosions of the turbines. When one considers that in a period covering seven years the casualty companies, as the author states, can record only 19 accidents due to explosions, it is apparent that "turbines which have exploded due to overspeed or overpressure in the low-pressure stages have been very few."

In most cases the explosions or accidents were due not to inherent faultiness of the turbines themselves, but to causes separate from the turbines and mostly due to carelessness on the part of the operators or to improper electrical protection. It is not proposed nor intended to be understood that a 100 per cent. overspeed test on the turbine will make it safe against explosions. It will not be required if the trips and governors work properly; but if the governors should refuse to act, the additional factor of safety of a machine tested to a 100 per cent. overspeed would give the attendant, or watch engineer, an opportunity to trip the throttle by hand before the turbine rotor reached the breaking point.

From careful examination of the list of accidents submitted I am of the opinion that most of them were due to faulty and careless operation or attendance, as in well-conducted plants the engineer in charge makes it his business to ascertain that the governor does not stick and that the relief valve will relieve the pressure if need be. Relief valves, however, should always be fitted with safety measures, such as auxiliary tripping devices actuated by the governor of the turbines.

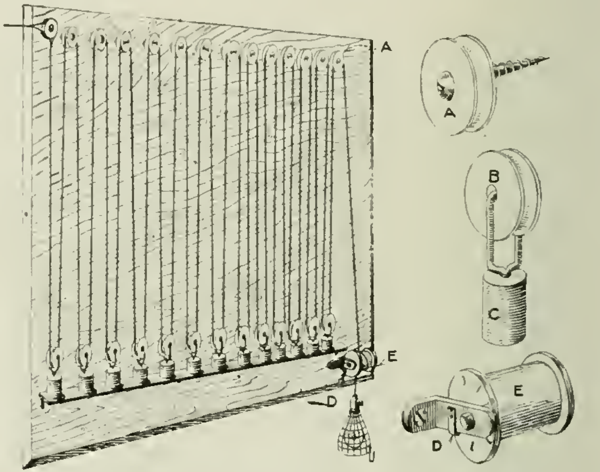
Adjustable Extension Lamp

Anyone who has worked in a shop, power plant or any place where a portable electric lamp is used, will quickly become impressed with the annoyance that the loose extension cord causes when thrown promiscuously about the floor. An efficient method of avoiding much of this annoyance is shown in the accompanying illustration. The extension cord passes alternately over a series of fixed and movable pulleys as shown. The fixed pulleys *A* are ordinary porcelain insulators mounted on round-head screws, at the upper end of a panel which should be made of slate or asbestos board. The panel can be attached to the wall in any convenient place. Small cast-lead weights *C* are attached to the movable pulleys *B* to keep the cord taut. The movable pulleys are also made of porcelain insulators, and the connection between the pulley and weight is made from a piece of wire bent to the proper shape.



PARTS AND ASSEMBLY OF ADJUSTABLE EXTENSION LAMP

The lamp cord makes one and a half turns around roller *E* at the bottom of the board and passes out to the lamp. A small spring catch *D* allows the cord to be easily pulled out to the desired length, but prevents it from slipping back. It is obvious that upon pulling out the extension cord the movable pulleys will be lifted, shortening the distance between them and the fixed pulleys. By releasing the catch *D* the cord is allowed to return slowly to its normal position, as shown in the diagram. **M. P. Bertrande.**

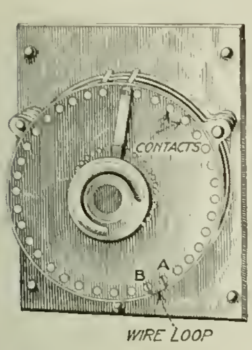
Repairing an Open-Circuit in a Field Rheostat

Repairing open-circuits in field rheostats having the resistance encased in porcelain or other insulating compounds can be accomplished as follows: Assuming that the open-circuit has been located between contacts *A* and *B* in the figure. A radial slot is cut with a hacksaw in the center of each of the two contacts between which the open-circuit is located. Cut these slots about $\frac{1}{16}$ in. deep. Then make a loop of No. 20 B. & S. gage copper wire, as in the figure, and drive it down in the slots. The edges of the slots are slightly upset by a small cape chisel to hold the wire firmly in place, and then soldered to the contacts. All excess of solder is removed so as not to interfere with the contact-arm travel.



FIELD RHEOSTAT

Starting Diesel Engines Under Difficulties

As all Diesel-engine operators know, it is difficult to start these engines when they are cold—that is, below a temperature of 40 deg.—and especially so when they have been exposed to freezing weather for a day or two. The builders usually recommend that they be installed where they can be kept from getting so cold. About the first of November, 1917, I took charge of a plant having two Diesels, in which the engines are under the shelter of a corrugated-iron structure that has been through the vicissitudes of fire and reconstruction and is more of a refrigerating room in winter than anything else.

In addition to the foregoing, the starting-air tanks are a long distance from the engines, and there are ten elbows and bends in the starting-air line. This line is also too small for efficient starting, being of 1-in. double-extra-heavy pipe. The engine is belted to a lineshaft carrying several pulleys and belts, driving the air compressor and circulating pumps and two generators, as well as several other belts that usually are running on loose pulleys, but altogether producing a considerable friction load. And then the engines are old and badly worn in the cylinders so that compression is poor. In fact they were in such shape that the employees of this plant who had been handling them had not been able to start them since last June.

After overhauling and repairing these units as best I could, so that we could get some service out of them before the final shutdown for rebuilding, I started up one without much trouble and continued to do so every day for a week; then the temperature dropped to 19 or 20 deg. above zero and stayed there for several days. On Monday morning I attempted to start up and before quitting had lost all the air that we had stored without getting the engines running. It was then necessary to connect up the steam engine of an ammonia compressor that was belted to the lineshaft and take the belt off the Diesel's pulley so as to drive the air compressor, and pump up the starting tanks again before we got started.

When it was convenient to shut down for a day or two, I cut into the steam line running through the building and connected it into the circulating-water system as near to the cylinder jackets as possible. Now, when it is too cold to start easily, I turn live steam through the water jackets and in ten to fifteen minutes the cylinders are warm enough to start on the first attempt.

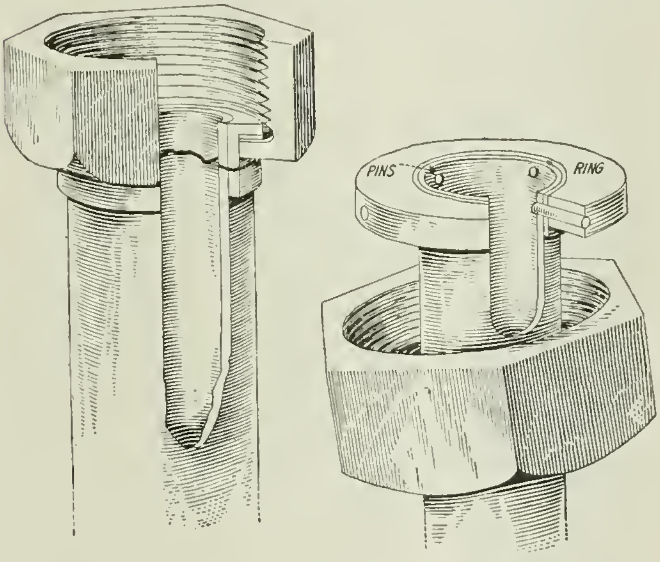
Of course not all Diesel plants are so arranged that they can have steam, and many are so housed that they do not need any external means of warming up, but doubtless there are a good many who might be able to use this method and so get around a serious difficulty.

Austin, Texas. F. C. WILLIAMS.

Repair to Copper Circulating Pipe

The copper pipe connecting the jacket of an oil engine with the radiator broke near a union, as shown by the irregular line in the illustration. It was repaired by the engineer in a short time as follows:

The coupling was separated and a ring was shrunk on the end of the broken pipe and pinned, after which the pipe end was peened, smoothed off and the union put together as before. The pipe when joined was about an inch shorter than originally, but fortunately the radiator could be moved that amount without difficulty. This job seems all the more creditable when it is considered that only a few hand tools were available.



BROKEN UNION REPAIRED

West New York, N. J. LUDWIG V. LAUTHER.

Distinguishing Iron from Steel Pipe

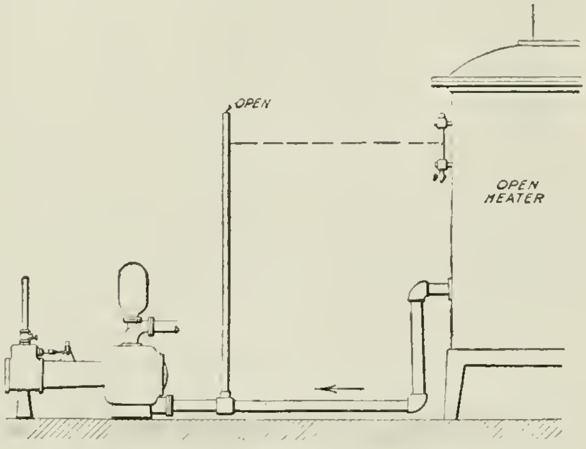
I have noticed several articles in *Power* relating to methods of distinguishing iron pipe from steel, and I herewith present my method, which is very simple.

Aqua fortis (weak nitric acid) applied to the surface of steel produces a black spot; on iron the metal remains clean. By this method the slightest vein of iron or steel can be readily detected. J. W. STANLEY.

Braemar, Tenn.

Vapor Relief on Pump Suction

A feed pump which got water from an open heater situated about four feet above the pump gave trouble by pounding—not only at the pump, but in the discharge line. Various remedies were tried with no success until an air pipe was connected to the suction line with the open end extending above the water level of the heater, as shown in the illustration, after which the trouble ended. **N. C. Gleason.**



OPEN END PIPE CONNECTED TO PUMP SUCTION

Piston Packing Burns Out—No More

My S.O.S. regarding piston packing burning out in the issue of Jan. 22, page 129, brought several fine answers by mail from widely separated places—Staunton, Ill.; Denver, Colo.; Port Huron, Mich.; Trenton, N. J.; and Milford, Mass. I have, of course, replied to these letters, thanking the writers for their interest. Is there any other group of mechanics except engineers who would use their time, stationery and stamps simply to help out a brother engineer who is a perfect stranger to them? One thing that is noticeable about engineers is their unselfish willingness to help others.

Some of the suggestions given me are peculiar, and probably I never would have thought of them. Following, in part, the advice given by two of my correspondents, one suggesting metallic packing and another a certain brand of steam packing, I compromised and used both. Instead of a concave ring in the back of the packing box, I now use a flat one and have made the end of the follower, or gland, flat and use alternate rings of a good high-pressure asbestos rubber packing and rings of plastic metallic packing. Some, no doubt, will raise their hands in horror at such an idea, but the proof of the thing is in the satisfactory results gained.

Another peculiar thing I noticed in the replies received is that the electric men are so certain the fault can be traced to defects in the electric end of the work, while the steam men are just as certain that the trouble is in the steam machinery. However, the steam men were right in this case, so far as I can see in the short time since I made the change. I have tried it severely by drawing the packing tight and also by leaving it loose, but it does not get hot. **James E. Noble.**

Portsmouth, Ont., Canada.

Starting Synchronous Motors

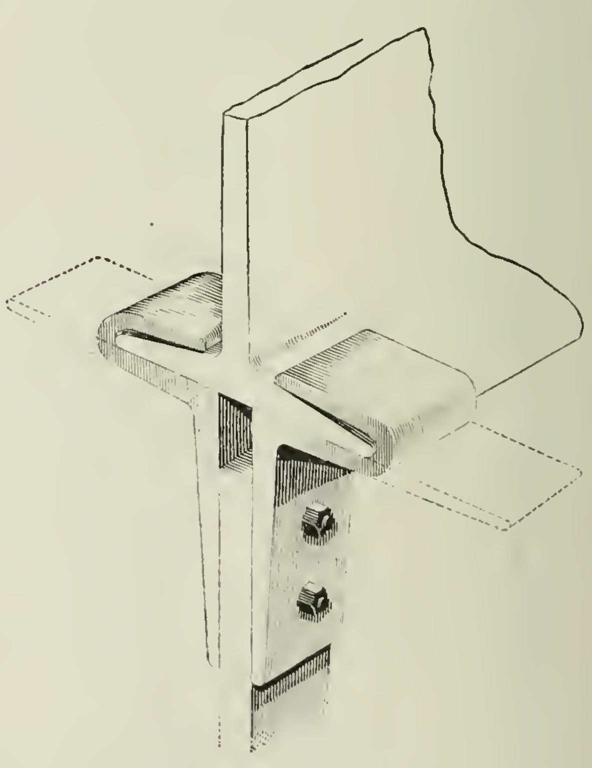
In starting up the synchronous motor in our plant, there is usually one man at the switchboard and another, generally the fireman, at the compensator for starting the motor. At starting, the man at the switchboard closes the oil switch and the attendant at the starting compensator throws the lever to the starting position. When the motor comes up to speed, the man at the switchboard closes the field switch and the attendant at the compensator throws the lever to the running position.

There are times when it is not convenient for the fireman to leave the boiler room in order to help out. It is a case of either waiting or getting someone else. This, again, is often out of the question. To start the motor without an assistant, I first tie the lever on the starting compensator to the starting position, then I go to the switchboard and close the oil switch; when the motor gets up to speed, the field switch is closed; after this I go to the compensator, release the starting lever and throw it to the running position; then I return to the switchboard and make the necessary adjustments. In this way I am able to satisfactorily put the motor into service without the help of an assistant.

Middletown, N. Y. **Thomas M. Gray.**

Hanger-Clamp for I-Beam

The best and strongest kind of an I-beam hanger clamp I know of, can be made from two pieces of 3-in. angle iron sawed off about two inches wide, heated and one end or flange bent back and the other drilled for the strap, as shown. The thickness of the angle is where it is most needed. **W. H. H. Plowman.**



HANGER-CLAMP MADE OF ANGLE IRON

Philadelphia, Penn.

Inquiries of General Interest

Flow of Steam Through 6-In. Pipe—What weight of steam at 150 lb. gage would be delivered per hour by a 6-in. steam pipe 100 ft. long? B. C. W.

The rate of flow would depend on the drop of pressure; that is, the number of pounds per square inch the steam pressure would be reduced in traversing the full length of the pipe. A simple form of diagram for computing the flow of steam in pipes, based on the Babcock formula, with examples, is given on pages 836-7, June 13, 1916, issue of *Power*. For a continuous flow and pressure drop of 5 lb. per sq.in. the discharge would amount to about 9000 lb. of steam per hour.

Diameters of Fire Tubes of Boilers—What is the rule for the diameter of fire tubes of return-tubular and vertical fire-tube boilers? C. H. S.

For natural draft the usual rule is to allow one inch of nominal or outside tube diameter for each 4 ft. of tube length for use with bituminous coal, and for use with anthracite, 1 in. of nominal diameter for each 5 ft. of tube length. For artificial draft the size of tubes may be considerably smaller, according to the force of draft and tendency of the fuel to clog the tubes with soot. For vertical fire-tube boilers, where the course of the heated gases is short and direct, the ratio of tube diameter to length is usually about 1 to 70.

Reason for Lap on Corliss Steam Valves—Why is lap given to the steam valves of single-eccentric Corliss engines? W. R. S.

For obtaining compression of the exhaust the exhaust port must be closed before the piston reaches the end of the stroke. It is not permissible to obtain earlier closing of the exhaust valves by lengthening the exhaust-valve rods, as that would make the valves later in opening and the steam would not be released until after the piston had completed its stroke. Therefore to obtain earlier compression and release, the eccentric is advanced; that is, set ahead of the 90-deg. position. All valve events are thus made earlier, and to delay uncovering of the steam ports by their valves until the beginning of the stroke, it becomes necessary to add lap to the steam valves.

Cushioning of Duplex Pump—How can a duplex pump be given more cushion? H. D. W.

In the ordinary duplex pump, the ports and passages for admission of steam are at the ends of the cylinder, and those for discharge of the exhaust are nearer the middle of the cylinder. The piston in approaching the head covers the exhaust port, while the exhaust edge of the valve is still open and the steam end of the valve covers its port. The volume of steam thus entrapped in the end of the cylinder and steam passage is constant, and there is no convenient means of covering the exhaust port earlier so as to obtain more cushion, excepting to provide a wider piston ring. On pumps of over 10-in. stroke, for regulating the cushion an opening is provided through the partition between the steam and the exhaust passages with a valve inserted for relieving the piston of too much cushion, but cushioning cannot be adjusted to more than the amount obtainable with this valve closed.

Noise in Ends of Cylinder—What causes a noise in a steam-engine cylinder at each reversal of the stroke of the piston? W. E. B.

With a noncondensing Corliss engine, a rattling noise may be due to the exhaust valves being raised from their seats when the steam expands to such a low pressure that the valves are raised from their seats by pressure of the atmosphere. If the noise from this cause continues when the engine is running at regular speed, it can be stopped by throttling or reducing the initial steam pressure, or by joining together the indicator connections of opposite ends of the cylinder with a very small opening. A slapping noise may result from loose-fitting piston rings driven against the sides of the grooves by sudden change in difference of cylinder pressures on opposite sides of the piston, or from frictional resistance to being dragged at each reversal of the stroke. A rattling noise may be due to a broken piston ring or some material out of place, and when it occurs the engine should be stopped as soon as possible and inspected to discover loose or broken parts that might score the cylinder.

Ventilation of Paper-Machine Room—How can a paper-machine room be ventilated to prevent deposit and dripping of condensation from the roof or ceiling? W. H. D.

To retard the condensation it is necessary to keep the roof or ceiling warm. This is best accomplished by sheathing under the roof or ceiling to form a dead-air space and liberally warming the sheathing with steam pipes hung close to its under side and evenly distributed. The space over the machine where vapor rises should be covered with a hood kept clear of vapor by an exhaust fan discharged outside of the room, and for general ventilation of the room to remove moisture, there should be exhaust fans or suction ducts in the side walls, placed at intervals near the roof or ceiling.

Equivalent Evaporation from and at 212 Deg. F.—With an evaporation per pound of coal of 8¼ lb. of feed water at 208 deg. F. into steam at 140 lb. boiler pressure and 96 per cent. dry, what is the equivalent evaporation from and at 212 deg. F.? J. W. N.

Each pound of the feed water contained 208 — 32 = 176 B.t.u. above 32 deg. F. According to Marks and Davis' Steam Tables, a pound of steam at 140 lb. per sq.in. gage, or 155 lb. absolute, contains 332.9 B.t.u. in the water and 861 B.t.u. latent heat; hence with the steam 96 per cent. dry each pound contained 332.9 + (861 × 0.96) = 1159.46 B.t.u. and each pound of the feed water must have received 1159.46 — 176 = 983.46 B.t.u. The evaporation of a pound of feed water from and at 212 deg. F. requires the latent heat of evaporation, or 970.4 B.t.u.; hence the factor of evaporation was 983.46 ÷ 970.4 = 1.0134, and the evaporation was equivalent to 8¼ × 1.0134 = 8.36 lb. of water from and at 212 deg. F. per pound of coal.

Thickness and Weight of Lead Pipe—What is the rule for finding the proper thickness and weight of lead pipe? P. F.

The thickness of lead pipe required to withstand a given pressure may be calculated by the formula,

$$T = \frac{0.433 \times H \times R}{2745}$$

in which

T = Thickness of pipe in fractions of an inch;
H = Head of pressure in feet; (water)
R = Radius of pipe in inches;

from which

$$T = 0.0001578 \times H \times R.$$

For lead a factor of safety of 10 is required, hence for practical application $T = 0.001578 \times H \times R$, or if we take D = the diameter of pipe in inches, instead of the radius, $T = 0.000789 \times H \times D$.

The formula for the weight of lead pipe is:

$$W = 3.86\ (D^2 - d^2)\text{; or } 3.86\ (D + d) \times (D - d)$$

in which

W = Weight of pipe per lineal foot in pounds;
D = External diameter of pipe in inches;
d = Internal diameter of pipe in inches;
3.86 = A constant.

The Coal Problem*

By E. G. BAILEY

THE biggest and most important question before the American people today is the coal problem. Some may disagree and claim that it is transportation. But sift the present situation to the bottom, and you will find that the coal problem, or rather the abnormally high percentage of ash and impurities in the coal, is like sand in the bearings of transportation, of ocean shipping and of practically all industries, causing them to slow down at the most critical time in our history.

Coal is bought solely for the combustible elements it contains. The less ash and impurities in the coal the less number of tons you need. The greater the demand for coal the higher the price and, under present conditions, the poorer its quality. The price has been regulated, but the quality has run riot.

Why have we allowed this to happen just at the time when we need *heat units* in their most concentrated form? Why are the railroads burdened today with hauling millions of tons of utterly worthless dirt? To say that this excess of impurities in the coal coming on the market today is worthless does not describe the situation. The price paid for this dirt is only a small fraction of the damage. The rest of its cost is in the decreased efficiency, the lowered capacity, the increased labor and the excessive repair bills involved in the combustion of this coal—and in the necessity of closing down industries because of the lack of coal which might have been shipped in place of these so-called "worthless," but really exceedingly costly, impurities.

Impurities in Coal

Through the past winter we have heard a great deal of talk about the deterioration in the quality of coal, the increase of ash, slate, sulphur and other impurities. We know this has occurred, but let us see how much it has amounted to, how much it has cost, and we can decide better what efforts should be put forth to remedy this difficulty.

We find from reliable sources that the coal received in many of the largest power plants in the country has increased by 5 per cent. to 10 per cent. in ash and has decreased in heating value by 8 per cent. to 12 per cent. Many good authorities state that the amount of coal consumed in their plants has increased 10 per cent., entirely owing to the inferior quality of coal received today as compared with that received previous to 1916. Figures from a prominent manufacturer who has received coal from the same district during the past seven years and has followed its quality closely by analysis and other means show a decrease of 9 per cent. in B.t.u. during the calendar year 1917 as compared with the average of five years, 1911 to 1915 inclusive.

War conditions should be borne in mind in this connection. We should not assume that the quality of all coal mined has decreased in this same ratio, for the Navy and other Government requirements have increased by several million tons, and they rightfully are getting the better coal. Hence, some of the decrease in the quality of coal going to industrial plants and locomotives has been due to confining their supply to the mines of inferior quality. But evidence is at hand to show that coal coming from the same mines carries a much higher percentage of bone, slate and free impurities than it formerly did, and as a conservative estimate I am confident that the increased coal consumption of this country during the year 1917 due to the inferior quality resulting from neglect of preparation at the mines, tipples and breakers amounted to at least 5 per cent. In other words, of the approximately 600,000,000 tons of coal produced and shipped to market during the last year 30,000,000 tons was worthless dirt, slate and rock.

How much has this increase in impurities in coal cost the United States during the last year? In the first place coal has been worth on an average, counting contracts and all, about $2.50 at the mines. The average freight, including both rail and vessel, paid on all coal produced is probably in the neighborhood of $1.50 per ton. So that the 30,000,000 tons of dirt which has been delivered to the consumer has cost about $120,000,000 during the past year.

But this only takes into consideration the cost of the coal delivered to his plant. He then has the additional cost of firing this inferior coal, repairing furnaces, stokers, locomotives and the cost of handling the ashes. These items would add a few million dollars more, but that is a mere bagatelle compared with the cost due to the shortage of coal, the closing of plants and our heatless holidays. Estimates by various authorities on the cost of the heatless holidays range from one billion dollars on up, and that was probably, for the time being, the best and cheapest way out of the difficulty.

Coal Shortage or Dirt

We have been talking about the coal shortage, while in reality we have been loading our cars and locomotives with slate and impurities instead of coal, and had coal of the former quality been shipped to market, we would have had 30,000,000 tons more real coal than we did get.

The effect of this increase in the percentage of ash has been cumulative. Storage piles have been gradually exhausted, and the supply to consumers has diminished to absolutely nothing in many cases, due to each day's coal consumption requiring 5 per cent. more than it otherwise would, because of the high percentage of ash alone, regardless of weather conditions or increased load. Suppose that all of the slate and impurities corresponding to this 5 per cent. increase had been concentrated into two or three weeks of normal shipments during the middle of the winter and this 30,000,000 tons of pure slate and rock were loaded into 1,000,000 railroad cars without any coal mixed with it. Every American citizen would have been up in arms in a minute, and indignation societies and vigilance committees would have emptied the slate out along the railroad tracks and started the empty cars back to the mines to be loaded with coal instead of impurities. But the final result has been the same.

We should also remember that the inferior quality of coal, in addition to tying up 1,000,000 railroad cars and requiring the use of thousands of locomotives, has also seriously affected the operation of the locomotive itself. The locomotive is a complete power plant, with grate area, size of nozzle, draft, steam consumption, etc., very nicely balanced. If either the quality or character of coal is changed on a locomotive, its efficiency and capacity are affected. Today locomotives are receiving, not only the poorer quality of fuel, but coal of widely varying character due to the allotment of railroad fuel to all mines. This has resulted in greatly reducing the hauling capacity of the locomotives.

In buying coal we have been so accustomed to expect the quality to decrease when the price went up that we considered it inevitable. We thought there was no remedy. The coal operator has not been wholly to blame, because he could not control the preparation of coal at the mines of his competitors. If he was conscientious and prepared his coal, he was the loser and the man who shipped dirty coal to the market obtained his profits.

The cause for this condition is well known to anyone at all familiar with the mining of coal; the reason is that the technically trained men of this country have failed to master a difficult problem they tackled several years ago and would have mastered by this time, had they had the courage of their convictions and the ability to handle human-nature problems as well as engineering.

In mining coal we find the ash occurs in two general forms, intrinsic ash and extraneous or free impurities. The intrinsic ash is locked up in the coal, so to speak, and is inseparable from it. The purest lump of coal contains a percentage of ash that is thoroughly mixed through it, much like the ash in wood. From any one coal seam in a district this intrinsic ash usually runs fairly uniform, although it may vary widely in different coal seams, in different districts, or even in different strata of the same seam.

---

*Lecture (somewhat condensed) delivered at the Johns Hopkins University, Baltimore, Md., Feb. 27, 1918, as one of the J. E. Aldred Lectures on Engineering Practice.

The extraneous or free impurities usually consist of slate, shale or sand rock from the roof of the mine, and clay from the floor, and sometimes slate, shale and sulphur balls are sandwiched between the coal strata. The slate and shale strata in the coal seam itself are the most difficult to eliminate because they are more or less broken and intermingled with the coal when it is shot down and require extra labor and special care on the part of the miner to throw back these impurities or load them separately into mine cars for the dump. Small sulphur balls are still harder to detect because they are usually covered with coal. Large ones should be detected by their weight. The amount of free impurities likely to come from the roof varies widely with its character. Some mines have a very firm roof that seldom breaks, while in others it crumbles and falls badly, mixing in with the freshly mined coal much like the strata of slate running through the seam. There is little excuse for loading dirt from the floor of any mine. Sometimes the fireclay bottom is very soft, making it difficult to prevent its being shoveled up with the coal, and again the mining-machine operators may carelessly permit some of the bottom to become mixed with the slack or fine coal.

There is another form of impurity generally known as "bone." This is really a stratum of coal containing an abnormally high percentage of intrinsic ash. The ash in bone coal usually runs about 30 per cent., although it may be much higher or even lower. As there is no distinct division between coal and bone, there is often a difference of opinion as to what should be loaded as marketable coal.

How Coal Is Usually Cleaned

In normal times there is a great deal of real competition between different mine operators, in selling soft coal, at least. In meeting this competition the operator is forced either to sell at a lower price or produce a superior quality of coal. He, therefore, puts forth considerable effort and goes to extra expense to produce as low-ash coal as possible. This preparation of the coal is accomplished by compelling the miner to throw out all free slate, bone and other impurities previously mentioned. Inspectors examine the conditions of the mine—which, by the way, may vary a great deal in different parts of the mine as it develops—and they instruct the miner just what to load out as coal and what to throw back in the gob as refuse or load out separately for the slate dump. Additional cleaning of the coal is done on the railroad cars as each mine car is dumped, and during the last ten years many mines have been equipped with picking tables. In many districts the slack and smaller sizes of coal have the extraneous or free impurities removed by washing. At anthracite mines the slate and bone are picked out of the larger sizes in the breakers and removed from the smaller sizes by washing.

In all cases the preparation and cleaning of coal increases the cost to the operator, both for labor and equipment as well as the actual tonnage of impurities and some accompanying coal that is removed. The customer has been glad to pay more for the cleaner coal because it saved his paying the freight on slate and impurities.

In times of normal condition in the coal trade, which existed between the years of 1903 and 1916, competition carried the preparation of coal so far that a great deal of really marketable coal was thrown aside or left in the roof or floor of the mine, merely because it contained a slightly higher intrinsic ash than the remainder of the seam. Oftentimes this amounted to as much as 10 to 20 per cent. of the total coal in the seam, while its elimination reduced the ash content in the coal as shipped by only 1 or 2 per cent. This is one of the extravagant wastes which has taken place, and which has been so frequently referred to by the Bureau of Mines in support of its estimate that 50 per cent. of our coal resources was wasted beyond recovery in the mining. Another big waste of our coal supply has been due to mutilation of the thinner seams or those having a higher ash content, by first mining the thicker and better seams underneath.

There was an increased demand for coal in 1916. Naturally, prices began to soar, and many consumers foresaw what was coming and were glad to pay any price in order to get coal and fill up their storage space. This condition continued through the winter of 1916-17 until it was of common occurrence to pay as high as $5 and $6 per ton for bituminous coal at the mines. Most of the purchasers were so anxious to get coal that they forgot all about quality and were willing to take anything at any price, in order to keep their plants in operation.

It is only logical, under such conditions, for the mine operator to ease up on the preparation of coal at the mines. He has ample market at a high price for every ton of coal that he can load.

Some may think that the price of coal at the mines as fixed by the Government in August, 1917, being lower than the operators considered justifiable, had something to do with the decrease in quality. It may possibly have affected the preparation of coal in a few instances where the operator was forced to reduce his costs as much as possible, but if the Government price were advanced on the present basis of control to $5 per ton at the mines, it would not reduce the percentage of impurities in the coal one iota.

At the time when we should have given attention to conservation of our natural resources, we were wasting large quantities of really marketable coal. But in a crisis like the present war, when we need large quantities of coal in its purest form with the most concentrated heat units, we find the miners are loading all of the high-ash coal, bone and in many cases, slate, rock and sulphur balls with practically no effort on the part of the operator to stop them. In fact, most of the picking tables and coal washers have been discontinued and the entire product of coal with its impurities goes to market unchecked. In some cases the operator is loading the gob pile, the culm bank, coal from the poorer parts of his mine, or is concentrating his production on the mines of poorest quality, for he knows that under present conditions anything will go, and he is reserving the better quality of coal for future needs when strong competition is resumed.

There has been a time, and there will again come a time, when conservation of our coal supply should be carefully considered in connection with the preparation of coal for a competing market, but now is not the time to conserve our national resources. Today, when every ounce of heat energy, every railroad car and every locomotive should be producing maximum results, one thing above all others should claim the attention of the men of this country, and that is to distribute coal in its purest form to the consumer and obtain maximum efficiency in its combustion. Instead of doing that, we are clogging our railroads and furnaces with the dirtiest and poorest quality of coal ever produced.

What Is the Remedy?

To simply appeal to the coal operators and miners on the grounds of patriotism will not accomplish the results. We must go to the very root of the matter, and during the present crisis eliminate every possible pound of slate and impurity from the coal as it is loaded into the railroad cars at the mines. This will be equivalent to increasing the motive power, the car supply and terminal facilities of our railroads to the extent of 30,000,000 tons carrying capacity per year. It is possible; it can be done; and it *must* be done. The question remains how to do it most quickly and at least expense.

You must bear in mind that increasing the price alone will *not* improve the quality, and without the quality being improved the railroads cannot haul the necessary heat units. There is enough labor available at the mines to clean the coal; our trouble is due to lack of railroad facilities to haul the excessive amount of impurities it contains. It seems so perfectly self-evident that we must put forth every effort to concentrate as many heat units in each ton of coal which our railroads can handle, that in the face of these figures we can go to any end in carrying out the remedy. This question is important enough to do the job right and anything which is worth while *can be done*.

Pay Price in Proportion to Quality

I would recommend that the Government establish coal-sampling stations at certain points where large numbers of railroad cars are unloaded to vessels or power houses. These sampling stations should be equipped with the necessary machinery for handling samples of one thousand pounds or more so that the sample will be thoroughly representative of the individual car from which it is taken. From this sample determine the percentage of total ash as well as the free impurities (slate, rock, etc.) so that a positive check will be obtained on each mine as to the quality of coal being produced, and the effectiveness of its preparation.

By locating these sampling plants at such points as New York, Philadelphia, Baltimore, Hampton Roads, Cincinnati, Lorain, Buffalo and other lake loading ports, adding Chicago, St. Louis, Indianapolis, Birmingham and other cities throughout the United States later on as the work is extended, coal from every mine in the adjacent districts can be consigned or reconsigned by the Fuel Administration to these cities and to these particular piers and power plants so that at least one sample each month will be obtained from every mine shipping coal. Later on as the system is perfected it could be increased to the sampling of one car out of every ten shipped, so that a very fair average of the quality of coal loaded from each mine would be obtained. Even though not enough cars could be sampled to get an average that would be scientifically accurate to a fraction of one per cent., the influence on the operator and miner would be effective.

To give the coal operator a real incentive to clean his coal as he should, the price he receives should be materially affected by the quality of coal produced. It would be advisable to go a step farther and base the distribution of cars to the mines on quality also. The quality as shown by the results of one month should form the basis of price and car distribution for the subsequent month, so that no confusion resulting from back charges and adjustments need interfere with the plan.

The adjustment of price for variations in intrinsic ash should be nominal, say 5 or 10c. per ton, but for extraneous ash it must be severe, such as 25 to 50c. per ton for each 1 per cent. ash.

The base price for standard quality of coal should be established by the Government as at present, with possibly different base prices and different quality standards for the several districts, taking into account the character of coal, height of seam and other mining conditions, but the main thing to strive for is to obtain the highest quality of coal and the most concentrated form of heat units in order to tide us over the coming year, which is going to be much more critical than that just past, unless some radical step is taken to apply a remedy for the basic cause of the present situation.

This work of sampling and accurate quality determination should be supplemented with Government inspection at the mines to prevent the loading of bad crop coal and to keep in first-hand touch with the mining conditions as a supplemental check upon the preparation of coal and to instill a spirit of coöperation.

Real knowledge of the quality of coal being produced will also be of great benefit in classifying coal from various mines into the different pools so the consumer, and particularly the railroads, will receive coal of uniform quality, thereby enabling them to obtain maximum capacity and efficiency from the coal they use.

The Remedy Is Feasible

There may be some people pessimistic enough to say that this scheme cannot be carried out, it would cost too much money or we cannot get the men to do it; but this question is of such basic importance today that some remedy is absolutely necessary. We have our choice of either building thousands of locomotives, a hundred thousand railroad cars and adding to the terminal facilities of our railroads within the next few months to haul this 30,000,000 or more tons of dirt, or asking the railroads to ship only the most concentrated form of heat units in coal of highest quality.

The latter can be done, the remedy is feasible and practical, it can be started immediately and put into effective operation within a few months at a trivial cost as compared with any other remedy available. The Government already has departments familiar with every problem which enters into the carrying out of this scheme. It would require many competent technical men to carry it out, such men as you, who are being turned out of our colleges and universities today, and those who have preceded you during the past few years.

In normal times, when competition was strong, the consumer could get about what he wanted at a very low price, but now in his anxiety to get coal he has catered to the coal man, forgotten quality, paid any price, and has been satisfied to take whatever the coal man gave. Today we hear more talk of quality from the coal operators, who want the quality considered as a basis of price, as a basis of car distribution, as a basis of classifying coal into different pools, than we have heard from the consumer. But the operators seem to think that it is sufficient to classify the coal very roughly, using quality data obtained prior to present conditions. This would help some, but it is not the real remedy that must be put into effect today, for it must be based on the quality of coal *now* being produced.

The engineers of this country, who are responsible for efficiency in the combustion of coal, should also make a very thorough search into the actual conditions which exist in the plants under their care. One of the difficulties is that combustion has been discussed and rehashed so many times and they have been warned about excess air, unburned gas, CO_2 and various other things until it is a good deal like the boy and the wolf. They know so well what ought to be done that they begin to think they are actually doing it. Others know they have done it once and assume that the men in their plant are continuing to do it without constant supervision or checking up, but everyone who is at all familiar with the combustion of coal knows that there is room for decided improvement along this line in a majority of power plants, including many of the larger central stations in operation today.

One of the basic difficulties is, the person responsible for the operation of the plant does not always know exactly what results he is getting. If he is basing the results on coal per kilowatt, coal per unit product, such as steel, paper, cloth, etc., or even pounds of water evaporated per pound of coal, he does not have as close a check upon his efficiency as he should have, because he is likely to blame poor results to the inferior quality and varying character of the coal he has received. To a large extent the coal has been responsible. The decrease in quality has taken his heart out of his work so far as striving for high efficiency is concerned, and I have even heard some prominent engineers make the remark that they did not care a rap about efficiency—what they wanted was coal that would give them capacity. They apparently forgot that when they are getting efficiency they are also getting capacity, for wasted heat units can accomplish nothing. Efficiency and total plant capacity go hand in hand. We must stretch every ton of coal out to last as long as possible.

Let us forget for a minute much of the detailed theory and ideas of combustion and come down to a few basic facts. Coal is fired to the boiler furnaces to produce heat. Whatever the heating value of this coal may be, whether it is 10,000 or 14,000 B.t.u. per pound, that figure represents 100 per cent. of the heat units available for making steam in that boiler. The problem is to transfer as many heat units as possible from the coal to the steam. All of this heat cannot be utilized, but it does all show up some place, and the channels through which this heat passes may be divided into three general classes:

		Best Practice, Per Cent.	Probable Average, Per Cent.
1	Incomplete combustion (loss)	2	7
2	Heating up flue gases and other things beside water in in boiler (loss)	18	28
3	Evaporating water in the boiler (useful)	80	65
	Total heat in coal as fired.	100	100

The entire 100 per cent. of heat, no more and no less, always shows up in these three main items, which may be called a heat balance.

The amount of heat in the third item represents boiler efficiency, and it must be low if the other two items are high and it can be high only by keeping the other items low. These two loss items are such that they get first chance, so to speak, at the heat units in the coal, and high boiler efficiency can be assured only by knowing what are these controllable losses and how to keep them at a minimum.

The first item, incomplete combustion, covers unburned coal and coke carried away in the ashes. This is a loss that can readily be observed by inspection and checked up by sampling the ashes and determining the percentage of combustible. The other loss under this item is unburned gas, principally carbon monoxide (CO), which is due to carrying too thick a fire and operating the furnace like a gas producer. This loss can be obviated by carrying a thinner fire and providing a greater supply of air per pound of combustible. If this is carried to an extreme, too much air passes through the furnace and carries away large quantities of heat at flue-gas temperature, thereby increasing a loss which would come under the second item. It is, therefore, necessary for the fireman to have some guide in maintaining the fuel bed in the proper condition so as to obviate the unburned-gas loss on the one hand and the excess-air loss on the other.

The most usual means of checking up this condition has been flue-gas analysis, and engineers should apply their knowledge of this subject to actual practice today as never before. There are other means that serve as a very valuable guide, such as the relation between the rate at which air is supplied for combustion and the rate at which steam is generated from this combustion. This is based on the fact that air is a fuel just as much as coal, and a certain evaporation should be obtained per pound of air. This is practically independent of the quality or character of fuel.

WATCH THE APPEARANCE OF THE FLAME

Another method, which is within the reach of every fireman and every engineer in the country without buying a cent's worth of equipment, is to watch the appearance of the flame from the furnace. The critical points to watch are the top of the first pass in a cross-baffled water-tube boiler; the point where the gases enter the tubes at the rear of a return-tubular boiler, or the corresponding location in boilers of other types. When there is too little air for complete combustion a flame of burning CO gas is visible at these points. Oftentimes it reaches entirely through the boiler and escapes before combustion is complete. A large loss due to unburned gas may result even though this flame may extend only part way through the tubes of a return-tubular boiler, or only start down through the second pass of a water-tube boiler, for the gases are cooled below their ignition temperature before combustion is complete. On the other hand, if too much air is supplied to the furnace, observations at these points will show no flame at all. The most efficient conditions exist when there is a good mellow flame ending at about these points in the gas passage. This shows that there is air enough for complete combustion, but not much loss due to excess air. The latter loss may be very great when the flame is too short. In many metallurgical furnaces the appearance of the flame is the principal guide in controlling combustion.

At the same time that the engineer and fireman are looking into the gas passages of their boiler, studying the appearance of the flame, many of them will be surprised to find how dirty are the tubes and how many holes there are in the baffles of their water-tube boilers. These conditions are much more prevalent, even in the largest power plants, than is generally supposed or admitted. Both conditions result in a high temperature of gases escaping from the boiler and materially increase the loss in the second item previously mentioned. It pays big to keep boiler tubes clean and maintain baffles in good repair, even when coal is at normal price and there is plenty to be had; but now it is a crime to overlook conditions that can be so easily remedied and produce returns of such magnitude and importance.

KNOWLEDGE AND ETERNAL VIGILANCE

In connection with the operation of power plants there are two old quotations that exactly fit, and I urge everyone to bear them in mind in connection with their own plant. The first one, "Knowledge is power," is certainly applicable. You *must know* what your plant is doing, you must know what is the efficiency of your boilers and furnaces, what and how much your losses are before intelligent steps can be taken to apply remedies. If you simply know that the efficiency is poor, you cannot improve it until you know why it is poor. If there are big losses in the first item of the heat balance mentioned, you should do one thing. If they are in the second item, you should apply some other remedy.

The other quotation, "Eternal vigilance is the price of economy," is equally pertinent. Many people have spent much time and money making an extensive series of tests in their power plants, and by means of such tests obtained very good evaporation and high efficiencies which pleased them greatly. The results were tabulated for blueprints or framed in their office, and many of them are foolish enough to think that their plant is still producing this kind of results. Some of them are, and some of them are getting even better results today than they were during such tests, but this applies only to those who are using eternal vigilance and checking up their efficiencies as well as their losses from day to day and hour to hour. As George Diman says, "A boiler test is a good deal like a horse race—you can get most anything you want out of it, but you keep on burning coal 365 days of the year."

IMPORTANCE OF THE COAL INDUSTRY

The things which have happened during the last year in connection with the coal industry have served to waken the engineers as well as the general public to the importance and magnitude of the coal problem. It not only needs the most careful attention and the most diligent study today, but it needs the continued service of the technically trained men of this country to follow it up in the future, for it always will be a problem of the greatest magnitude in the United States. We have been bountifully supplied with hundreds of thousands of acres of coal of good quality; we have been mining it so cheaply and thinking so little of the future that most people have not realized what tremendous problems were involved and how important they were to the industrial and physical welfare of the country.

One of the most important problems is the relation between the price and value of coal. This has not yet been satisfactorily or equitably determined, for it involves a third factor—conservation of our natural resources which should enter into this relation, and the working out of this phase of the coal problem alone will require a great deal of attention by the best brains of the country.

Another illustration of a single phase of the coal problem which is deserving of further attention is the simple question of storage. This always has been a serious problem, especially for certain coals when stored in certain parts of the country. Following the war it is going to be more so, because people who have been handicapped now are going to store larger quantities of coal as soon as they are able to get coal to store, but what is the use of storing if they are unable to prevent expensive losses due to spontaneous combustion?

I therefore urge you students of the Johns Hopkins University and young men from other schools to give the coal problem in its various phases your most earnest consideration in selecting your life work or at least your first job, because there is no more important problem today, and there is no richer field for the future, than to tackle some phase of this important industry and bring to light and establish as facts many of the traditions that have been drifting along for so many years without knowledge as to their control and application in normal times, or even in emergencies like that of the present day.

The problems that concern us most are those of the immediate future. Are we going to have coal enough to see us through the coming winter? The present indications are that unless some radical steps are taken immediately, the coal shortage will be much worse than it has been. To be satisfied with preferential shipments and permit many of our basic industries to close down is to be a quitter, when by concentrating our efforts on loading clean coal at the mines and improving the efficiency of its combustion in furnaces we can have ample coal for all, thereby helping instead of hindering the Thrift Campaign.

We have heard the argument that we should be patriotic and be content with inferior coal, old culm banks and other refuse fuel the same as we are with wheat substitutes in our bread. But the food and fuel problems are very different. Economy in their use applies equally to both, but the neck of the bottle of the food question is production, while the weakest link of the coal problem is transportation. It is a crime to burden our railroads with hauling dirt when it is within our power to ship clean coal and supply heat units in their most concentrated form.

Boiler Explosion at East Chicago Kills Seven

At 10:15 p.m., on Feb. 18, a most unfortunate boiler explosion occurred at the Inland works of the Republic Iron and Steel Co., East Chicago, Ind. A total of 43 men were victims of the accident. Two were killed instantly, two died in the hospital soon after, and in the course of a few days three more succumbed to their injuries. Of the others ten were wounded seriously. At the time of writing they were still in the hospital but on the road to recovery. The remainder, for the most part, received minor injuries requiring only first-aid dressing. As an explanation of the excessive casualty list, it may be stated that at the time of the accident a number of men were sitting in their favorite gathering place in the vicinity of the boiler, eating lunch. Near-by, others were transferring a truckload of material from the mills. Scalding from hot water issuing from a broken feed line on an adjacent boiler and flying brick from the setting of the ruptured boiler were the sources of injury.

The boiler was of the Cook vertical water-tube type, rated at 250 hp. It had been installed in 1901 as a waste-heat boiler, taking the gases from a furnace serving a 16-in. bar mill. With a similar outfit it occupied a sheet-steel building measuring 65 x 140 ft. About three years ago the two furnaces were removed, but the boilers were retained, equipped with dutch-oven furnaces provided with hand-fired grates and used as auxiliary units to help out with steam on large orders and to furnish a necessary supply on Sundays, holidays and at times when the furnaces and their respective waste-heat boilers were down. In other words, the boilers were subject to intermittent service, being fired up and allowed to cool off frequently in the course of a month.

Including the two auxiliary boilers just mentioned, the plant contained a total of 18 vertical water-tube boilers, 11 rated at 125 hp. and 7 having double this capacity. As previously intimated, 16 are waste-heat boilers, each being located in proximity to its respective furnace. All feed into a common steam line supplying the engines of the mill. The pressure on this line, depending upon the number of furnaces and waste-heat boilers in service, the condition of each and the demand of the engines, varies from 70 to 125 lb., the latter pressure being the maximum allowed for safe operation. A chart from a recording gage on the steam line showed that the pressure had run through this range on Monday, the day of the accident. At the time of the explosion seven boilers were in service and the pressure on the line was 70 lb. The ruptured boiler had been cut out of service Saturday on account of two leaky tubes. These tubes had been replaced on Sunday, and the boiler filled with water. One hour before the explosion the boiler had been fired up cold, and within this period the pressure had built up to 50 lb. Both the engineer in charge and the water tender had looked at the gage just before the explosion, as they were intending to "cut in" the boiler on the line when the pressures equalized.

Without any preliminary indication the boiler exploded, the brick walls of the setting spreading out and the top drum with the tubes rising through the roof and landing about 50 ft. distant on the side opposite from the furnace. The roof was damaged badly and the whole side of the building blown out, the property loss approximating $20,000. The lower drum and the tube sheet remained on the foundation.

The steel stack connecting with the boiler through a cone-shaped breeching, was propelled 75 ft. in the opposite direction. The guy wires apparently turned it top down, and in this position it cut through a box-car half filled with firebrick, coming to rest on an axle of one of the end trucks and remaining in that position as shown in the general view. The boiler steam pipe was ruptured between the valve and the main steam line, and a length was broken out of the latter, so that steam from the other boilers rushed out of the ruptured ends. Within three minutes the pressure was down on the whole plant, but before the other boilers could be emptied completely, hand-operated valves in the line beyond the ruptured points were closed. With the line located about 40 ft. above the floor and the building open, it is felt that steam issuing from the header did not contribute to the suffering of the injured. Those scalded were in line with a stream of hot water forced from an adjacent boiler and this was the cause of at least half the injuries. A 2½-in. feed pipe leading into the bottom drum of this boiler had been ruptured by the explosion.

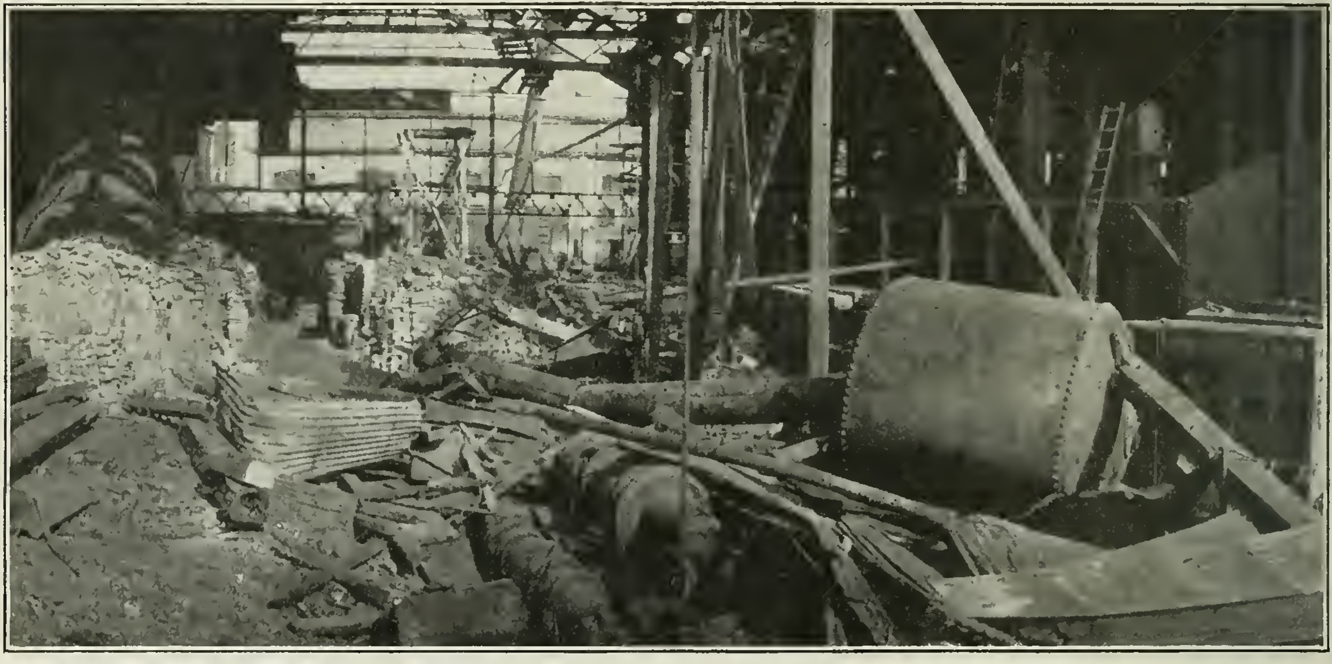


FIG. 1 GENERAL VIEW OF WRECKED BUILDING; STACK STICKING IN BOX-CAR IN BACKGROUND

As the Cook boiler, formerly built by the McNeil Boiler Co., of Akron, Ohio, is no longer made, it may be well to review its construction. The boiler under discussion consisted of an upper steam drum and a lower mud drum connected by a 14-in. central flue and 120 No. 10 gage seamless Shelby tubes 4 in. in diameter and 20 ft. long. The tubes extended through the sheets and were rolled and belled to make tight joints. The drums were 80 in. in diameter, the top drum being 7 ft. deep and the lower drum 44 in. The vertical seam was double-butt-strapped triple-riveted, having a computed efficiency of 85.8 per cent. The metal of the crowned heads was ⅞ in. thick, the shell plates ⅝ in. and the tube sheets ¾ in. At either end the central flue was riveted to a flanged portion of the tube sheet, turning into the drum in each case. In addition eight 1¼-in. round stays tie the flue to the crowned head of the steam drum and six 2½ x ½-in. flat braces secure it to the lower head. The tube sheets were also tied to the heads by evenly spaced 2 x ½-in. double-strap stays, six having been placed in the upper drum and eight in the mud drum.

FIG. 2. LOWER DRUM, SHOWING THE RAISED TUBE SHEET

In this particular boiler water was fed into the steam drum. The circulation was down through the central flue and up through the tubes. The gases from the furnace made one pass along the tubes and around the upper drum into the conical outlet to the stack. The boiler had a full brick setting. It was equipped with two 3½-in. pop safety valves in good working order. Manholes in both drums were provided to afford access for inspection and repairs. From the outside it is difficult to inspect the central flue. A subsequent inspection of this part of a duplicate boiler required the cutting away of 20 tubes.

An inspection of the damaged boiler revealed no defect in the top drum or in the tubes. The stays in this drum were twisted, and one of them had been broken as a result of the explosion. The central flue was intact, but had been buckled slightly near the center, a natural result if the bottom of the flue first struck the ground. In the lower drum the central flanged portion of the tube sheet had been torn off and the sheet pulled up at the center to form a convex surface having about the same radius as the head of the drum. The joint attaching the sheet to the circular wall of the drum held fast. All the stays were broken. In four of the flue braces the crowfeet at the bottom were ruptured. In the other two the break was near the top of the stay, the riveted end remaining intact in each case. With one exception the flat double stays supporting the tube sheet broke at the top.

Nearly all the breaks in these stays gave evidence of some crystallization, but not sufficient to materially lessen the strength. Notwithstanding the long service there was no evidence of corrosion in the boiler. The metal was clean and free of scale. Two years previously, the boiler had been entirely retubed and 20 new tubes had been put in place Christmas week. On Jan. 20 an insurance inspection revealed no defects. Cracks or any visible cause of weakness would probably have been discovered at that time. On account of coal shortage the boiler had not been fired more than ten times since the inspection.

A review of the case would indicate that the initial rupture occurred at the knuckle of the central flange of the lower tube sheet. As will be remembered, this was broken away and could not be found after the explosion. The 21 rivets of $\frac{13}{16}$-in. diameter holding it to the flue were greatly elongated, in some cases the reduction in area being 75 per cent. The conditions under which the boiler operated were favorable to induce failure at this point. As previously stated, the boiler was in irregular service, being fired up and cooled off frequently. Before the explosion it is evident that the boiler must have been forced to raise a pressure of 50 lb. from cold water in one hour. For a boiler of this type three or four hours would have been better. With no baffle to guide the flame, the intense heat from the furnace would strike the tubes on the furnace side and the front of the central flue, leaving the other half of the flue and the rear tubes comparatively cold until proper circulation had been established. This would create expansion on the furnace side of the boiler and tend to tilt it away from the fire. In a boiler of this type after being used for a short time, the tubes will warp to a certain extent and will have little holding power until straightened out. Consequently much of the stress would be thrown on the central flue and with the tilting action previously mentioned the strain on the lower flange would be particularly severe, tending to weaken and crystallize the metal in the flange. It is quite probable that during the hard firing a crack developed at the knuckle of the flange on the furnace side and followed around until the metal weakened enough to let go. This would release the pressure, the water in the

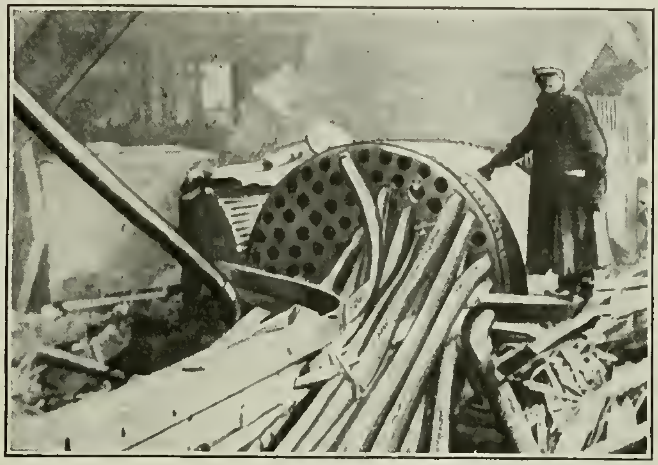

FIG. 3. UPPER DRUM AND TUBES SHORTLY AFTER THE EXPLOSION

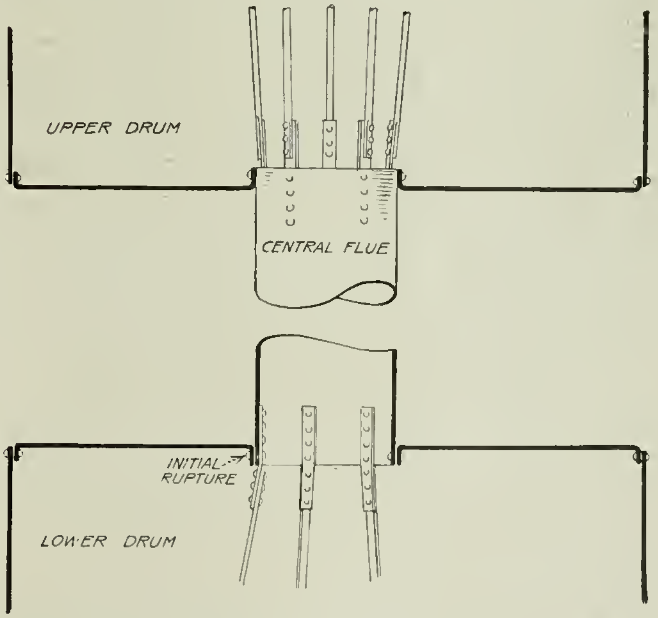

FIG. 4. VERTICAL SECTION THROUGH BOILER, SHOWING FLUE BRACING AND POINT OF INITIAL RUPTURE

boiler would flash into steam and in rushing down the central flue would produce a skyrocket effect that would be irresistible. Coming suddenly, this force snapped all of the lower stays, pulled the tubes out of the sheet and, in doing so, raised the sheet itself as previously described, the upper drum and tubes shooting upward and landing some 50 ft. away.

Other theories have been advanced. For example, the unequal expansion might have snapped the tube-sheet braces on the furnace side and so weakened the holding power that the explosion resulted. The boiler in this case would have been propelled away from the furnace, and this is the direction in which it did go. The evidence, however, favors the theory first advanced, and if this is correct, the central flue was an undesirable element in the boiler design. It appropriated much of the stress created by expansion, acted as a powerful lever on the [illegible]nge and centered the holding power in one element rather than in the 120 tubes of the boilers.

Chicago Section A. S. M. E. Discusses Coal Situation

On Mar. 1 at the La Salle Hotel, the Chicago Section of the American Society of Mechanical Engineers held its second dinner meeting of the season. The topic was "The Coal Situation." Prof. H. H. Stoek, head of the Mining Department, University of Illinois, and chairman of the Conservation Committee of the Fuel Administration for Illinois, and Joseph Harrington, also a member of the committee, were the speakers. Prof. A. N. Talbot, the newly elected president of the American Society of Civil Engineers, was present and in response to an invitation from the chairman made a few remarks upon the present need for coöperation among engineers. The recent decision of the civil engineers to take quartrs in the Engineering Societies' Building, he said, was a step in advance and it was his opinion that it would result in close and united effort of the various engineering bodies.

Joseph Harrington, who was called upon to open the topic of the evening, said that it was not his object to reiterate the familiar phrases in regard to the character and extent of heat losses, assuming that the body of engineers present were familiar with these details. With engineers of experience it is not so much a question of what constitutes efficiency or wherein the losses occur, as it is to apply the knowledge of efficiency measures from both the physical and the human viewpoint. The efficiency of a boiler plant depends on the inherent efficiency of the equipment and the efficiency of the operatives in using this equipment.

Mr. Harrington contended strongly that efficient apparatus must be provided. While intelligent operation serves to overcome to a certain extent the deficiencies of the equipment, it is not adequate to offset old worn-out inefficient apparatus, and it is a matter of mathematics to demonstrate the wisdom of scrapping old equipment and providing modern machinery in its place. As to the efficiency of operation, this depends on the intelligence and interest of the operating force. These, in turn, must be supplemented by adequate instruments and a general record of observations. Granting that all of the foregoing is understood and applicable in such instances where both the will and the money are available, the question still remains, how to apply this knowledge in the universal manner necessary to have any practical effect on the coal consumption of the entire country.

Two general methods appear—the educational, or patriotic, and the autocratic, or compulsory. The former method is that which is now being attempted by the conservation department of the Fuel Administration, and in spite of every effort it is almost impossible to reach all coal consumers. It would mean the education of millions, and the outlook is more or less discouraging to those who see the necessity of conservation for the immediate future. This method, however, is necessary and satisfactory as far as it goes. It is applicable to the larger plants having the more intelligent type of engineer and sufficient capital for proper equipment.

It was Mr. Harrington's belief, however, that the educational method must be supplemented more or less by the autocratic method. Recognizing the painful fact that every coal consumer in the country has not yet reached the point where he is willing to forego some of his own peculiar advantages for the sake of the public, there seems to be a necessity for some Governmental agency endowed with power to step into a man's plant and, after an intelligent examination of the situation, set forth imperatively the needs of such a plant. Care would have to be exercised and it would probably be necessary to have some organization or clearing house composed of a body of fair-minded, intelligent and experienced combustion engineers to which appeal could be taken in case any owner was dissatisfied with the requirements laid down by the inspector. There are so many cases wherein the conditions call loudly for simple remedies that it is more than likely that great good could thus be accomplished. Mr. Harrington closed by stating that he advocated a country-wide application of compulsory measures through state committees and all acting through a central clearing house such as the United States Bureau of Mines or some specially created body. As in the case of the enforcement of smoke ordinances, it is more than probable that compulsion would be required only in the exceptional cases. The mere fact that there was such a body competent to prescribe measures and insist upon enforcement would go a long way in inducing plant owners to spend their money for conservation measures. The only attractive feature of the whole program is that money thus spent reacts immediately to the advantage of the owner.

Coal Output Hampered by War Conditions

Professor Stoek reviewed the coal situation in war times. He showed how coal is related to everything connected with war and how badly it is needed to carry the war to a successful conclusion. The United States uses more coal per capita than any other nation, and as we have more of it, many might wonder why enough could not be obtained to meet all needs. In 1913 the coal production of the world was 1,478,000,000 tons. Of this the United States produced 570 million tons and Great Britain 322. In 1914 the production in Great Britain fell to 262 million tons, to 252 in 1915 and to 256 in 1916. Consequently the coal output in that country suffered as a result of the war. It would be reasonable to expect that there might be a similar falling off in this country.

The speaker briefly reviewed the coal resources of the Allies. All of the Belgian mines and most of the French mines are in the hands of the enemy. Italy needs 1,000,000 tons of American coal per month. Russia is a negligible quantity as far as the coal situation is concerned, and of the neutrals Holland and Switzerland are particularly scarce of coal.

Now that the immediate shortage is over, there is no occasion to feel too optimistic. The conditions producing last season's shortage are still with us, and there is little hope to increase the output. Conditions next winter may be even worse, unless large economies are effected.

In 1916 the output of coal in this country was 600,000,000 tons. To maintain the normal increase of 10 per cent. a year would call for an increased production of 60,000,000 tons. This would mean the opening of fifty new mines of the largest size or greatly increased capacity in existing mines. It would also mean a 10 per cent. increase in the 700,000 men employed last year, or 70,000 new men. With a decreasing labor supply the chance of increasing the output of present mines is small. New mines would require enormous capital investments and with slow deliveries new equipment could hardly be obtained in time to do much good. It would look as though all will have to make the best of it and get results by economizing as much as possible.

Professor Stoek reviewed the causes leading up to the coal shortage. The enormous demand, the high prices in effect last June, the attempted reorganization in Washington on the Peabody plan, the rumor of cheaper coal delaying its purchase and the final fixing of the price by the present Fuel Administration were all mentioned. When the busy transportation season in the fall arrived, there was a great shortage of coal and the unusually cold weather handicapped transportation. In addition there was a shortage of coal cars. To keep pace with the usual 10 per cent. increase in coal requires new cars in the same proportion. The increase in cars last year was only 4 per cent., and although the average time for the return trip of a coal car, 30 days, was reduced, there was not a sufficient number to meet the demand. A number of experiments such as pooling, revolutionized present methods and temporarily resulted in disorganization. In addition far too much waste material was shipped with the coal. The 50,000,000 increase in tonnage was counteracted by three times the quantity of dirt, slate and ash. Lack of coal was not due to export. We sent almost a negligible quantity to France.

The severe fuel restrictions imposed in Europe were reviewed and in conclusion the ways of saving coal proposed by our Fuel Administration, such as lightless nights, curtailing the schedule of electric roads, changing the running time, lessening the temperature in the cars, the skip-stop plan and coöperation of all employees. Many of these regulations were put into effect and resulted in saving. It is hard to make the consumer realize the enormous increase in demand and that his little saving with numerous other comparatively small savings made in reality a large aggregate. Efforts are being made to get in the hands of those using fuel, literature dealing with conservation and care in operation, not only in the power plant and the railway locomotive, but in the home as well.

With the railway facilities taken up, storage will not greatly augment the annual supply, but to relieve the situation it is evident that as much coal as possible should be obtained before the fall rush. Storing can be safely done if care is used to separate the fine from the coarse coal and to keep the pile away from external heat. Fine coal must have very little air or an abundance of air to carry away the heat of oxidation. When heat does show it is necessary to move the pile to cool it. With the difficulty of moving eliminated, high piles are just as safe as low ones, the burning generally starting near the surface and frequently at the top of the pile. Storage of screenings is risky unless under water. When storing in basements, the coal should never be drenched with water.

The discussion turned to storage, the possibility of large savings by the railways, which use one-quarter of the entire coal supply, and in the power-plant supervision over improvements that would effect economy. It is important to get a better grade of firemen and make the pay commensurate with the saving.

In conclusion it was strongly emphasized that as the coal production cannot be greatly increased, all must save—the railways, the industrial plant and heating in all buildings and the home. It is everybody's problem—the man at the mine, transportation and the consumer. All should be impressed with the need of saving and with the fact that if each "does his bit" it will tend to relieve the situation next winter.

Increase in Electric Rates

Public utilities commissions throughout the country are wrestling with the question of increased rates asked for by electric-light companies, which maintain that they are losing money under the present rates. It is not clear, however, as to whether the losses are based upon the falling off of revenue below actual operating expenses or are based upon lesser profits as compared with those before the beginning of the war. These increases in rates are considered by many of the users as being excessive and are being fought.

In the City of Mobile, Ala., the Mobile Electric Co. is desirous of increasing its present rates, which, according to the contract of Dec. 31, 1906, should remain in force perpetually. On Dec. 26, 1917, the city and the electric company entered into another contract for municipal lighting, which contains the provision that the electric company shall furnish customers with current on a meter basis at its regular schedule of rates. The rates under the perpetual contract are as follows: From 0 to 50 kw.-hr. per month inclusive, 10c. per kw.-hr.; from 51 to 150 kw.-hr. inclusive, 9c. per kw.-hr; from 151 to 300 kw.-hr. per month inclusive, 8c.; from 301 to 500 kw.-hr. inclusive, 7c. per kw.-hr.; from 501 to 1000 kw.-hr. inclusive, 6½c.

A discount of 2c. per kw.-hr. to be allowed if bills are paid within ten days after rendered, except that during the ten years of this contract the rate mentioned from 0 to 50 shall be 10c. per kw.-hr. less a discount of 3c. per kw.-hr. if paid within ten days after the rendering of the bill. All over 1000 kw.-hr. special contract. The minimum charge per customer is to be $1.25 per month less 25c. if paid within ten days after the bill has been rendered.

The proposed increased rates, to take effect Mar. 1, 1918, are as follows: First 50 kw.-hr. per month at 10c. per kw.-hr.; next 50 kw.-hr. at 9c.; next 100 kw.-hr. at 8c.; next 300 kw.-hr. at 7c.; next 1500 kw.-hr. at 6c.; excess kw.-hr. per month at 5c. per kw.-hr.

Prompt payment discount 10 per cent.

Minimum bill, $1 net per meter per month.

Legal steps have been taken to prevent the enforcement of the proposed increase in rates.

Another instance is that of the Wilmington & Philadelphia Traction Co., which has asked the public utility commission for permission to raise its rates. At the hearing it was brought out that the big users of electricity are willing to pay the proposed increase, but there are those who are opposed to an increase to the consumer for the lighting of homes.

The increase of rates was protested on the ground that the actual cost of production of current, even under present conditions, does not warrant it; that the actual cost now is at least 50 per cent. below the price that the company is receiving for the current; that the plant and equipment are sufficient to supply local needs, and that the abnormal demand for current is due almost exclusively to contracts with outside parties. Other objections were also brought to the foreground.

The proposed new schedule for electric current rates is as follows:

Lighting Rate: First 75 kw.-hr. used per month, 9½c. per kw.-hr.; next 150 kw.-hr., 8c.; next 175 kw.-hr., 7c.; all over 400 kw.-hr. used per month, 6c.

Minimum monthly service charge, for residence, 50c. per meter; for business, $1 per meter; 5 per cent. discount for cash on bills exceeding the minimum amounts when paid within 10 days from date of bill.

Retail Power: First 100 kw.-hr. used per month, 8½c. per kw.-hr.; next 100 kw.hr., 8c.; next 100 kw.-hr., 7c.; next 300 kw.-hr., 6c.; next 400 kw.-hr., 5c.; next 3000 kw.-hr., 4c.; next 26,000 kw.-hr., 3c.; all over 30,000 kw.-hr. used per month, 2½c. per kw.-hr.

Minimum monthly service charge, $1 per hp. for the first 10 hp., 75c. per hp. for the next 10 hp., 50c. per hp. for all over 20 hp.

No minimum less than $3 for direct-current or single-phase alternating; nor $5 for three-phase alternating; 5 per cent. discount for cash on bills exceeding the minimum amounts when paid within 10 days from date of bill.

High-Voltage Wholesale Power: First 50,000 kw.-hr. used per month, $0.02 per kw.-hr.; next 50,000, $0.019 per kw.-hr.; next 50,000 kw.-hr., $0.018 per kw.-hr.; all over 150,000 kw.-hr. used per month, $0.017 per kw.-hr.

In addition to the charges as per foregoing schedule add 25-100 of one mill for each 10c. of increase of cost of coal delivered at power plant in excess of $3.05 per long ton. Guarantee 50,000 kw.-hr. per month. Prices are net. Current metered at primary voltage.

That the central stations have been hard hit by the coal shortage this winter is well known. Some of the heating companies have been hit by the ruling of the public service commissions. For instance, the Kansas City Light and Power Co. has had its rates reduced from those which existed last August. The company claims that it lost $57,000 during the last three months of 1917 under the August rates and estimates that its loss under the new rate just fixed by the commission would have been at least $75,000.

The new rate is as follows: First 20,000 lb. of condensation, 85c. per 1000 lb.; next 180,000 lb., 70c.; next 500,000 lb., 60c.; all over 700,000 lb., 50c.; minimum on buildings, $5 a month from Oct. 1 to June 1; minimum for water heating and other purposes, $5 per month for 12 months.

Although it is said that the company is considering dismantling its $1,500,000 heating plant and quitting the heating business, it is doubtful that such a step will be carried out.

With the increase in rates sought by the central stations and the curtailment of power from time to time, the position of the isolated plants has been strengthened in that they have in most instances been able to operate, while neighboring plants depending upon central station service have suffered from more or less interrupted service.

Abandoning Isolated Plants in Favor of Central-Station Power

A public hearing was held on the afternoon of Mar. 4, before the Public Service Commission of New York, to obtain information as to whether coal could not be saved by the closing up of many small private plants and the substitution of electrical power generated in large central stations. Representatives of the United States Fuel Administration attended the hearing, as the question is one in which Dr. Garfield is vitally interested.

J. W. Lieb, vice-president and general manager of the New York Edison Co., repeated the statement he had made at an earlier hearing, that the shutting down of some 650 small steam-power plants in Manhattan and the Bronx and the taking over of their power business by the large central station would result in a saving of 500,000 tons of coal a year, as a conservative estimate. He based these figures on the savings obtained in the cases of sixty isolated plants that had been closed up in 1917 and that were now purchasing current from the New York Edison Co.

Mr. Lieb cited several instances, covering office and loft buildings, apartment houses and the like, in which the change from private-plant to central-station service had produced savings in coal consumption ranging from 19.8 per cent. to 60 per cent. When asked to name one or more of these instances specifically, however, Mr. Lieb emphatically refused, on the ground that the data in each case were private matters between the company and its patron, and that the figures could not with propriety be made public.

Inasmuch as the whole purpose—in fact, the sole purpose—of the investigation is to determine whether coal will actually be conserved by the substitution of central-station service for isolated-plant operation, it was a decided disappointment to find Mr. Lieb unwilling to divulge the name of a single one of the plants in which such marvelous savings had been effected. This secretive and sacrosanct attitude of the central-station representative was in marked contrast to the readiness with which the isolated-plant representatives were prepared to show their cost figures and to identify them by naming the plant location in every case.

W. J. Salmon, representing the Apex Leasing Co., stated that his company operated a private plant in which electric current was generated at a cost of 2c. per kw.-hr. The exhaust steam from the engine was used in connection with Turkish baths and heating in the building, and so the engine acted practically as a reducing valve. As a result, their current was obtained at a smaller cost than the Edison Co. would quote.

J. I. Straus testified that at the time R. H. Macy & Co. erected their building the New York Edison Co. was asked to estimate the probable current demand, with the idea of using central-station current. The Edison company's engineers estimated 1,250,000 kw.-hr. per year and quoted a rate of 3c. per kw.-hr. But they refused to accept a contract calling for the payment of $37,500 a year for current used. The reason, so Mr. Straus inferred, was that the estimate was ridiculously low. For, during the first year of operation of the private plant installed by his company, the current consumption was 2,000,000 kw.-hr., and in late years the figure has increased to 4,000,000 kw.-hr.

The testimony offered by Mr. Townsend, of the Hotel Majestic, was illuminating. During a ten-month period just before current was taken from the Edison company, the coal consumption was 5622 tons, costing $21,860. In a similar ten-month period after entering into a contract for central-station current, 5352 tons of coal was used for heating and cooking, at a cost of $26,342, and in addition $14,118 was paid to the Edison company for current. Thus, although there was an apparent decrease of 270 tons in coal consumption, the amount burned at the central station should be taken into account. The total cost was $18,600 greater than before—certainly a very expensive experiment in the use of central-station service.

It is not difficult to see why the owners of small plants are anxious to see this question openly discussed. If it could be proved that the abandonment of small plants in favor of central-station service would save coal, the Fuel Administrator might order the closing of such plants as a fuel-conservation expedient.

In a matter that may involve the sacrifice of costly equipment and the means of livelihood of many employees, there should be no secrecy or evasion. A fair decision as to the correct course to pursue should be based on well-authenticated facts and data, and not on mere estimates based on figures to which access is obtainable by only one party to the controversy, and an interested party at that.

The hearing will be resumed on Monday, Mar. 11.

New England's Shipping Needs

In an international shipping shortage such as the allied countries are now facing, it is difficult to determine what branch of war endeavor should have precedence over others. But with New England mills and factories turning out war supplies for the Allies, valued at billions of dollars, the Massachusetts Fuel Administration feels that it has a right to priority of bottoms at the Southern coal-loading points.

Notwithstanding at the present time 216,200 tons of shipping are engaged in bringing fuel to New England for commercial consumption, there is still a shortage of 115,000 tons of shipping. In other words, says the Boston *News Bureau*, Mr. Storrow has figured that with the threefold increase in industrial activity due to the war, a total of 351,000 tons of shipping must be available for the New England coal-carrying trade or production of essentials must be curtailed.

While the boats turned over to this district the last two days (Feb. 25 and 26) total 21,000 tons, they are still far short of the required amount and are providing only temporary relief to those factories that were verging on shutdown.

Through the western gateways Monday (Feb. 25) a total of 973 cars of both anthracite and bituminous coal were moved into New England. This is the second-best rail movement in a day and approaches the required maximum of rail-coal income of 1000 tons a day. This is for commercial purposes and does not include coal which must be moved by the railroads for their own consumption.

Locally, conditions are greatly improved and dealers' supplies on hand Tuesday morning, Feb. 26, showed an increase of nearly 6000 tons compared with Monday. Officials at the Fuel Administration are sending out warnings that while domestic conditions are more comfortable, all unnecessary use of coal for lighting or heating must still be prevented to keep New England war plants working.

Aviation Section, Signal Corps, Needs Skilled Workers

Ten thousand machinists, mechanics, chauffeurs and other skilled workers are needed at once by the Aviation Section, Signal Corps. The dependence of the air service on the most highly skilled men is being brought out more emphatically with every week of development. Practically 98 men out of every 100 in the service must be skilled in some branch of work.

Men registered in the draft may be inducted into this service by applying to their Local Draft Board. Men not registered may enlist at any Recruiting Office. Further information may be had by applying to the Aid Division, Personal Department, Washington, D. C. In either case they will be sent to San Antonia, Texas, for segregation by trades, followed by a brief course of instruction at the flying fields or at various factories and organized into squadrons mostly for service overseas.

New Publications

STEAM POWER PLANT ENGINEERING—By George F. Gebhardt. Fifth edition, rewritten and reset. Published by John Wiley & Sons, New York. Size, 6 x 9 in.; 1057 pages; 642 illustrations. Price, $4.

Few books are more highly valued among power-plant men than this one, the first edition of which appeared nearly ten years ago. Its wide use is its best commendation, especially when one reflects upon the remarkably rapid development in this field during the last decade. As the author says in the preface to this latest edition: "Revisions in 1909, 1911 and 1913 failed to keep pace with the art, and the task of recording correct practice appeared to be a hopeless one." He puts out the new edition, rewritten in great part, believing that radical changes are not likely to come in the immediate future. He has aimed, therefore, to produce a general work of stability, one which, assumably, he believes will present current practice for some time to come without the frequent editions which events of the past have made necessary. That Mr. Gebhardt is sound in this belief is the opinion of the reviewer. Certainly, no new types of prime movers of such revolutionary character as the steam turbine and "express" stokers and boilers are in sight on the horizon; and as the author has excellently covered these and allied subjects, he likely has put his work in more stable form than it has ever been. A period of refinements in detail and thorough quest of economical performance is now here, and these, as always before, the engineer must get from current journals and add the worth-while data to his loose-leaf notebook which forms a working supplement to a book like the one under review.

The most conspicuous additions to the work are the new chapters on Elementary Thermodynamics, Properties of Steam and the Properties of Dry and Saturated Air. In Chapter XXIV, Supplementary Elementary Thermodynamics of Steam Engine, the author has done a real service to the great number of men who use his book. There is not an integral sign in the chapter, which will gladden the hearts of 98 per cent. of his readers, and that he gets through the Carnot and Rankine cycles without the forbidding "log" will be appreciated by those studious operating men who have mastered by self-study, the use of letters and symbols in formulas, but have balked at logarithms. The table of properties of saturated steam, which are from Marks and Davis, are well arranged, the pressures selected being such that they cover all but the most unusual found in practice.

No less welcome in this book is Chapter XXV, Supplementary on the Properties of Air—Dry, Saturated and Partially Saturated. Gebhardt has needed this chapter on account of the air problems that in ever-growing numbers confront the engineer in these days of widening application of refrigeration and humidifying processes. Goodenough's air tables, the most widely used, are included in this chapter.

Gebhardt has greatly enlarged upon his treatment of fuels and combustion. Suffice it to say that in this latest edition he has presented the most suitable treatment of these subjects, judged by the needs of power-plant men, that the reviewer has ever found, even in books devoted exclusively to fuels and the theory and chemistry of combustion—the theory and chemistry, mind; not those details of technique of combustion as it must be carried on in boiler furnaces. For these he refers the reader to articles in engineering periodicals, and the references are many.

That part of Chapter II devoted to fuel oil would please more if it had, among the many excellent tables it contains, one giving the equivalent heating values of some of the coals and fuel oils widely used along the Atlantic coast. The value of such a table may be questioned, it is true; but it is useful, and its use will grow, particularly in New England, where fuel oil is said to now displace one million tons of coal yearly.

The reviewer regretted to find that in the sectional views of settings of horizontal return-tubular boilers the shells are shown only 28 in. above the grate. Of course, this is satisfactory for anthracite; but the author would have done well to show these shells at least nearly twice as far above the grate. He owes it to the book to help discourage the installation of these low settings. He does give a whole page to drawings of the Chicago No. 8 setting, which has a wing wall and in which the shell is 36 in. above the grate.

The chapter on stokers is almost wholly descriptive, and the power dump plate is not shown, though brief mention is made of it There is little or nothing said about clinker grinders as applied to some underfeed stokers, and the reviewer finds no mention of development in cooling the furnace side walls or of the desirability of doing this to avoid clinker accumulating here and seriously affecting the operation of the stoker. Stoker operation is too vital a part of power-plant practice to receive such scant treatment in a book which deals so well with the operation of other power-plant apparatus. But then, no other book, so far as the reviewer knows, covers this subject even half well; so perhaps Mr. Gebhardt should not be too severely criticized for this omission.

There is something familiar about the chart showing the effect of temperature on strength of materials on page 238, and the reviewer thinks Mr. Gebhardt forgot to credit "Power," Feb. 13, 1917, p. 208, for it. But then, he has referred so often to "Power" that this oversight is not serious. The chart was plotted by the reviewer from data obtained from the "Valve World," and Mr. Gebhardt's chart is a reproduction.

The reviewer is sure that the author's many readers will wish he devoted a paragraph or two to the relative advantages of cast iron and steel for economizers, and sketched tendencies in America and Europe in these materials as used in economizers. It is an important part of power-plant practice now that high pressures are "coming in" and safety and long periods of uninterrupted service from boilers are demanded.

That Maurice Leblanc has but recently brought out his multijector (steam jet) air pump probably accounts for the lack of reference to it in the chapter devoted to air pumps. The "Radojet," a purely American steam-jet air pump of recent development, is described.

On page 531 appears the statement: "No better material than admiralty brass has been found, and it is the standard for modern condenser practice." The reviewer believes that it should be made clear that while this is true for salt water, Muntz metal is now the standard for condenser tubes passing fresh water.

Except for the fore part, the chapter on steam turbines is wholly descriptive, with too much omitted about turbine oiling systems which, by the way, are not as broadly treated of in the chapter on lubrication as one wishes. So far as the reviewer knows, nothing has transpired to impair the hopes engineers have in the Ljungström turbine, yet no mention of it is found in the chapter dealing with turbines.

This fifth edition is indeed a creditable work and the reviewer regrets that space forbids more about it here. Reviewing it is like eating peanuts—one does not want to stop. The subjects embraced are so numerous and well presented that only in rare instances does one care to criticize; but rather, to suggest at these places, realizing the enormity of the fatiguing task of compiling such numerous and varied data. Chapter XVIII, pp. 845-890, on Finance and Economics—Cost of Power, is, in the reviewer's mind the best extant. Mr. Gebhardt is to be congratulated.

Obituary

Adam Cook, the senior member of the firm of Adam Cook's Sons, manufacturers of Albany grease, died on Feb. 19, at his residence, 148 West 78th St., New York City, after an illness extending over a period of seventeen weeks. Adam Cook was born in Albany, N. Y., in 1367, and was a graduate of the Albany Military Academy. At an early age he became a member of the firm of Adam Cook's Sons, which his father founded at Albany, in 1868.

Personal

Harrison Williams has succeeded Samuel Scovil as president of the Cleveland (Ohio) Electric Illuminating Co.

H. P. Curtiss has been appointed representative for the New England States of the Clarage Fan Co., of Kalamazoo, Mich., with office at 120 Milk St., Boston, Mass.

J. S. Green, formerly erecting engineer and master mechanic for the Wickwire Steel Co., of Buffalo, N. Y., has resigned to accept a position as master mechanic for the Edgewater Steel Co., Pittsburgh, Penn.

Engineering Affairs

The New England Water Works Association will hold a meeting on Mar. 13, at the Hotel Brunswick, Copley Square, Boston, Mass.

The American Society of Mechanical Engineers announces the following Section meetings: Baltimore, Md., Mar. 13; Chicago, Mar. 15; Philadelphia, Mar. 26; Bridgeport, Conn., Mar. 27.

The New York Chapter of the American Association of Engineers will hold its next regular meeting on Mar. 13, at the McAlpin Hotel. E. W. McKnight, of the First Canadian Expeditionary Forces, will speak on "War-Time Experiences."

The American Institute of Electrical Engineers announces the following Section meetings: Baltimore, Md., Mar. 18; subject, "Air Brakes;" Chicago, Mar. 25; subject, "Electrochemical Processes," by Charles F. Burges; Portland, Apr. 2.

The Minnesota Electrical Association will hold its annual convention at the Hotel Radisson, Minneapolis, Mar. 11-13. Among the important papers to be presented are "Minnesota Water Powers," by R. J. Thomas, superintendent of the St. Anthony Falls Water Power Co., and "Iron-Wire Transmission," by Prof. W. T. Ryan, of the University of Minnesota.

The American Institute of Electrical Engineers will hold an inter-section meeting in Pittsburgh, Apr. 9 and in New York, Apr. 12. Two papers will be presented: "The Physical Conception of the Operation of the Single-Phase Induction Motor," by B. G. Lamme; and "The Theory of the Phase Converter and the Single-Phase Induction Motor," by R. E. Hellmund.

Miscellaneous News

Boiler Explosion Kills Three in Providence—The explosion of a boiler in the Mount Pleasant Laundry, Providence, R. I., Monday, Mar. 4, is reported to have killed three persons, injured four and completely wrecked the laundry building. A "Power" representative is now after the details of the explosion.

A Heating Boiler Exploded at the Crown garage, Main St., Peoria, Ill., on Feb. 20, wrecking the back wall of the garage, shattering the boiler walls into thousands of pieces and doing damage estimated at nearly $10,000. The boiler has only been installed a year, and the cause of the explosion is unknown.

A Boiler Exploded at the sawmill of James Roberts, seven miles northeast of Clanton, Ala., on Feb. 26, instantly killing three workmen and injuring several others. There were two big boilers standing side by side at the mill, and from some unknown cause one of them exploded with such terrific force that it caused the other boiler also to blow to bits, breaking its iron part.

Business Items

Flynn & Emrich Co., of Baltimore, Md., are manufacturing the Huber hand stoker, which was formerly made by the Huber Grate Bar and Stoking Co., a description of which was published on page 665 of the Nov. 4, 1913, issue of "Power." It will be remembered that the movement of the grate advances the coal to the rear of the furnace, sifts out the ashes, and at the same time breaks up the fire. The movement of the grate is accomplished by levers operated from the front of the boiler.

The Schütte & Koerting Co. will continue business in all its lines and to its full capacity, as always, under a board of directors reconstructed as follows by the Alien Property Custodian of the United States: E. Pusey Passmore, governor of the Federal Reserve Bank, Philadelphia; Ralph J. Baker, assistant general counsel of the Alien Property Custodian; D. W. Hildreth, treasurer of Schütte & Koerting Co.; T. H. Johnston, of Schütte & Koerting Co.; Charles S. Caldwell, president, Corn Exchange National Bank, Philadelphia. The new board has elected the following officers: President, Charles S. Caldwell; treasurer, D. W. Hildreth; secretary, Ralph J. Baker.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]

PROPOSED CONSTRUCTION

Cal., Oakdale—An agreement has been reached between the Sierra & San Francisco Power Co. and the Oakdale and South San Joaquin Irrigation Districts by which the power company will build reservoir on the south fork of the Stanislaus River. This work will be followed by that of doubling the output of the hydro-electric plants. Estimated cost, between $2,000,000 and $3,000,000.

Calif., Redding—City plans to sell $40,000 bonds to build an electric-lighting plant soon. W. D. Tillotson, City Attorney.

Calif., Sacramento—The Pacific Gas and Electric Co. plans to extend its transmission line from here to Guinda, Humsey and Brooks. C. W. McKillip, Mgr.

D. C., Wash.—A. L. Flint, Purchasing Agent, Panama Canal, is in the market for generator sets, copper cable, transformers, etc.

Ga., Sandersville—City plans to rebuild its electric-light and water plants which were recently destroyed by fire. I. N. Lozier, Supt.

Ill., Evanston—The Public Service Co. of Northern Illinois, Chicago, plans to build an extension to its transmission line from Evanston to Highland Park. G. H. Lukes, Gen. Supt.

Ill., Grafton—The Grafton Electric and Power Co., recently incorporated, plans to build an electric-lighting plant here. W. Chapman, Jerseyville, Attorney.

Kan., Dighton—City plans election soon to vote on a bond issue for enlarging its electric-lighting and water-works system. D. E. Bradstreet, Mayor.

Ky., Greenville—The W. G. Duncan Coal Co. is having plans prepared by C. M. Means, Engr., Oliver Bldg., Pittsburgh, Penn., for the erection of a new 1-story, 60 x 80-ft. brick and steel power plant.

Neb., Clarkson—City plans to extend and improve its electric-lighting plant. L. J. Roubineck, Supt.

Neb., Juniata—City voted $7000 bonds at a recent election for the erection of a transmission line from here to Hastings; also the installation of an electric lighting system. Noted Feb. 8.

N. Y., Chenango Forks—The Binghamton Bridge Co., Press Bldg., Binghamton, will not receive bids in April for the erection of a brick and steel power house, steel penstocks, etc. When plans have matured, the work will be done by their own forces. Noted Feb. 26.

N. Y., Clyde—The Clyde Glass Works plans to remodel its plant and completely re-equip same by installing power plant with 500 hp. capacity.

N. Y., Buffalo—(East Buffalo)—The Delaware, Lackawanna and Western R.R. is in the market for power plant equipment. G. J. Ray, Hoboken, Ch. Engr.

Ohio, Salem—The Salem Lighting Co. has been authorized by the War Department to build a power line from here to the Morgan plant at Alliance.

Okla., Ada—The Oklahoma Power and Transmission Co. plans to build a transmission line to supply the surrounding towns with current.

N. H., Claremont—The Claremont Power Co. plans to equip a new substation. J. G. Menut, Mgr.

Penn., Coudersport—The Home Electric Co. plans to issue $22,000 bonds; the proceeds will be used to extend and improve its plant and system. D. B. Belknap, Mgr.

Penn., Indian Creek—The Mountain Water Supply Co. is having plans prepared by King & Wightman, Engrs., 1513 Walnut St., Philadelphia, for a new 30 x 70-ft. power plant to be erected soon.

Penn., Philadelphia—The Coca Butter Manufacturing Co. is having plans prepared by A. F. Sauer & Co., Engr., 908 Chestnut St., for a new 1-story, 30 x 60-ft brick power house to be erected at 2626 Martha St.

Penn., Pittsburgh—The West Penn Power Co. has been authorized by the Public Service Commission, to issue $1,500,000 bonds; the proceeds will be used to extend and improve its plant and system.

S. D., Newark—L. Severson has gained control of the electric-lighting plant here and plans to increase the capacity of the plant by installing new machinery.

Penn., Williamsport—The Lycoming Rubber Co. is having plans prepared by Lockwood Greene & Co., Engrs., 60 Federal St., Boston, for the erection of a 1-story brick and steel power house. H. S. Marlor, Supt. Noted Jan. 29.

S. D., Scotland—City plans an election to vote on the issuance of $35,000 bonds for the erection of an electric-lighting plant.

Wis., Brodhead—The Brodhead Electric Light and Power Co. plans to rebuild and remodel its electric-lighting plant. K. Guelson, Supt.

N. S., Halifax—The Department of Public Works plans to build an electric-lighting plant. L. F. Monashan, Clerk.

The Unexpected

Contributed by C. H. WILLEY.

IT IS the unexpected that always happens, and how often we could avoid disaster or humiliation if we kept our eyes open. A young engineer of my acquaintance recently came to see me and pour out his troubles in the hope that I could aid him.

HE WAS in charge of a factory power plant and had gotten along pretty well for several years, keeping things running. He felt quite content with his job and really sort of prided himself that things went so smoothly. And now he had received a bump that startled him, and he professed he was up against it and worried. The factory owners had called him into the office and told him that they wished him to go over the power plant with a fine-tooth comb and submit a report on items that were causing waste of steam or that, in his opinion, were so antiquated and inefficient that they could be dispensed with. They also wished him to make recommendations as to new and modern devices that would return a reasonable interest on the investment.

THEY explained that as fuel prices were now so high and the prospects were that they would remain so for an indefinite length of time, they desired to bring the old plant up to a more modern standard. This rather large order caught the young engineer wholly unprepared. When asking me to assist him, he said: "Gee! I never expected the old crabs would ever spend any money on improvements. Why, every time I sent in a requisition for supplies, they grumbled over it and cut it down, and now here they are asking me to remodel the plant!"

SEEING that he was up against it, I tried to help him out and succeeded. I wonder how many more of his kind are working blindly along each day. These are days of quick decisions on the part of power-plant and factory owners. Many who have been skimping along on old dilapidated equipment all at once decide to yank out the old junk and adopt the modern.

THE new is always trying to crowd out the old everywhere, and to those engineers who would keep up with the times I would give this advice: Keep your eyes peeled for new ideas and be alert to grasp them. Get acquainted with every up-to-date device that could be applied to your plant to aid efficiency and economy. Do not allow the small details of everyday work to crowd out new thoughts and modern ideas. Become a spare-time student of your trade paper—it will keep you abreast of the times.

Wreck of a Thirty-five Thousand Kilowatt Turbine

An account of the wreck of a 35,000-kw. horizontal single-cylinder impulse steam turbine in the O Street Station of the Boston Elevated Railway Co., Boston, Mass., Feb. 14, 1918

A 35,000-kw. 20-stage 1500-r.p.m. 25-cycle horizontal single-cylinder impulse steam turbine in the O Street Station of the Boston Elevated Railway Co. was completely disabled and seriously damaged while in service Thursday, Feb. 14, 1918. There were no casualties and no one was injured. A distorted cast-iron diaphragm in the 18th stage presumably fouled the 18th wheel, breaking off the buckets, after which the buckets and diaphragms from the 18th stage on to the last, or 20th, wheel, also the entire casing, were destroyed. There are excellent photographs of the wreck in existence but are not available for publication without the consent of the manufacturers of the turbine, which consent is refused. A turbine of a type similar to that which was wrecked is, however, shown in Figs. 1 and 2.

To get a proper perspective of this accident one should go back a year ago, when the turbine was installed. At this time trouble of a nature similar to that which wrecked the turbine was experienced; the date was Feb. 14, 1917. At that time the 18th diaphragm became distorted; that is, it deflected at its edge in the direction of the 18th wheel, rubbed the buckets where they join the wheel and stripped the buckets from the 18th and 19th wheels, seriously damaging the 18th and 19th diaphragms. This happened when the machine was being given trial runs. Rubbing began and the throttle was tripped, after which the damage to the buckets and diaphragms followed. When the buckets let go, the speed was below the normal 1500; perhaps 1000 or 1200 r.p.m.—no one knows.

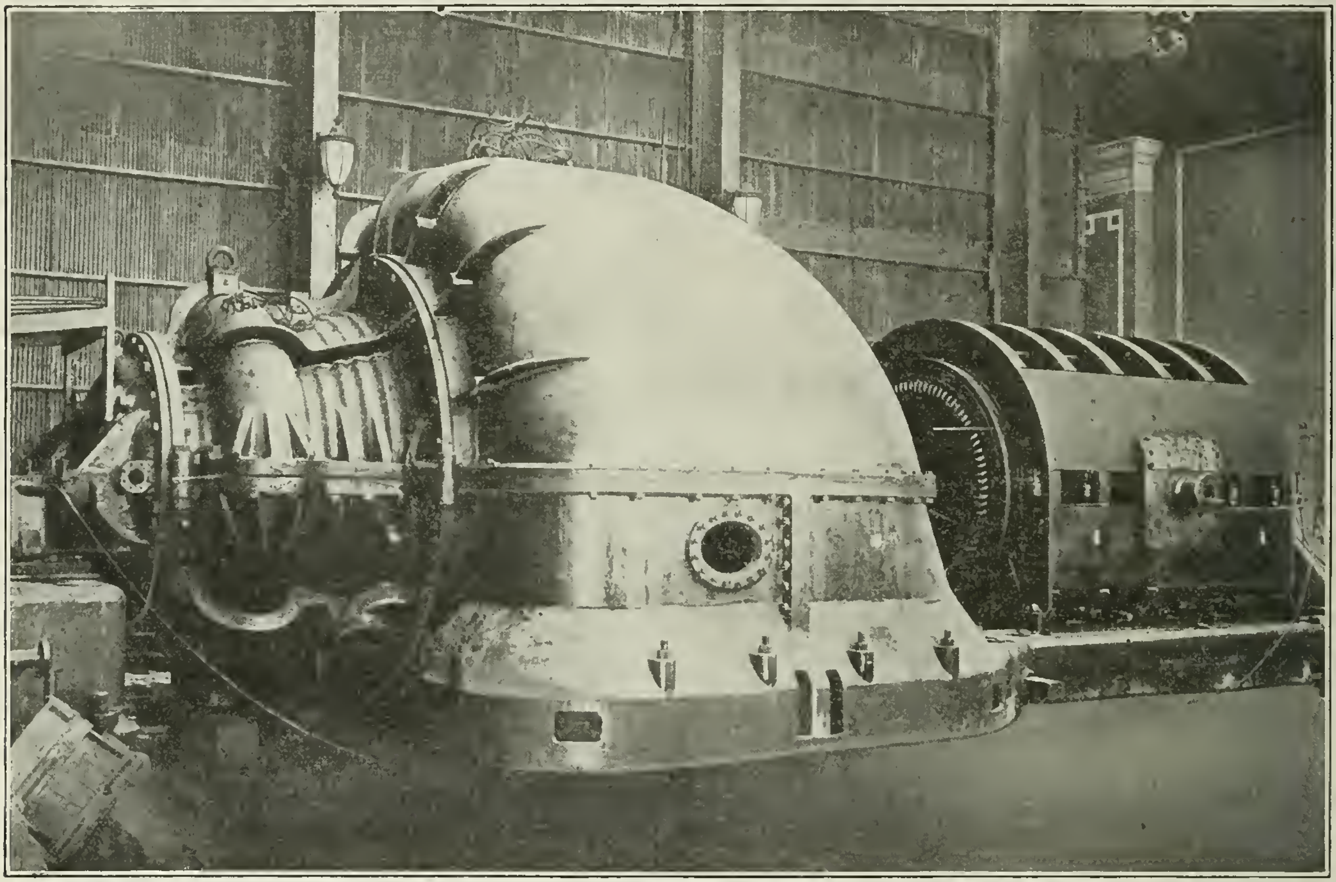

FIG. 1. CASING OF TURBINE OF TYPE SIMILAR TO THAT DAMAGED IN BOSTON

After the accident of Feb. 14, 1917, the capacity was reduced to 20,000 kw. from Mar. 17 to May 23, while repair parts were being made, by locking closed the secondary valve, which admits steam to the 7th stage. The repair parts in place and the machine in service, annoyance was given because the machine would not carry the load with its swings of 2500 kw. above the rated 35,000 kw. under the operating conditions. When these swings came, the cycles dropped from the normal 25 to 24. The purchaser was most anxious that the turbine carry the swings, and it was suggested that nineteen 1⅛-in. holes to be drilled in the eighth diaphragm in front of the eighth wheel. See Figs. 3 and 4. The holes were drilled to allow high pressure steam to that stage. The turbine then carried these swings.

The machine was designed for 200 lb. gage pressure at the turbine throttle, 200 deg. F. superheat and 29 in. vacuum at 30 in. barometer. There was a pressure drop of 4 lb. in the steam line between the boilers and the throttle, or from 200 lb. to 196 lb.; the drop through the governor valves was also slightly more than normal. The builder states that on Aug. 15 last, with 188.7 lb. gage pressure at the throttle, 132 deg. F. superheat and 28.7 in. vacuum, the turbine carried 36,500 kw., and that based on these figures the capacity would be 39,000 kw. under contract conditions.

Rumor has had it that thrust-bearing trouble was responsible for the accident of Feb. 14, 1918. In view of this it is well to point out that the most authoritative statement claims that what little thrust-bearing trouble did arise did not present itself until December, 1917. The trouble was not inherent in the bearing, but was due to oil of poor quality, it having been used for too long a time, as seems evident from the gradual rise in temperature of the oil and from the chocolate-colored deposit left on the bearing. After this incident new oil was put in and the bearing burned out a week later, caused likely by interference with the oil circulation. Slight changes were made to the circulating system, and the machine was put in service on Jan. 26, 1918, after which no further trouble was experienced with the bearing. So, evidently the bearing had no influence whatever on the present accident.

With the foregoing in mind, take up the details of the accident. On Feb. 14, 1918, at 4:55 p.m., when the evening peak load was mounting, the machine was heard to rub and observed to vibrate. Members of the operating crew climbed on top of the platform to adjust the thrust bearing, hoping to stop the rubbing and consequent vibration. The statements of these men say that the first vibration was heavy, that it was of the nature of a shock, after which there came a second with such evident commotion within the casing as to cause all hands to seek safety by running to cover.

At 5:01 p.m., six minutes after the first sign of serious rubbing, the damage was completed and pieces of metal had ceased to fly about the room. [This time is variously given as 3, 4, 5 and 6 minutes; but 6 minutes is the most authoritative as it is that given by the men who were handling the machine and the switchboard.] The period during which pieces of the turbine were flying about and while the low-pressure end of the rotor and the casing were going to pieces was likely not more than 30 seconds.

Now to go back to the time that the first severe rubbing was heard. At this time the Central Station of the same company, which, of course is tied in with the O Street Station, dropped its load of about 10,000 kw. owing to a station blowout. Prior to this the machine now damaged was carrying 32,000 kw. This turbine was practically the only unit to take the system's load—there having been some trouble at the Lincoln Wharf Station—and tried to take all the load dropped when the blowout occurred, by opening wide its secondary valve. The quick opening of this valve so suddenly increased the steam pressure in the low-pressure stages that the impact was probably sufficient either to initially and seriously distort the 18th dia-

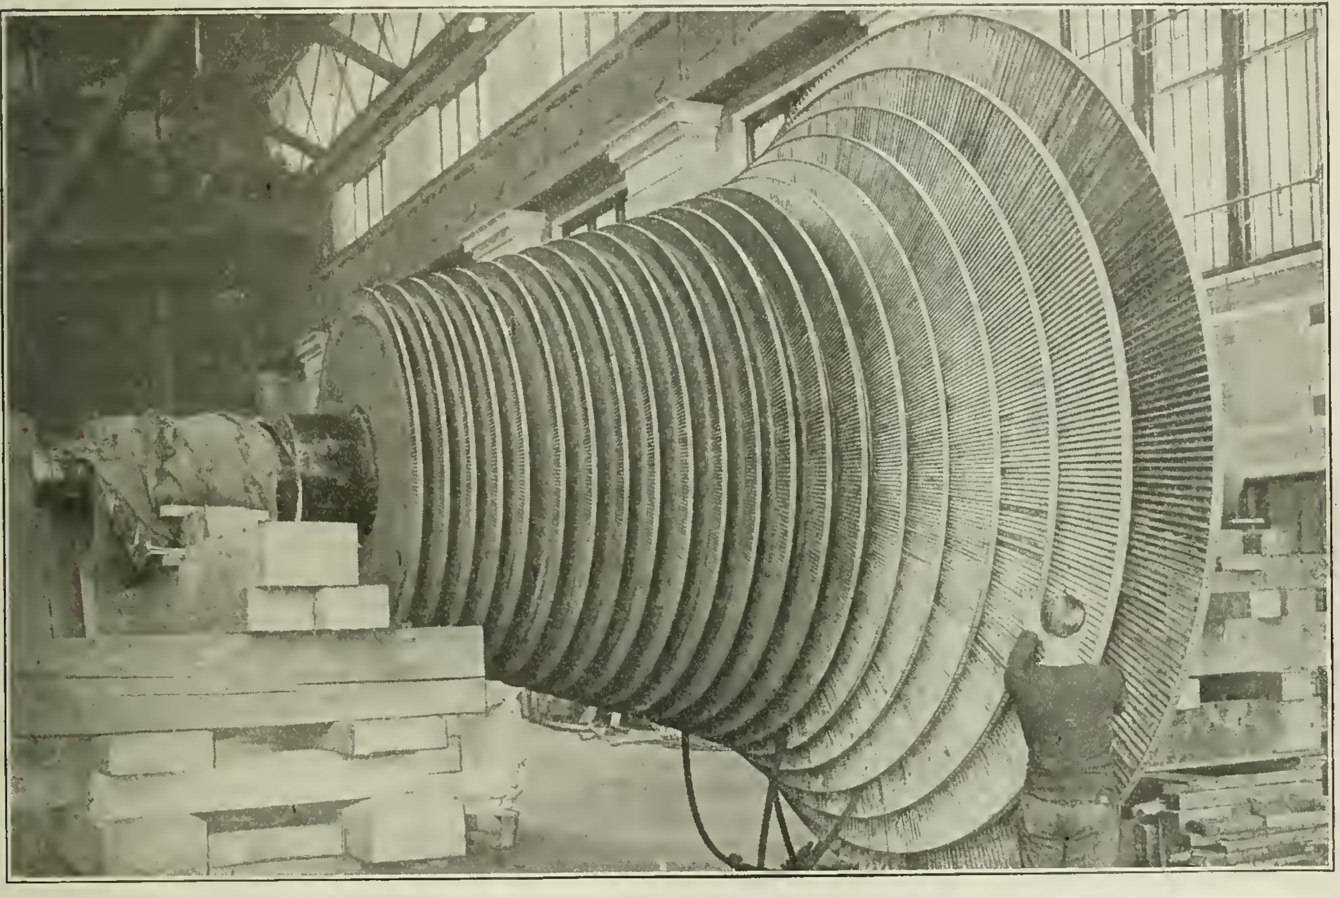

FIG. 2. ROTOR OF THE TURBINE THE CASING OF WHICH IS SHOWN IN FIG. 1

phragm or to further distort it if already deflected, sufficiently to make it further foul the 18th wheel.

When the secondary valve opened, the machine was said to take on 37,000 kw. Whether it took but 37,000 or, because of the momentum of the rotor, took every kilowatt of that 10,000, no one knows for it seems there was no instrument to record the load it did take. But it appears certain that the machine took a very heavy load and took it with the suddenness of a hammer blow. The cycles had dropped from the normal 25 to 24 when the switchboard operator noticed that the turbine was carrying 37,000 kw. Unable to stop the rubbing, the operator on the floor signaled the switchboard man to take off some load, which he did, dropping it to 32,000 kw. It was soon after this that the turbine went to pieces. The buckets on the 18th wheel ripped off, they fouled the 19th diaphragm, which in turn fouled the 19th wheel and the 20th diaphragm.

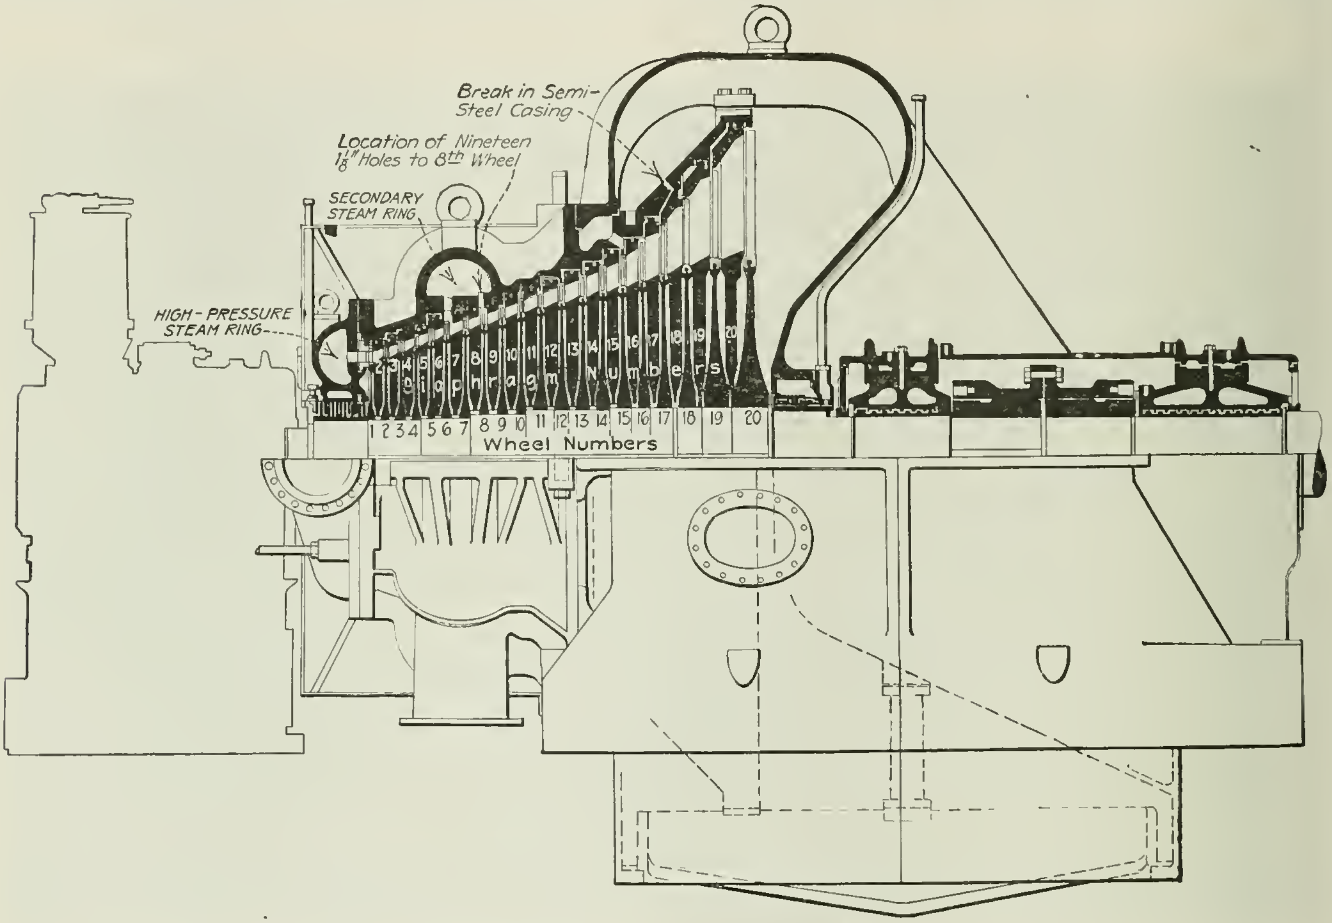

FIG. 3. LONGITUDINAL SECTION OF 35,000-KW. TURBINE DAMAGED IN BOSTON ACCIDENT

It is interesting to note that the buckets from the 18th wheel are broken identically as were the buckets from this wheel in the accident of a year ago. In the recent accident the same evidence of heating of the buckets where they join the wheel is apparent as was apparent on the buckets damaged a year ago. Fig. 5 shows where the buckets were rubbed and how they left the wheel. These buckets are indeed tough, as shown in Fig. 7. The 20th, or last, wheel has all or nearly all its buckets, though they are severely bent and twisted.

Reference to Figs. 3 and 6 shows that a break occurred in the semi-steel frame which holds the diaphragms in the low-pressure end. This conical frame dropped into the condenser, crushing the tubes for a depth of about two feet. When this frame broke, it is probable that the 19th and 20th diaphragms let down on the shaft, or more correctly on the wheelbases, and either revolved with the shaft, then broke due to centrifugal force, or they were broken at the time their supporting frame cracked by reason of being struck by fragments from other stages. These diaphragms, like all others in the low-pressure end of this and other large turbines, were of cast iron. The centrifugal force may have broken them, but at any rate they were broken in many pieces, and these were hurled against the outside casing with force enough to blow out the whole end of this casing and break the great web or bracket, that supports the bearings on the generator side of the turbine. The significant fact is that these diaphragms are the only large pieces of metal to completely break up and leave the turbine. It was some of these pieces that went through the roof and terra cotta temporary end wall of the building. The direction taken by the principal fragments that left the turbine was radially of the shaft, though five pieces went through the building wall near the generator end of the shaft. A piece weighing 70 lb. went through one of the switchboard gallery windows, coming to rest at the other side of the gallery room. One large chunk of diaphragm fell about a quarter of a mile from the scene of the accident. A man was punching the time clock in the turbine room, the clock being at an angle of about 45 deg. from the turbine, when the crash came. As he punched the clock, a piece of metal tore through the board holding the time cards.

There are some interesting speculations as to what broke the conical semi-steel casing which held the low-pressure diaphragms and which inclosed the last five wheels. The man qualified to speak most authoritatively, that is, the eminent designer of the turbine, shows by calculations that high-pressure steam at that point, caused by possible closure of the buckets in the 19th diaphragm, could not do it, as the pressure on the ledges *A*, *B* and *C*, Fig. 6, probably was not more than 186 lb. at most. He thinks that the expansion of the 18th diaphragm, caused by the diaphragm rubbing the buckets on the 18th wheel, may have forced the ring *D*, which is the outside or ring of the 18th diaphragm, to exert pressure enough on the casing to fracture the latter. Others think that it was broken by pieces of diaphragm being jammed against it. A combination of these causes seems not improbable.

The whole turbine casing is ruined, being severely cracked at the low-pressure end, with other smaller cracks extending to the high-pressure end. As stated, the great bracket, or web, supporting the bearings between the turbine and generator dropped away, letting the bearings free. The low-pressure labyrinth packing was destroyed. There was thrust enough to break the collars at the bearings and to push the exciter, mounted on the end of the mainshaft, forward sufficiently to break the four spider brackets supporting the extreme end of the exciter shaft. The collars on the thrust bearing at the high-pressure end are intact.

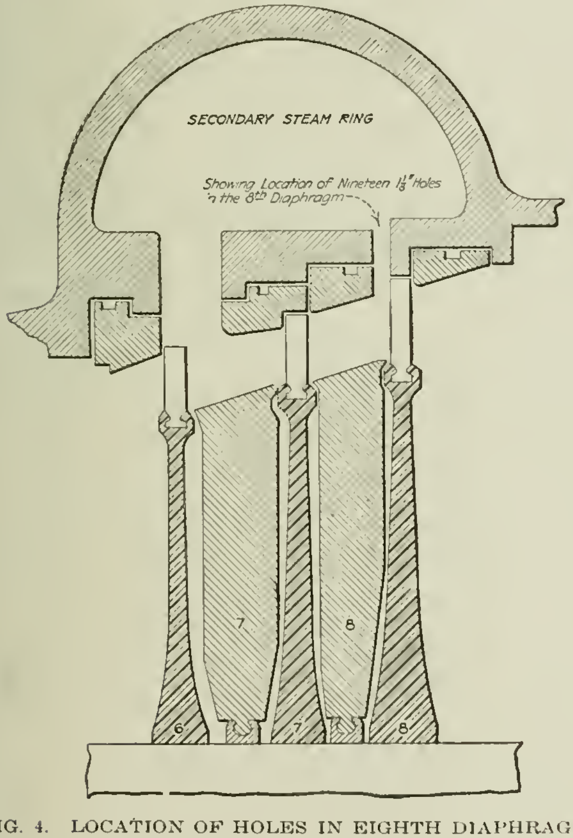

FIG. 4. LOCATION OF HOLES IN EIGHTH DIAPHRAGM

All wheels and diaphragms up to and including the 17th stage are intact. The 18th, 19th and 20th wheels are intact, though their blading is either gone or ruined. There is one small piece out of the rim of the 20th wheel, broken out, presumably, by being struck a tremendous blow by a fragment of diaphragm.

Fortunately, the automatic throttle valve which controls steam to the turbine tripped, either from vibration or because one of the operating crew tripped it by hand. The men do not remember tripping the valve, and one of those present who most likely would trip it is not sure whether he did or did not. It was most fortunate that this did trip, for if it had not one can but conjecture where the damage and loss of life may have ended. Vibration probably tripped the valve, as valves of this design are held open by a catch resting on a knife-edge steel.

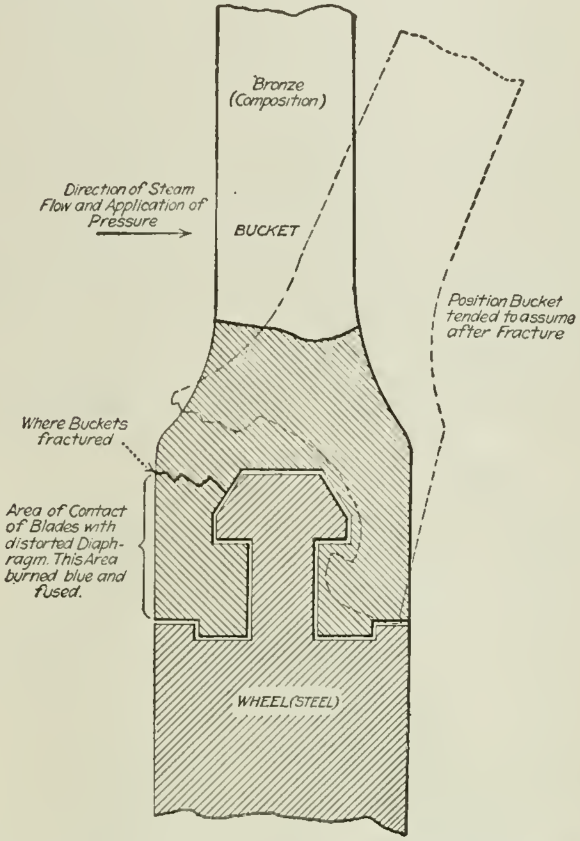

FIG. 5. HOW BUCKETS ON THE EIGHTH WHEEL WERE BROKEN

That the turbine wheels, especially the 20th, are intact is most gratifying. Nothing could more thoroughly prove the correctness of the designer's calculations and more completely convince one of the adequacy of the factor of safety of these wheels.

There were some who were apprehensive about this 20th wheel. In fact, the Massachusetts Institute of Technology was engaged to check up the stresses in the wheel, determine the factor of safety, etc. The results of these checking tests showed astonishingly close agreement with the designer's values. The factor of safety was a little more than four.

On going over the matter with characteristic thoroughness, the professors at "Tech" were in no way apprehensive about the wheel going to pieces. They did express an opinion that because of the shape of the wheel (thick at the hub, then growing thin as the rim is approached) fracture might develop if the wheel were subjected to sudden extreme temperature changes, which of course are not likely in usual operation. Superheat "shoots" through a turbine under certain load conditions; but the wheels, diaphragms or shaft probably absorb an insignificant amount of it. Breaking of the vacuum will cause a more or less sudden change in temperature of the turbine rotor; but the writer does not at this time know of a case where damage or even minor trouble has come from this cause.

The 20th wheel, and presumably the others, has a tensile strength of 130,000 lb. and an elastic limit of 73,000 lb. per sq.in. It is 12 ft. 1 in. diameter, and its tip speed at 1500 r.p.m. is 950 ft. per second.

An engineer of unusual experience with turbines, who desires to remain anonymous, expressed his opinion that before these wheels would fracture or burst they would stretch so much as to become loose on the shaft and cease rotating at dangerous speed. Perhaps this would happen. But one wonders if the wheel would not rub the shaft, fuse both shaft and wheel, and freeze fast. It is recent experience, however, that in some cases of overspeed of turbine rotors, the wheels have been found loose on the shaft when examined after overspeeding occurred.

One wonders if these wheels in large-capacity turbines would ever, except under failure of both governors to function should all load be suddenly lost, reach a speed sufficient to fracture them. In the experiments by the engineering staff of the Public Service Electric Co. of New Jersey, conducted May, 1916, the last or final wheel of an 1800-r.p.m. 25,000-kw. turbine was about four hours being brought to a speed of nearly 3600 r.p.m., or to 198 per cent. of normal, and notwithstanding that a motor of 450 hp. was used to turn the wheel and that steam was impinged upon the blades to assist in revolving it. This gives one an idea of the windage of these wheels. The wheel in question did not fracture, and though painted and marked at the shaft and hub, showed no indications of having slipped or stretched.

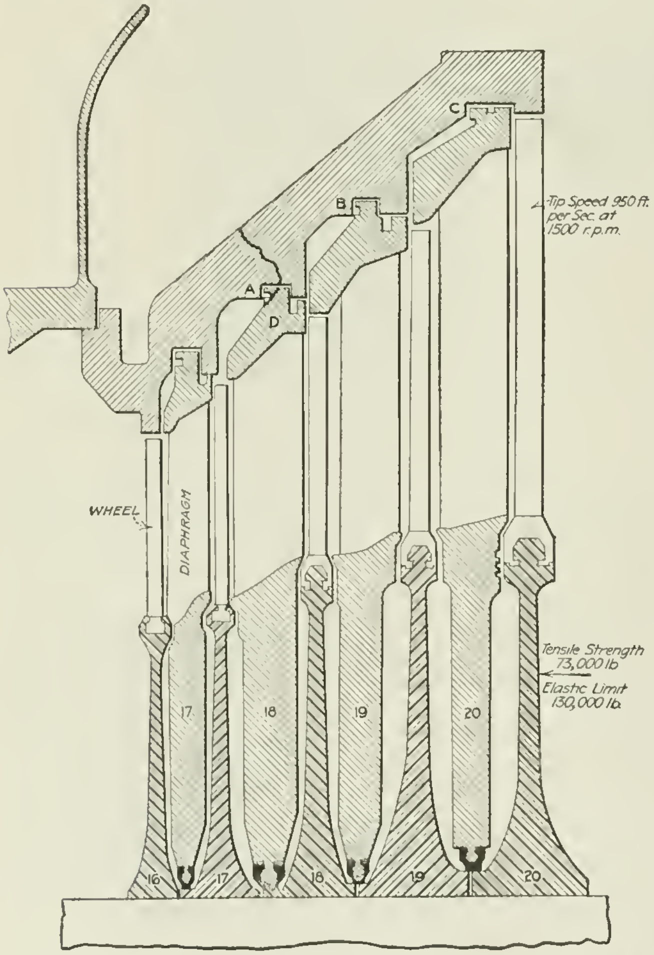

FIG. 6. SECTION OF LAST WHEELS AND DIAPHRAGMS TOGETHER WITH DIAPHRAGM SUPPORT FRAME, WHICH BROKE AS SHOWN

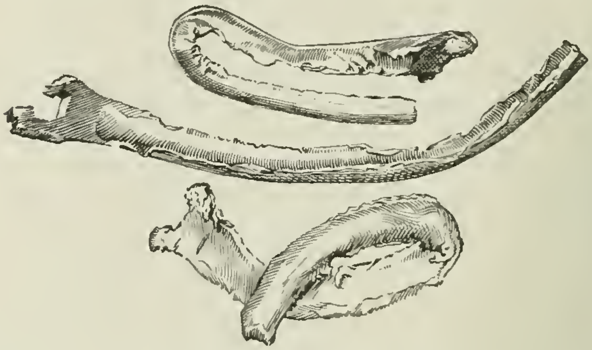

FIG. 7. TYPICAL BLADES FROM THE BOSTON TURBINE SKETCHED AFTER THE WRECK

The Boston wheel was certainly subjected to jamming and impact from broken blading and pieces released from diaphragms, and it withstood these severe shocks while subjected to the centrifugal force due to rotation at the normal speed. This demonstration of resistance is most assuring.

The machine was carrying 29 in. vacuum at the time the low-pressure end of the casing was blown out. Just what effect the sudden release of the vacuum had, one can study out at his leisure.

It is probable that steel will be used in the last stages of the Boston turbine when it is repaired. The builders are, of course, taking steps to avoid a repetition of this accident, and with their wide experience plus that gained in this accident, this should not be difficult, especially as no fundamental changes in design seem necessary.

It is likely that difficulties of manufacture of steel diaphragms as well, perhaps, as cost reasons account for the universal use of cast iron. In making diaphragms one large ring and one large disk, connected by nozzles or stationary buckets, have to be cast. The claim of some persons is that the steel nozzles would likely burn off or become seriously weakened if the disks and rings were cast of steel. However, by pouring and venting in a number of places burning of the nozzles where they join the ring and disk can probably be avoided.

When the Boston machine gets its new casing, the great web supporting the bearings at the generator end will be of steel for reasons of greater safety than cast iron insures.

The turbine with its condenser represented an investment of about $335,000.

The details of the accident described, some general observations are in order: Naturally, the question uppermost in the minds of designers and engineers is whether cast iron should or should not be used for large turbine diaphragm construction. This much is obvious: Cast iron should not be used where it is likely to be subjected to the stresses imposed by the centrifugal force that a steam-turbine diaphragm would be called upon to resist if it revolved with the shaft. But this is the first case the writer knows of where a diaphragm has revolved with the shaft. Certain it is that if there are no probabilities of these large diaphragms being let down on the shaft, and if it is found that cast iron for these relatively thin disks is not subject to too great deflection, cast iron seems suitable, as the diaphragms now in use have a high factor of safety against rupture by normal stage pressure.

Since these high-capacity turbines, with their rotations which give wheel-tip speeds of nearly 1000 ft. per sec., have appeared, all have learned that rubbing of a diaphragm on its adjacent wheel and vice versa must be immediately stopped to avoid the loss of blading or more serious trouble. The element of time is most vital. Take the Boston case: If the throttle had been tripped at the first sign of serious rubbing or vibration, it is probable that the turbine would have needed nothing more than new buckets for the 18th wheel. To go further with the "if," for the good it may do "the next time she rubs hard," the casing would, in the Boston case, simply have had to be lifted off, the loose blades cleared away and the machine closed up and put back on the line—a delay, of course, but not a delay plus a direct loss of, say, $200,000.

THE HUMAN SIDE MUST NOT BE NEGLECTED

The point is that turbine operators not only must be alert, sober and intelligent men, but must be made to realize that they should never take a narrow chance when the safe course is obvious and practicable. The watch engineer on the floor must know the peculiarities of his machines and have judgment quick and decisive enough to know when he should attempt adjustments to thrust bearing or governor, or whether he should signal for load reduction or trip the throttle. This is the human side of the development of turbine art. It must not be neglected, it must develop with the machine, for the machine is right and the human has the quality of adaptation.

Anyone not a switchboard operator would, when he looks at the scarred walls, the broken wire-glass in the switchboard gallery windows and the other turbines down the room at the O Street Station, turn over in his mind or revise his opinion as to placing turbines with their shafts transversely of the room. If the Boston machine had been placed transversely, the other turbines down the room might have been considerably damaged. There are excellent arguments for both transverse and longitudinal positions. The Boston case is an impressive one for the latter.

Just a word about turbine accidents in general. Some folks are foolish enough to try to give the impression that machines may be made, that they are made, so as to be "absolutely free from accident." No sensible engineer ever made such a statement. Be assured of that. Only the other day, in discussing this question with one of the most eminent turbine designers, a man to whom the world owes a deep debt of gratitude for his contribution to the art, he said: "The man who thinks this can be done is indeed foolish."

Accidents are as much a part of the progress in machine design as illness and death are parts of animal life. They are the impetus stimulants that reveal the danger zones and help us the sooner to get out of them.

Heat Carried to the Chimney by the Flue Gases

In a recent issue of the *Stevens Indicator* E. A. Uehling, M. E., derives the following formulas for determining the amount of heat carried off in the chimney gases.

CO = Percentage of CO in the flue gas;
CO_2 = Percentage of CO_2 in the flue gas;
H = Weight of available hydrogen per pound of carbon in fuel;
M = Weight of moisture in fuel per pound of carbon;
t = Temperature of air supplied for combustion;
T = Temperature of flue gases on leaving boiler;
V = Weight of water vapor in the air used to burn one pound of carbon;
W = Weight of water of hydration (water combined in fuel) per pound of carbon.

H is the weight of free hydrogen available for combustion per pound of carbon as distinct from the hydrogen already combined with oxygen and forming the moisture and the water of hydration in the fuel. W is the weight of water $\left(O + \frac{O}{8}\right)$ that is formed by the combination of the oxygen, O, in the fuel per pound of carbon with hydrogen, in which form it is combined in the fuel as water of hydration as distinct from the moisture which is present but uncombined.

Heat Carried Away by the Dry Gases

$$\left(0.24 + \frac{58.46}{CO_2}\right) \times (T - t)$$

Heat Carried Away Through Incomplete Combustion

$$\frac{10{,}150 \times CO}{CO + CO_2} + \text{other combustibles difficult to determine and generally negligible}$$

Heat Carried Away by Water Vapor in the Air

$$V \times \left(\frac{117}{CO_2} + 3.8H\right) \times (T - t)$$

Heat Carried Away by the H_2O from the Combustion of Hydrogen

$$4.32 \times H \times (T - t)$$

Heat Carried Away by the Moisture and Water of Hydration in the Fuel

$$(M + W) \times (0.48 \times T + 1080 - t)$$

Theoretical Maximum CO_2 Obtainable from Fuel Containing Hydrogen

$$\frac{21}{1 + 2.38H}$$

Percentage of Excess Air Supplied

$$\frac{2100}{CO_2(1 + 3H)} - \frac{100 + 238H}{1 + 3H}$$

Percentage of Oxygen in Gas

$$21 - (1 + 2.38H)\ CO_2$$

Be careful that no pieces of rubber gaskets work through the steam pipe into the steam chest of a throttling engine. Wrecks have occurred due to the governor valve being blocked open by pieces of packing.

Training Power-Plant Men for the Navy

By WILLARD CONNELY, U. S. N. R. F.

How ship fitters and gas engineers get expert free training for duty with Uncle Sam's fleets.

NOT all the naval pipefitters, steam and gas engineers, water tenders and boiler men can be trained at sea. There is neither room nor time for that. Schools of instruction on our coasts and inland, too, are adding more and more men to their classes every day. Quite as frequently the raw recruits of four months back pass their examinations at these training stations and are dispatched with all speed to their receiving ships, whose power rooms the new bluejackets enter familiarly, chafing for action.

A school's remoteness from the ocean does not deter the Navy Department from authorizing thereat trade instruction for bluejackets. For instance, witness the training base established at Dunwoody Industrial Institute, Minneapolis, now producing for the fleets nearly three thousand artisan specialists a year.

Dunwoody Institute is a free trade school, and although the Navy now makes demands on the major portion of its facilities, it continues to hold civilian classes in day, evening and extension courses. Of the ten departments now making dextrous naval craftsmen out of bluejacket apprentices, among the foremost are those teaching the foundry and boiler men, the pipefitters, and the gas, steam and oil engineers. Three general divisions of power-plant processes are here involved: Navy blacksmiths in a power plant would do the repairing, metal workers would make new parts, navy gas engineers would represent operation. The naval detachment, under the command of Ensign Colby Dodge, U. S. N., has now a smoothly running routine worked out by the commandant and by Acting Director Kavel of the Institute.

Work in Forging and Welding

The blacksmithing and boiler men begin naturally at the forge. Preliminary exercises involve making various foundry tools, then a week or two building iron racks and the like, and the blacksmiths come to the most significant branch of their course—oxyacetylene welding. At the welding tables the bluejackets repair broken or cracked machine parts. They are dentists to stripped gears. They rebuild a cylinder, a cam or an engine connecting-rod. All this time the ironworkers are having daily classroom work too, in heat treatment of metals, metallography, and related mathematics. Open discussion is encouraged, that the older jackies who have been previously at the trade may relate their power-plant experiences.

The men are admitted to the Soo line car shops in St. Paul, where they tackle welding jobs so comparatively gigantic that nothing thereafter on a battleship will seem too formidable. From a motor-boat engine cylinder to the stripped boiler of a big freight locomotive is a significant leap. After two months in the car foundries the naval apprentices rightly believe themselves to have become fairly competent welders. While acquiring skill at the Soo shops, the blacksmiths alternate training periods in the boiler room at Dunwoody, where at stated hours they assume the responsibility of the boiler operation. This duty they share with men in other departments also, men whose general scheme of training covers a survey of power-house methods. Four to five months, in sum, round out a man in the foregoing vocation, whereupon he goes aboard ship.

Power-plant men will see at once that the instruction of these metal-worker bluejackets is essentially in productive work.

The course in pipe fitting, which embraces training in coppersmithing, tinsmithing, sheet- and galvanized-iron construction, covers mathematics through solid geometry, catalog study, freehand sketching and laying out of water, vapor and low-pressure heating systems, plan reading and estimating quantities.

Gas-Engine Instruction

Outfitted at the start with a set of hand tools and all the standard coppersmith stakes, the bluejackets in the power-plant course are then acquainted with the crimping machine, the bar folder for stovepipe, the cornice brake to bend up edges, the squaring and circle shears, and rolls for forming. Working in tin, the students make mess pans, dust pans, drinking cups, cooking measures and funnels; then they proceed to such marine articles as tees, elbows, bunker lamps and ventilators. While such power-house accessories as oil cans, oil feeders, air chambers and ventilators are made of copper, the more important exercises allied to pipe fitting comprise a cuff joint, a cramped-seam pipe, a long bend, short bend, return and offset bends, a formed tee, and single and double saddle branches.

Through the naval students' gas-engine class at Dunwoody lies the quickest avenue for a recruit to attain the rating of a chief petty officer. This exigency is created by the sudden demand of the Government for experienced gas-engine men to make up the engineer crews of the new submarine chasers. Now that enlistments in the Navy are closed to men of draft age (unless their numbers are obviously far down the list), perhaps the best chance remains for engineers between between 31 and 35 years old, because of their more substantial knowledge of the craft. However, competent men between 18 and 21 are gladly enrolled in this course. The point is, a man who enlists as seaman for training in the submarine-chaser corps can in four months arrive at the rating of chief machinist's mate, provided he knows what he knows. This chance cannot be duplicated, nor will it last for long.

To be sure, not all Dunwoody gas-engine apprentices are pointing for the submarine-chaser service. Some of the bluejackets cannot make all the requirements, which embody a proven ability to handle men and to stand the shaking of the high seas in a small boat. Gas-engine students not so qualified are trained for motor-boat pilots, operating the boats that ply between ships of a fleet or from a ship out in the harbor to shore. On a basis of five days' instruction per week, with Saturday mornings for review and tests, the gas-engine men spend three half-days in the Dunwoody auto shop, tearing down, repairing and reassembling gasoline engines, three quarter-days with classwork on theory of engines and starting and lighting, three quarter-days in the testing laboratory, operating oil and steam launch engines, taking horsepower tests, setting valves and taking indicator cards. The remaining four half-days have been employed at a near-by lake, running motor boats and learning to approach docks properly. Through the winter the boat work is indoors, overhauling and repairing parts. The auto shop is fitted with gas engines of various types from one to twelve cylinders, with axles and transmissions of equivalent diversity. The ignition room has an electric dynamometer for testing horsepower, with a profusion of carburetors, magnetos, starting and lighting systems.

ENGINEER STUDENTS IN TRAINING FOR SERVICE ABOARD SUBMARINE CHASERS

For a comprehensive idea of this highly developed course, a résumé of the work from week to week may be taken. First the men are given classroom lectures on engine types. They make a study of the basic principles of these types, including both two- and four-stroke-cycle kinds, and a survey of general construction and arrangement of parts. The crank case and attached parts are next taken up. This subject covers bearings, crankshafts, flywheels, counterbalancing and connecting-rods. The third week is devoted to cylinder parts, their assembly and correct fitting, concluding with observations on pistons and rings, the whole covering both two- and four-stroke-cycle cylinders. Valves, springs and timing follow, and their correlative subjects of camshafts and timing gears.

Cooling systems claim the fifth week, during which pumps and piping of all recognized sorts are analyzed and examined. The natural corrollary of this topic is lubrication. A description of each lubricating system is necessary, involving questions and answers on oils and their distinguishing characteristics. The seventh week is given to carburetion, under these heads: Fuels and their uses, mixing valves, carburetor types, fuel tanks, piping systems, manifolds, mufflers, inlet, exhaust, cutouts.

By this time the bluejackets are required to apply their knowledge directly to the operation of the Norfolk Navy Yard engine for a week, and then to the Van Blerck engine. On both these highly important pieces of naval machinery each sailor is examined, asked to describe all parts discussed and studied to date.

Three weeks are given to the subject of ignition, covering a description of systems, wiring, coils, interrupters and distributors, magnetos and generators. Two weeks more are taken up with starting and lighting, in the same department. Generators and motors, wiring and cutouts, storage batteries and lights are the subdivisions of this period. Then comes a week of transmission systems with instruction in gear sets, reverse gears, thrust bearings, propeller shaft and propeller.

Oil engines are considered separately. Five days' intensive application to this type is given, with horsepower tests and valve notations, so that by this time the bluejacket is familiar with every kind of engine in wide use—gas, steam or oil. Finishing training succeeds on the Norfolk and Van Blerck types, with a study of all features not previously inspected.

The final teaching period is occupied with boat construction. A bluejacket who knows how to run a motor boat should also know how to build and repair. In the gas-engine class he winds up with learning displacement theory, hull construction, engine mounting, control and signals.

As fast as the bluejackets can complete this course satisfactorily they are sent to receiving ships or transferred to Columbia University for a four weeks' supplementary training on actual submarine-chaser apparatus. The time required by the average student in gas-engine work at Dunwoody is four to five months. At the school of mechanical engineering at Columbia the sailors have a week in the electrical laboratory, a week in the mechanical laboratory and two weeks of outside training under the supervision of instructors. The first week of outside work is in the assembly department of a chaser yard somewhere on the Atlantic coast, and the final week before going to sea is spent studying the engine itself in the process of manufacture.

Before a gas engineer is recommended for transfer to Columbia he must pass a rigid personal examination, aside from his technical test, by Ensign Dodge. Two companies of Dunwoody men have qualified and are now at sea.

Anthracite Coal from Lignite

By Charles Philip Norton

A lawyer named Fiske, whose standing and connections command respect, startled the Seattle public in February by announcing that after years of experimentation he had perfected a system of coal distillation by which the full power value of lignites could be utilized, saving the byproducts of gas, coal tar and oils and producing a manufactured coal containing seven-eighths of the fuel value of the best Pennsylvania anthracite. In the process of making coke from bituminous coal the byproducts are saved to some extent, but anthracite coal goes to market untreated.

Mr. Fiske said he had no stock to sell, no scheme to promote. In proof of his patriotism he proffered his formulas to Franklin K. Lane, Secretary of the Interior, for the use of the Government. Together with his offer to Secretary Lane, Mr. Fiske urged that the Government appropriate $500,000 and establish the first coal-manufacturing plant, utilizing lignites, with a capacity of 100,000 tons per annum. The volume of byproducts, he said, would be enormous and profitable. He guaranteed that the coal manufactured by his process from the practically worthless lignites would be almost as good as the best anthracite and that it would stand every test in use.

Mr. Fiske is a man of independent means. He said that if he desired to make a fortune he would engage in such manufacture upon a colossal scale and in a few years would rank with Rockefeller, but that his sole desire at this time was to "swat the Kaiser." "It is almost a crime, in my opinion," said Mr. Fiske, "to waste the byproducts in coal—products which we need so badly in everyday life."

The Fiske manufactured coal is not even second cousin to the well-known briquet, according to his statement. The latter, he says, simply is coal in a different form, containing all the byproduct elements, while his coal is divested of these products *in toto*. He further says:

> If the Government is afraid to experiment with my process, but will appropriate the necessary capital for the initial plant, I would be perfectly willing to operate the plant upon a lease and commercial basis, paying the Government 7 per cent. on the investment, and would put up a bond in any amount to guarantee the Government against possibility of loss. Being a Westerner, believing in immediate action in a matter so vital as this, which promises permanent insurance against coal famine as well as a never-ending supply of the valuable byproducts of coal, I am urging the Government to do it now.

In almost every Western State and in Northwestern Canada there are vast deposits of lignite coal which is undesirable as fuel in its natural state. Mr. Fiske is of the opinion that the United States should lead in coal distillation. He says:

> It is no secret process, but is well known to scientists and power engineers the world over. The stupidity of governments is such, however, that none has yet started this industry. Once begun, it will develop rapidly into a colossal enterprise. Large capital is required to get immediate results. That's why I am anxious to have the Government take hold of it.

He said his process and formulas were the result of many years of scientific study and experimentation; that he was willing to make a gift of the whole thing to Uncle Sam, provided the Government would use it to help win the war.

Warrior Steam Plant of the Alabama Power Company

By W. B. West

A stand-by steam station to be held for taking care of emergency loads. There is but one 25,000-kw. turbo-generator unit, the largest in the South. Two additional units are to be installed. Coal is obtained from a mine but a few hundred feet distant.

PRIOR to August, 1917, the Alabama Power Co., operating in North Alabama, with headquarters at Birmingham, generated most of its power at Lock No. 12 on the Coosa River, thirty miles below Birmingham, and had but a 10,000-kw. steam plant in reserve. This plant is at East Gadsden, Ala.[1] At Lock No. 12 there are five 13,500-kw. vertical waterwheel generators. When the river gets low, these generators cannot carry the load, and it was seen that the East Gadsden plant would soon be too small to take care of an emergency. The company officials, therefore, decided to construct another steam plant on the banks of the Warrior River (Fig. 1) about forty miles northwest of Birmingham, to be held in reserve. By the time the first unit in this plant was started, the load in the Birmingham district, at Gadsden and at Anniston, had become so heavy as to make it necessary to put it into operation at once.

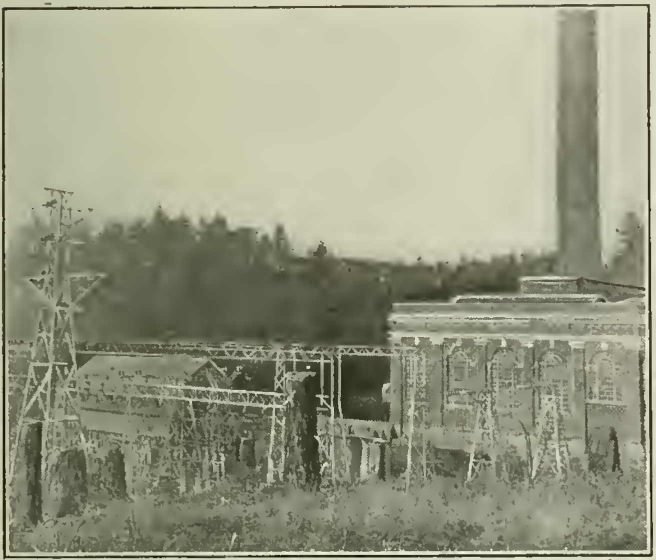

FIG. 1. GENERAL VIEW OF THE POWER HOUSE AND SUBSTATION

Since that time the Government has decided to use power generated at this plant for the operation of its industries at Muscle Shoals on the Tennessee River (Near Sheffield, Ala.) until the $12,000,000 dam at that place is completed. Construction crews are hastening the completion of the transmission line. The power plant to serve the Government projects will be enlarged and extended at an initial cost of $3,000,000. The size of the new units to be installed has not yet been determined. It is certain, however, that they will have a capacity of over 25,000 kv.-a. each.

It is interesting to note that the Warrior River plant is at an apex of a large imaginary triangle whose sides inclose the Birmingham district. Lock No. 12 is at another apex, and the East Gadsden plant is at the third. While most of the load is still carried by the Lock No. 12 plant, it is necessary to keep the Warrior River plant in operation except during periods of high water on the Coosa River.

The location of the new plant was determined largely by the available supply of coal and water. Ground was broken early in July, 1916, and in spite of the congested freight situation and manufacturing delays, the first unit was started in August, 1917. While not a record performance, yet in view of the fact that the main equipment was much delayed, it compares well with similar installations even in the less active periods.

In general plan the plant follows pretty well the established practice for an installation of its size. The foun-

dations are carried down to bedrock, which lies fairly level about fourteen feet below grade. The basement walls of the turbine room and the walls of the cold well are carried down to rock, which is below the river-water level; but in the boiler room the columns are carried on piers founded on rock.

The boiler room at present is 86 x 120 ft. in the clear and accommodates six water-tube boilers, Fig. 2, each of 1200 normal horsepower with 150 deg. superheat. Five of the stokers are the underfeed tuyere type. All are driven by two stoker engines.

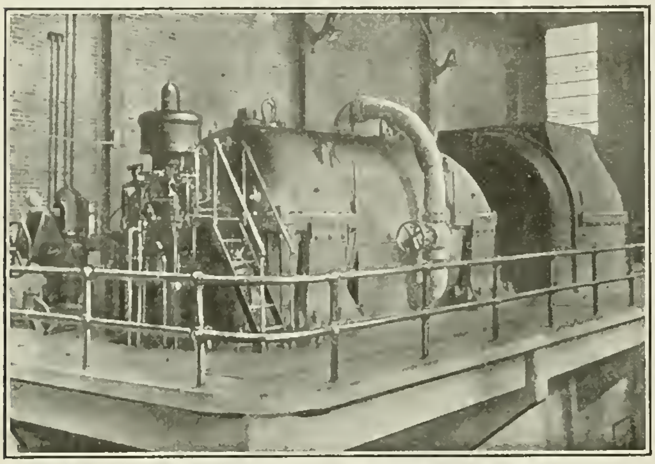

FIG. 4. THE 25,000 KV.-A. TURBO-GENERATOR

The fact that coal is mined only a few hundred yards up the river from the plant is one of its interesting features. The plan of establishing a power plant at the mouth of a coal mine has been advocated by many of the leading engineers, but as yet very few plants have been so located. After it leaves the mines the coal is carried to the crusher in cars drawn by electric locomotive. From the crusher it is delivered upon a 24-in. belt conveyor driven from the lower end. The belt conveyor discharges into a steel bunker having a capacity of 600 tons. From the bunker the coal passes into the automatic registering scales. Each stoker is equipped with two sets of scales. The total weighing capacity of the twelve scales is 9600 lb. per min. Ordinarily, the daily coal consumption is about 450 tons.

At present the turbine room is 40 x 86 ft. in the clear and is served by a 60-ton overhead crane. In order to make room for the two additional units that are to be installed at once for the Government, the turbine room will be enlarged to 258 x 40 ft. Another crane, larger than the one in use at present, will also be installed in the near future.

At present there is one 25,000-kw.-a., turbo-generator served by a jet condenser located in the basement (see Fig. 4). Circulating water is pumped from the river and goes back by force of gravity. The generator is cooled by means of a water-driven blower located in the basement.

Water for boiler feed is drawn either from the discharge or from the intake canal and is measured by venturi meters. Centrifugal feed pumps are used. The boiler piping follows the usual lines.

The generator is equipped with a direct-connected exciter, Fig. 3. There is also a motor-generator exciter set and a turbine-driven exciter. The latter supplies power to haul coal from the mines to the plant. It is a 100-kw. 230-volt machine, making 3600 r.p.m. The main generator speed is 1800 r.p.m. The current is three-phase 60-cycle generated at 6600 volts and is stepped up to 45,000 volts for distribution. The switching system consists of duplicate busses with remote-controlled solenoid-operated oil switches. The feeder circuits are equipped with three-phase aluminum-cell lightning arresters.

The installation was designed and constructed by the company's engineers and construction department, O. G. Thorlow, chief engineer, and J. A. Sernit, chief electrical engineer having charge of the work. A. R. Gilchrist is in charge of construction.

Speed-Reduction Gear

Small steam turbines and electric motors to be cheap and efficient must run at a higher speed than the machinery which they drive. Reciprocating engines, on the other hand, often run much slower than the generators, fans, pumps, etc., for which they furnish power. To step the speed of the prime mover up or down to meet the requirements of the driven apparatus is a problem which the engineer must often solve.

The ideal thing would be a self-contained device which could be inserted in the shaft connecting the prime mover with the load and which would receive the power at the motor speed on one side and deliver it at the desired speed on the other. Such a device is the Turbo-Gear, shown in Fig. 1, and manufactured by the Poole Engineering and Machine Co., of Woodberry, Baltimore, Md. If the speed is to be stepped down, the swiftly running motor or turbine is connected to the smaller shaft at the right, and the larger shaft, in the same axial line at the left, rotates in the same direction at the desired speed. If the speed is to be stepped up, the prime mover is connected to the larger shaft.

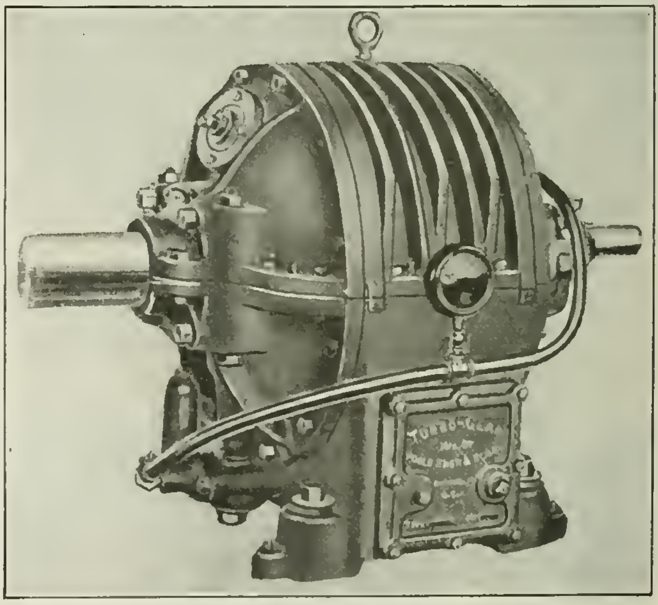

FIG. 1. EXTERIOR OF THE TURBO-GEAR

The method by which the change is effected is shown in Fig. 2. If the shafts or pins upon which the intermediate or planet gears *C* turn, were held in a fixed position, it is apparent that if the internal gear *A* were rotated counterclockwise it would rotate each of the intermediate gears *C* counterclockwise upon its own axis and these would drive the pinion *B* in a clockwise direction. But suppose the internal gear *A* to be held stationary and the planet gears *C* to be mounted in a carrier, Fig. 3, free to turn upon its axis. If now the pinion *B* is revolved in a clockwise direction, it will turn the gears *C* each upon its own axis in a counterclockwise direction, but they will roll around upon the internal gear *A*, carrying the cage which supports their axes, and the shaft to which it is attached, around in a clockwise direction, like the actuating pinion.

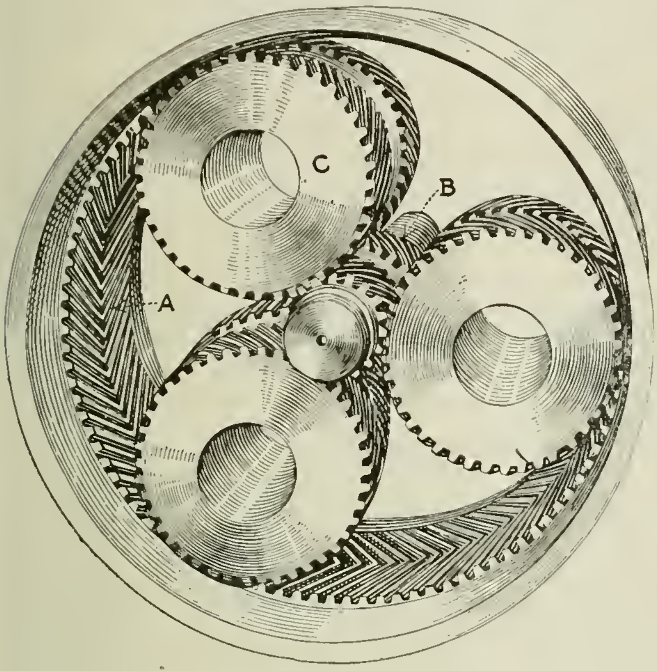

FIG. 2. DETAILS OF THE GEAR MEMBER

The assembled mechanism is shown in longitudinal and cross-section in Fig. 4. The pinion shaft is supported at the left in a ring-oiled bearing, and at the right its reduced end is carried in a bronze bushing in the axis of the low-speed shaft. The low-speed member is supported on both sides of the gears by ball bearings.

An eccentric on the low-speed shaft within the casing actuates the plunger of a pump by which oil is forced to all the bearings and gear faces through the channels shown. This oil gravitates back to a chamber in the base containing a cooling coil, from which chamber the cooled oil is taken by the pump through a filter.

The change in speed depends upon the ratio of the pinion to the large internal gear, the intermediates or planet gears being simply carriers. The gear must be designed with reference not only to the change in speed, but to the load to be transmitted and to the actual as well as the relative speeds. As an indication of the range of speeds and horsepower capacity offered, the following data are given relative to five types of Turbo-Gears:

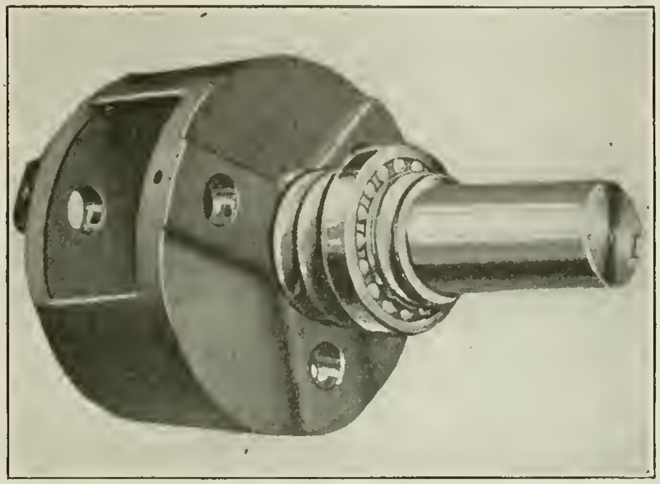

FIG. 3. THE CARRIER AND SLOW-SPEED BEARING

Type A, with 24 separate ratios from 4 : 1 to 7 : 1, good for from 1 to 50 hp.;
Type B, with 51 separate ratios from 4 : 1 to 10 : 1, good for from 1 to 130 hp.;
Type C, with 71 separate ratios from 4 : 1 to 13 : 1, good for from 1 to 240 hp.;
Type D, with 105 separate ratios from 4 : 1 to 19 : 1, good for from 1 to 400 hp.;
Type E, with 135 separate ratios from 4 : 1 to 17 : 1, good for from 1 to 800 hp.;

The Poole company is, however, able to furnish gears capable of transmitting any load up to 20,000 hp. with speed ratios varying from 4 : 1 up, which ought to meet any case likely to occur in ordinary practice.

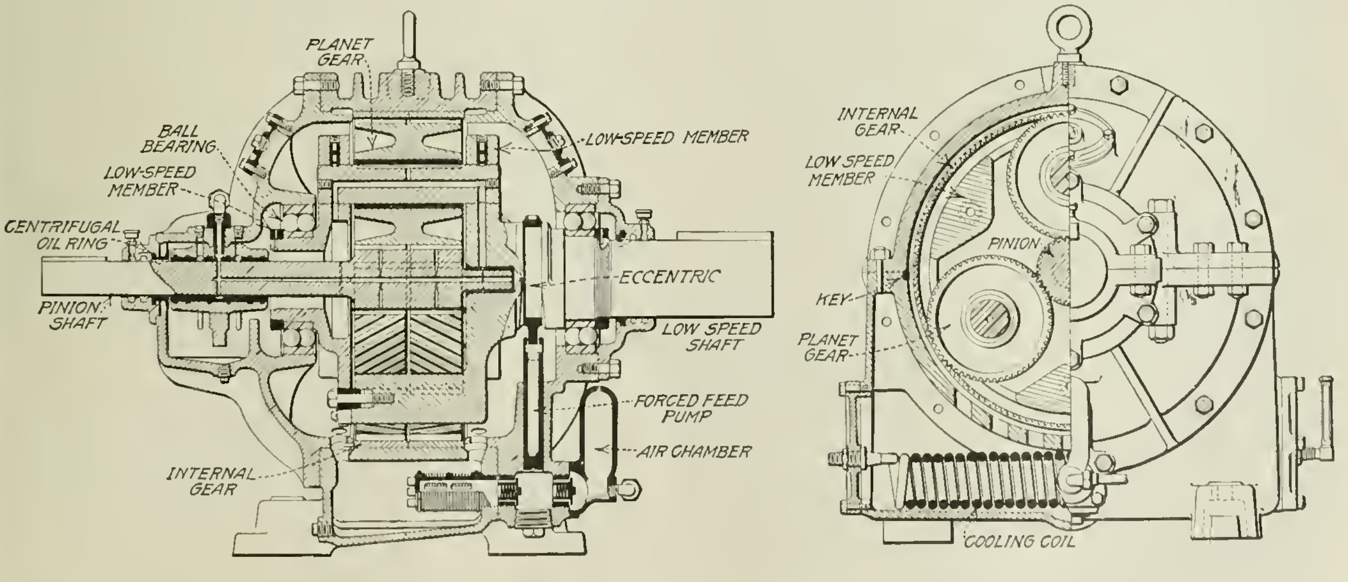

FIG. 4. LONGITUDINAL AND TRANSVERSE CROSS-SECTION OF THE TURBO GEAR

Electric Welding Stops Leaks in Girth Seams

BY ROMEO A. GRISE

To engineers who have experienced trouble with leaks in the first girth seam of return-tubular boilers, the following is of interest. The trouble referred to in this article is leakage due to fire-cracks at the seam over the fire.

IN THE plant to which this article refers there are five 84-in. return-tubular boilers with overhanging fronts, nine 72-in. return-tubular boilers with flush fronts and two water-tube boilers. The boilers that gave the trouble are the 84-in. and that in spite of the fact that the oldest of these five has been in service seven years. None of the other boilers has ever given any trouble at the girth seams.

The first of the troublesome boilers had been in place almost four years before any leakage occurred, and that was so slight at first that when new boilers were needed for extensions it did not influence us against choosing the same type. The fire-cracks through which the leakage passed appeared from the rivet hole to the calking edge. At first only a few were noticed, but as time wore on it was not surprising to find twelve to sixteen cracks on one boiler extending from a point over the fire to about one-quarter way around the shell. Some of the cracks were from one rivet hole to another. Pieces of the plate actually fell out while the boilermakers were calking the edge.

Cause of Leaks Perplexing

The cause of the trouble puzzled us all. Some said it was due to the water; but if that was so, why did we not also have trouble with the 72-in. boilers? One thing seems certain, and that is, the thickness of the metal from which the shell was made had some influence. These boilers are made of $\frac{5}{8}$-in. plate, while the 72-in. boilers are of $\frac{9}{16}$-in. plate. The extra thickness makes some difference when the plate is over a very hot fire, but beyond the possibility of thick plate no one here offers a good reason for the trouble. The material used in making these boilers was not necessarily poor, because all boilers gave the same trouble and no two of them were built at the same time. We do not believe that mud or oil was to blame for the fire-cracks; for while there was just a trace of oil and a little mud did collect in the bottom of the boilers, the same conditions were true for the 72-in. boilers.

It was finally realized that just plain calking would not stop the leaks. It was then decided to try oxyacetylene welding.

The way this was first tried was to weld the plates together solid along the calking edge; but this did not hold, as on absorbing the heat the inside plate would curl up and away from the lap and the weld would break almost immediately. In one joint the strain caused by the cooling of the weld pulled the rivets apart. Then it was decided to take out the rivets where the fire-cracks occurred, "V" out these cracks, weld the plate back to normal again and scarf the edge. After the plate was welded, the rivet holes on the welded plate were drilled and the boiler again riveted just as in the shop. This job seemed to give satisfaction, and the remaining four boilers were similarly repaired. The first boiler ran about six months before it started to leak again, but the other four lasted only a short time; one of them, the last one repaired, held hardly two weeks.

About this time forced draft was used under these boilers, a fact which doubtless did not better conditions, as the fire in the furnace was almost white hot. Still, forced draft was not the cause of the boilers leaking again.

For the next five months we were trying to keep going as best we could. The load was quite heavy, the coal very bad and the draft poor. Those boilers would leak so badly that when the men came on in the morning, there would be a large area on the grates where the fire was dead and the fuel bed water-soaked. Some of the boilers had two or three streams the size of a lead pencil pouring down on the fire. Imagine trying to get up steam under those conditions. It was necessary to have boilermakers on the job every two or three weeks to calk the cracks.

The Electric Welder Is Called In

Finally we got in touch with electric welders who would tackle most any kind of a job and guarantee it to hold. The guarantee was something new to us as the oxyacetylene people would not guarantee their work. As a last resort we decided to give these electric welders a trial. We had everything to gain and nothing to lose; the condition of the boilers meant patching each one of them and possibly having the pressure cut down by the insurance company. And a patch would expose two seams to the fire instead of one, which presented the possibility of twice the trouble and of eventually compelling us to throw out the boilers.

When the electric welder arrived, we had our worst boiler out for him. He looked it over carefully and asked a few questions, then calmly told us he could fix the boiler so it would be tight and would give us a three-year written guarantee. He also gave us as references the owners of two large power plants where he had done similar work. We wrote these people and received encouraging replies.

The process of electric welding required that first the boilermaker chip away all the old stock on the outside of the girth seam till clean metal was reached. When he had chipped away all that was necessary, the welder built up new stock on the plate, bringing it up to its original length and thickness. At the same time that the plate was being built up, it was welded to the other plate at the lap, and when the calking edge was reached the whole seam was welded together.

Where there was much new stock to build up, it was necessary for the boilermaker to chip off the scale of each "layer" as it was applied by the welder. The loose rivets were also welded to the plate without being removed, it being necessary only to chip all around the heads.

For electric power the welder used our regular 110-volt direct current with about 50 amperes. The voltage was cut down to about 20 through a water rheostat. One side of the line was grounded at the switchboard so that the boiler proper formed the other side. On an average job it took the welder between 12 and 14 hours to weld six feet of girth seam.

After this boiler was finished and satisfactorily passed the scrutinizing inspector of the insurance company, we waited a couple of weeks for developments. As the job, however, appeared to hold well and to be as good as guaranteed, we decided to have the remaining four boilers welded.

It is now more than four months since the first boiler was welded, and all five look as good and are as tight as the day they were finished. We feel pretty certain that the welding will hold for the three years and longer.

In the opinion of the writer the success of this job over the oxyacetylene is due to two facts. One is that with oxyacetylene welding the metal is heated over a large area and consequently there are strains when the metal is cooling. In the electric welding the heat is localized with little or no attendant strains due to cooling of the material.

The success of this welding is due also, I believe, to the man doing the work. He must know how to do a first-class job and must use good judgment both as to the amount of stock to be chipped away before he starts welding and as to the thickness of stock applied on each "layer" as he is building upon the old plate.

Maintenance of Electric Elevators

By CHARLES W. NAYLOR
Chief Engineer, Marshall Field & Co., Chicago, Member A. S. M. E.

Cable and brake troubles, iron vs. steel ropes, governor cables, the need of lubrication and kilowatt-hour consumption per car-mile of electric elevators are discussed.

CABLES, as the wire lifting ropes of elevators are called, are the source of one of the two chief elevator troubles. The substitution of steel for iron ropes, which has come about during the last twenty years, has added greatly to the worries of maintenance engineers, for the change has not brought with it all that might be wished for. The more recent machines, with their higher speeds and greater loads, naturally led to the use of new materials without necessarily adding to their reliability. The increased cost of renewals accompanying the use of steel cables is almost enough to condemn them. If the operator would be satisfied to put up with the troublesome stretch of iron ropes, he would be tempted to use them exclusively, but excessive stretching or lengthening of the cables has to be equalized by frequent and tedious readjustments of the limit stops and the compensating devices, particularly where there is only a small overtravel space at the top and bottom of the hatchway. When it is considered that these adjustments must be made for both the car and the counterweights as well as for compensating weights or chains, the engineer will often ask himself, Does it pay?

The harder and stiffer a rope, provided it is flexible enough to suit the carrying sheaves or drums, the more rapidly it crystallizes and breaks. A good quality of iron rope and perhaps a soft-steel cable, may run four or five years on a traction machine, while a hard-steel cable will need replacing in two years or less on account of its greater brittleness. This defect is intensified by the manufacturer making the ropes too hard on the pretense that great strength is needed. This applies equally to all makes of rope.

In spite of the utmost precaution no manufacturer is certain that two batches of rope of the same catalog grade will act alike in service. At any rate the engineer using them knows it by the cost to his employer for renewals. Breakage is liable to occur at any point of the cable running over the drums.

There is another break, which occurs at the shackles on top of the car. It is caused by the flection produced by the cables swinging from side to side. The severe changing torsion set up at this point, because of the tendency of the cable to unwind and rewind on itself due to the set given it when built in the factory, also contributes to the stress at this point. The set in the cable is disturbed by the frequent and great changes in load that accompany the starting and stopping of the car. The strain runs from zero to several thousand pounds and may take place a number of times in each minute that the machine is in operation. The ball-bearing swivel shackle is intended to obviate this trouble, and is successful to a considerable degree.

If a cable runs many years, as was common in the use of elevators years ago, the inner strand will frequently crumble and be broken in small pieces, the cause being largely a lack of interior lubrication in the cable itself. If cables are in use less than three years under average operating conditions, and run in a warm, dry place over generously proportioned drums having a diameter of 60 to 1 for the rope, the lubricant put in the cables by the manufacturer will be sufficient to prevent this cracking. If the life of the cables exceeds this period, and particularly when the cables travel over small sheaves, if the former is of hard material and is used in a cold and damp place, frequent lubrication is necessary. A good penetrating oil or liquid grease is best for this purpose.

Governor ropes or cables are made of vegetable fiber-like hemp or cotton and of steel or iron. They are naturally more flexible than the lifting ropes, but have troubles similar to the larger cables although to a lesser degree. They require internal lubrication only when run in damp places and when in use for unusually long periods. A record kept on manila governor ropes for 15 elevators shows a wearing-out or breaking period varying between 14 and 56 months, with an average life of 37 months.

The second cause of serious trouble in an electric elevator is the brake—and these two troubles, cable and brake, are of more moment than all others combined.

An elevator brake, in many installations, is applied many thousand times every day and must bring a high-speed 40- to 50-hp. motor and a fast-moving elevator car weighing 6000 to 8000 lb. to rest and hold it each time the car is stopped. Of course it is helped to some extent by the dynamic-braking action of the motor, but the real stopping is done by the brake itself. Since the brake has to act so frequently and positively, it must act through a small space, which minimizes the opportunities for adjustments. In fact, it is an extremely difficult task to adjust a brake so that it will work equally well on up and down travel, and particularly with temperature changes that come with frequent use. Brake bands and their lining and the brake wheels or drums, become hot on severe service, rising 75 or 100 deg. F. above the temperature of the surrounding atmosphere.

The lining of the brake band, on which the brunt of the work falls, gives the most trouble. No really good substitute for the usual leather lining has been found, although a number of asbestos and fibrous compounds have been given trials. The old-style wooden blocks with the grain end on did not prove satisfactory.

A brake must set itself smoothly, not too suddenly, and with certainty. Brake slippage, if not too serious, may be anticipated by the skilled operator, except at the top and bottom landing, where there is small pit space. A car must come to the top and bottom landings at normal speed, as otherwise the automatic limit stops interfere with the car reaching the floor.

A good brake lining in easy service may last for years, but in heavy work only a few months. The leathers must be solid and clear of hard spots. Built-up leather in which glue or cement is used, will not last long enough to justify giving it a trial.

CALCULATING THE ENERGY CONSUMPTION

The energy consumption in kilowatt-hours per mile of car travel is best obtained by taking the total readings over a period of not less than eight hours. An ordinary recording watt-hour meter and a revolution counter attached to the main drum or sheave will answer the purpose nicely. The counter must not be attached to the drum periphery, because the speed, often 400 to 500 ft. per min. is too great. A good place to connect on the counter is at the small chain operating the signal lights, if this latter device is used.

There is a movement of the car at the end of its travel that is too small to register a full unit on the counter, but this is absorbed in the total travel when the test is extended over several hours. It is seldom that the recorded revolutions of the counter match evenly with the cable travel, so that a constant must be found and used in multiplying the revolutions to give a correct product in feet or miles.

As explained in a previous article ("Operating Costs of Electric Elevators," Feb. 5 issue) the plant in question contains 91 elevators, 77 being used for passenger service and 14 for freight. Fifty of the passenger cars are of the worm-gear overhead drum type. The others are traction elevators, a few being of the basement type.

The drum machines run 11 to 15 miles per day and the traction elevators, 16 to 20 miles each. The energy consumption of the drum-type elevators is 3.5 to 5.5 kw.-hr. per mile of car travel. No two cars out of the 50 under discussion use exactly the same amount of current, except by accident, and any one car will register differently from one day to another, but the average for any ten cars taken at random, is 4.55 kw.-hr. per car-mile. For the traction machines it is 4.25 kw.-hr. per car-mile. The car speed per minute is greater in the case of the traction machines, but the cars are smaller and lighter. The drum-machine motors are rated at 42 hp. and run at 700 and 850 r.p.m., while the traction-machine motors are 35 hp. at 60 to 65 revolutions.

In a working plant it is not convenient to get the comparative records for up and down travel, and when varying loads in both directions are taken into consideration, there is no good reason for assuming any difference. In the plant under discussion about 40 cars are operated on the basis of 20 for up passengers only and 20 for down travel. These cars run empty in the opposite direction, yet careful and numerous readings fail to show any material difference in the results that are obtained.

Five basement traction machines showing 9.4 miles each per day, average 6.3 kw.-hr. per car-mile. Eight overhead one-to-one traction elevators with 16 landings, running express to the seventh floor, show 17.5 miles each per day and an average of 4.6 kw.-hr. per car-mile. Two overhead drum-type machines with light cars, stopping only at the first, seventh, eighth and ninth floors, travel 16 miles per day on a current consumption of 3.6 kw.-hr. per mile. Forty or more overhead drum-type machines averaging 14.5 miles per day, use 5.1 kw.-hr. per car-mile. The accuracy of all tests on individual machines has been demonstrated by comparing results obtained on two watt-hour meters and further checked by testing the machines in groups of five on a large watt-hour meter.

Carelessness Wrecks Gasoline Plant

Carelessness on the part of a helper in the engine room of the Moon gasoline plant, near Tulsa, Okla., wrecked the building, as shown in the illustration. The explosion was due to two causes. First, one of the compressors exploded, filling the plant with gas; then an inexperienced engineer's helper took it upon himself to stop the engine, and in doing so he made the mistake of pulling a spark-plug connection, which ignited the gas and caused an explosion. Eight men were seriously injured. As shown in illustration, the roof, which was made of corrugated iron, and the sides of the building were partly blown off.

BUILDING WRECKED BY GAS EXPLOSION

SMALL WEIGHTS ON BIG SCALES

BY
M. D. Church

It is occasionally desired to weigh small articles accurately when the only means available is a platform scale designed for weighing hundreds of pounds. By a method outlined herewith, small articles may be weighed on platform scales within 1/100 lb. and often within 1/400 lb. of accuracy.

On most platform scales the 100-lb. weight actually weighs one pound. That is, one pound on the weight pan will balance 100 lb. on the platform. Other scales have ratios of 200: 1 or 50: 1. In any case the ratio can usually be found easily by reading the marks on one of the weights or weighing one or more of them.

Let us assume we have a platform scale capable of weighing up to 600 lb. by half-pounds and that it has a ratio of 100: 1. If it is desired to weigh a small article accurately, place it on the weight pan and run the sliding weight back to zero. Then put sufficient weight of any kind on the platform to raise the beam. Your own weight is usually most convenient. Balance the scales with the sliding weight, and note the reading. Suppose this to be 115½ lb., for example; then remove the article being weighed, say it is a spring, and again balance the scales by sliding the weight on the beam or adding scale weights to the weight pan. Note the reading again, say 153 lb. The weight of the article is (153 — 115½) ÷ 100 = 0.375 lb.

This method can be extended to cover many uses, as for any weight from as small as will tip the beam up to a weight as great as the range of the scale divided by the ratio.

One particular use of this method is for the determination of specific gravity. If we have a specimen of metal, rock or other insoluble substance that will not float, the following method may be used: With a light cord hang the specimen a foot or so below the weight pan and take its weight. Then hold a pail of water so that the specimen is submerged and weigh again. Using the rule, specific gravity equals weight in air divided by loss of weight in water, if a piece of metal weighs 1.43 lb. in the air and 1.225 lb. in water, the specific gravity is 1.43 ÷ (1.43 — 1.225) = 6.97+.

In the case of liquids hang an empty bottle on the scale pan by a cord and balance the scales. Then fill the bottle to a given point with water and find the weight of the water by the method already given. Then fill the bottle to exactly the same point with the liquid to be tested and get the weight of that. The specific gravity of the liquid will be equal to the weight of liquid divided by the weight of water. That is, if the water weighed 2.147 lb. and the weight of an equal volume of a certain kind of oil was 2.042 lb., the specific gravity of the oil would be 2.042 ÷ 2.147 = 0.952.

The idea of using the ratio of the scales applies also to utilizing the scales for counting when the amount of counting to be done does not warrant a special scale. Suppose we have a thousand or so nuts to be counted. Place a box on the scale platform and balance the scales by the sliding weight. Then put the nuts into the box. Again balance the scales by piling nuts on the weight pan. If the ratio of the scales is 100: 1, there will be as many hundreds of nuts in the box as there are nuts on the pan. If accuracy is desired, the final balancing may be done by taking a few nuts out of the box and counting the odd nuts and those on the pan by hand.

When there is much counting to be done, it will be found handy to make a special pan out of a small pie tin and a piece of rod to take the place of the regular pan. It should be made to weigh exactly the same as the regular pan and will hold many more small parts. Such an arrangement will be found handy in any storeroom and will usually pave the way for a regular counting scale.

Industrial Plant Furnishes Street Railway Power

It is often possible for an industrial power plant to find some use for its excess power which will extend the period of the peak load without increasing its magnitude and at the same time materially benefit the new power user. An interesting example of this is the supply of direct current by the Westinghouse Electric and Manufacturing Co. to the Pittsburgh Railways Co. for the operation of its cars in and about East Pittsburgh, Penn. Owing to the tremendous increase in the number of employees at the Westinghouse plant, the present overhead equipment of the street railway was overtaxed for about two hours morning and evening.

To take care of this condition, connections were made between the railway-feeder system and the Westinghouse company's rotary converters in its power house. Since this arrangement has been in operation there has always been plenty of power to move cars at any time and the day's demand upon the industrial power plant has not increased, although its duration has been somewhat lengthened.

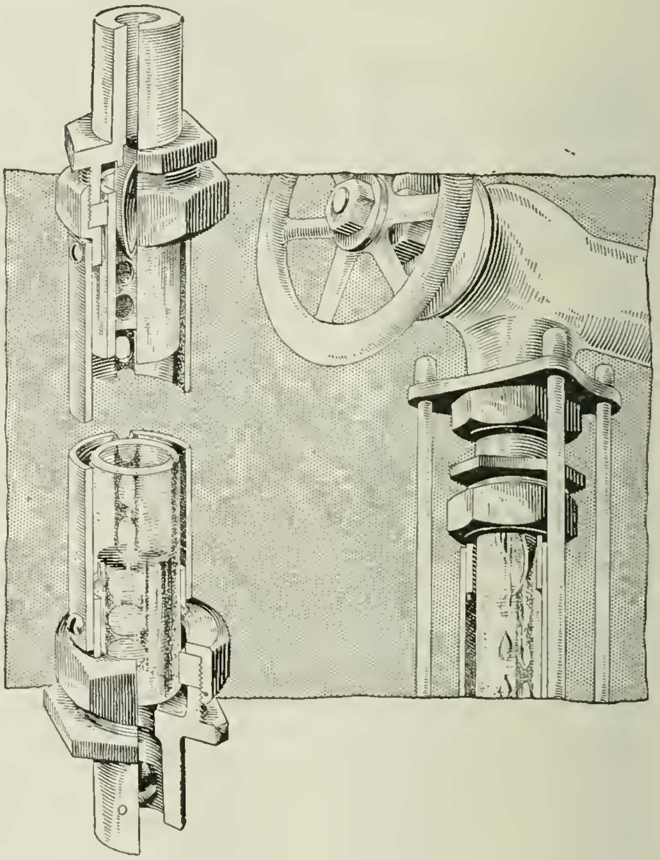
There is no doubt that many industrial companies similarly located with respect to transit lines extending out a considerable distance beyond the railway's last substation could use such a method with great advantage. While the revenue from the sale of power is of course desirable, the principal benefit will be found to be in getting employees to and from work on time, in which an ample supply of power is an important factor.

Ernst Safety Gage-Glass

One of the annoyances of the boiler room is the breaking of water-gage glasses. This is due to several reasons, such as the connections being out of alignment, erosion of the glasses at the upper end, due to the action of steam, cold drafts striking the glass, accidental breakage, etc.

These causes of breakage seem to have been overcome in the Ernst safety-gage glass, manufactured by Ernst & Co., Newark, N. J. The water glass is fitted into a centralizing member composed of an upper and a lower holder, each fitted with a packing nut. To a projection of each a removable metal half frame is secured, which holds the whole rigid. The back of the frame is drilled with ¼-in. holes and three lines of red are painted on the inside of the strip, which causes the water to show red when it is viewed from any direction.

In the upper connection there is a hollow pen-shaped member through which all condensation trickles without touching the glass, which is held tight in the upper and lower members by rubber washers and packing nuts in the regular manner.



DETAIL OF THE ERNST SAFETY GAGE-GLASS

The top and bottom nipples of the centralizing device fit into the regular water-glass connection, the same as the ordinary water glass, but any ordinary packing can be used to keep them steam- and water-tight.

The bottom member of the centralizing device is fitted with a check ball which operates only when the glass breaks, in which case the ball is forced up against its seat, thus preventing the escape of water. As the ball operates in a vertical chamber, which, although containing a ball, has an area equal to that of the opening in the top member, it cannot remain in a closed position. Any glass will fit into the protecting frame, and the complete member takes the place of the ordinary water glass.

The Miracle of the Mass

NORMALLY the mass of the people follow a few leaders. History is the record, page after page, of the doings of the nations under the guidance of a few men. But now and then in the record you come to a story—and it is always a thriller—in which the mass of the people yank their leaders from the head of the procession and move whenever and wherever their whims or their wisdom dictates. Such a page is being written now in the logbook of the world.

Mass movements are the miracles of the day. They are the big surprise. When the war began, our minds ran riot with the expectancy of inventions—of miracles of matter. We awaited the daring developments of wizardry—things wireless, things uncanny.

There have been miracles of matter, of course. In time of peace we would have acclaimed them as marvelous. But we give them a glance and turn with serious interest to the miracles of mass movement. If a chemist came forth now and turned gold into lead, our eyes would still be riveted to the Russian drama where diamonds have become dust, and dust is becoming—what? We look at Germany and Austria. Will the miracles of the mass overcome their own miracles of matter and make ours unnecessary? In England, they tell us, an orderly miracle of the mass is taking place—and in France.

Who doesn't sense the upgathering sweep of it at home? And if your feeling is one akin to fear, is there or isn't there, mingled with it and dominating it, a sense of relief because many of the hampering grips of the old order are passing into history?

It will be an interesting story when it is written by a future Carlyle; and those of us living in the life of it will understand it better when we read it than we do now. Old phrases will come back to us. "Cost Plus" will be one of them. We shall wonder then, not at the miracle of the mass, but at the stark madness of men—we had thought them big men—who played poker openly at a holy moment. The tragedy of it is that the poker players are a minority of what we have come to call our classes—distinctions by professions.

But the mass indignation does not discriminate. By its very nature it cannot discriminate. It is too overwhelming. It is a thing of the heart, not of the head.

The miracle of the mass can wreck us or save us. In all groups there are good and bad, in the moral sense. There are good lawyers and bad lawyers, good employers and bad employers, good engineers and bad engineers, good laborers and bad laborers. If the old classification by professions does not disappear—and that quickly—the outlook is ominous. If the employers stick together *as a class*, the lawyers *as a class*, the industrial workers *as a class*, regardless of the good and evil among them, Heaven help us. But if the upsweeping protest against the poker players of all classes destroys the class distinctions and aligns the good against the bad, then we are saved.

The hope of salvation grows day by day. Our fight against a ruthless autocracy to whom people are pawns has stirred our deepest age-old moral instincts. The sons of most of us are in that fight. Their lives cannot be gambled with by the poker players of any class, and this feeling is permeating the good men of all classes.

What the miracle of the mass will mean to us in this country lies in a large measure in the hands of the good employers. Are they courageous enough to meet their clear duty, to cut loose from an artificial class grouping, and align themselves, *by their acts*, with the good in the new moral grouping?

What will the future Carlyle say of them?

The Boston Turbine Accident

NATURALLY, much interest is centered in the accident to the thirty-five thousand kilowatt horizontal twenty-stage, impulse turbine in the O Street Station of the Boston Elevated Railway Co. The machine was of a type that represents the most advanced in design of single-cylinder turbines of large capacity. With condenser and air pump it represented an investment of about $335,000.

The details of the wreck are told on page 390 of this issue, so there is no need of reiteration here. It seems certain that deflection of the cast-iron diaphragm in the eighteenth stage causing the diaphragm to rub the wheel and release the buckets was the immediate cause of the accident, just as similar deflection of a cast-iron diaphragm in the same stage of this turbine once before stripped the buckets from the wheel.

Considering that the whole low-pressure end, rotor and casing, went to pieces, it is miraculously fortunate that no one was killed or injured.

As pointed out in the article, the question arises as to whether it is advisable to extend the use of steel to the large diaphrams in the lowest stages of these high-capacity machines. The question is one which cannot be finally answered offhand at this time. If in these very large diaphragms it is found that the cast iron is subject to frequent deflection; that the bond between the buckets and the disk and ring of the diaphragm soon weaken; or if these relatively thin disks are likely through any cause foreseen to be subjected to the stresses set up by centrifugal force imposed by accidentally revolving with the shaft—then steel seems advisable unless some means of avoiding these possible troubles with cast iron are found, and this seems possible. It should here be pointed out that the Boston accident is the only case we know of where a diaphragm let down on the shaft.

This Boston accident gives an impressive example to all operating engineers of the value of accurate, decisive and quick judgment while on duty and responsible for turbines in their charge. With wheel speeds up to nearly one thousand feet per second, as in these large machines, the operator must be quick enough either in adjusting the thrust bearing or tripping the machine out of service to avoid longer than momentary rubbing of buckets and diaphragms at this speed. There must be no continued rubbing. That is a vital maxim. The operator must develop with the turbine. The builder and the employer must see to it that he so thoroughly understands how the machines under his care are put together that he can in effect look through the casing and see every detail, gage every clearance and anticipate the effect of this and that happening upon the safety and economy of the machine. The operator has the right to demand that every reasonable facility be available to him to know his machine. For this reason the policy of any builder to make it difficult to get drawings or photographs that would assist the operator in better knowing his machine is a policy that has no place in modern power-plant engineering, regardless of commercial considerations. All builders maintain corps of men for the very purpose of providing such information to operators. But that is not enough; the operator must get it and use it.

The accident at Boston is simply an unfortunate one in the development of the art. Because the turbine is the first of the particular type that it represents does not mean that there is anything fundamentally wrong in its design. We believe the design is safe. It is the opinion of all users of large-capacity machines whom we know personally that this design is safe. There are millions of kilowatts of such types of machines on order for large plants the country over. The accident at Boston is, perhaps, the most momentous in turbine history, and likely it will in time have done more good for turbine development than any other factor one can name.

What Is the Capacity of a Turbine?

IF YOU order a ten-, a twenty-, or a fifty-thousand kilowatt turbine and if, when installed, it carries a water-box load of just the capacity specified, but will not carry a thousand- or two-thousand kilowatt load swing above that amount without speed reduction and decrease in cycles—if these are the conditions, have you got a ten-, a twenty- or a fifty-thousand kilowatt machine? If the load was such as to swing one or two thousand kilowatts above ten, or twenty or fifty thousand, would you report the load to the public-service commission, if a public utility, as the average or as the peak maximum?

Of course these points have been quite thoroughly thrashed out, but all engineers do not agree. The disputes about machine capacity led to "max. rating," as engineers like to call it. That is, the greatest load a machine will carry with specified speed is the capacity of that machine. Technically, that seems reasonable. But the early conservatism of builders in rating their machines got engineers into the habit of expecting more than rating from them.

We thought that this question of rating had been settled, but there are still some wrinkles in it that have not been ironed out to the satisfaction of some folks. In fact, it is probable that recent events will open up the whole question anew, notwithstanding the set opinions of authoritative persons. Obviously, three factors influence the capacity of the machine; namely the pressure at the throttle, or better, the pressure at the first stage, the superheat and the vacuum. In disputes about the capacity of any particular turbine at some particular time—as, for example, on load swings—one naturally inquires what the steam and vacuum conditions were at the time. Were these below what the turbine required in order to develop the necessary capacity? If so, the cause is not in the turbine and the purchaser is at fault. If these conditions were normal, that is, as specified in the guarantee, and the swings, whatever they may be, five, six or seven per cent. of the turbine rating could not be carried, then is anyone at fault? Who is going to say where the limit is in this ability of a turbine to carry swings above the rated capacity? Who will say that the turbine should not be expected to carry any swing above its rated load? What is the consensus of opinion? One requisite is clear as concerns the purchaser—he should have a record of load, steam pressure at the throttle, superheat and vacuum as his evidence in event of dispute. Frank expressions now would clear the air, and *Power* welcomes such expressions.

Ash-Handling Apparatus

IN OUR issue of February 5 appeared an article by Herbert E. Birch entitled "Buying an Ash-Handling System." The editor who handled it did not know that the author was the consulting engineer of a manufacturer of conveyors of the bucket or skip type, and even if he had would not have considered that fact a disqualification. It is to specialists of this kind that we must turn for the latest and best information upon their respective subjects. We do not intentionally pay such authors for briefs of their cases in favor of their own apparatus nor permit them to go outside of engineering grounds in criticizing the apparatus of their competitors.

Letters from several manufacturers of apparatus of other types and their representatives express surprise that *Power* should have printed an article which attacks so viciously their type of apparatus. The "attack" was so well camouflaged as not to have been apparent to a disinterested editor, and its viciousness appears to be more evident to the minds of the victims of the supposed attack than to the less-interested reader.

The article stands simply for what it is, a presentment, by a man who is identified in a consulting capacity with one type of ash-conveying machinery, of some of the points to be considered in selecting an installation. It bears nobody's indorsement and is open to criticism, denial, refutation and reversal if anybody has a case against it and the will to state it. We have no interest or predilection in the matter and invite the fullest and freest discussion upon any statement which the author has made or any suggestion which he has advanced, not only from makers of the apparatus criticized, but from all our readers, especially those who have had experience with ash-handling apparatus of any kind.

Incidentally, we have an apparatus of one of the types criticized in our own plant.

Correspondence

The Conservation of Fuel

There have been some mighty good articles on fuel conservation published in various papers, but it seems to me that the good advice, in general, is directed at the operating engineers and boiler-room attendants. Without a doubt there could be enormous savings effected in some plants, but on the whole the best the operator can do is to operate the plant of which he has charge at the highest degree of economy possible under the given conditions. As a rule, the highest degree of economy cannot be brought about by the operator alone; some good sound judgment has to be exercised by the purchasing department as well. For instance, there are plants where at least 40 per cent. of the fuel burned goes for live-steam heating, yet such plants are operated condensing, with motor-driven auxiliaries and not enough steam-driven noncondensing units to even bring the temperature of the feed water up to 212 deg., to say nothing of heating buildings.

If the Government wishes to conserve the coal supply, it should request all municipalities and private corporations that contemplate building power plants or making changes, to submit full plans of the work and detailed information regarding it, to their engineering department for inspection. This would do away with the jumping-at-conclusions method and make the purchasing man sit up and take notice. **Louis P. Allen.**

Johnson City, N. Y.

A Talk to Firemen on Saving Coal

In the Jan. 22 issue of *Power*, there appeared an article on the conservation of coal which I am sure appeals to all who have any intimate contact with this, at present, scarce and costly commodity. That firing is an art learned only through experience is a fact that no engineer will deny; yet how small is the percentage of men who use their brains with their efforts when shoveling coal into furnaces.

Supervision of the coal pile by chief engineers is something which the average fireman resents, and often leads to the frequent changes that are made in the fireroom.

Mr. Bromley states that employers need educating as well as employees. While this is true, it does not get at the real seat of the trouble. To analyze the situation it is necessary to go back to the inception of the plant, to the point where it was planned. In many cases I think it will be found that the boiler plant, as well as all other machinery, was laid out largely according to the views of an architect. Boilers, boiler settings, grates, etc., agreeing to some arbitrary standard were installed with little regard to conditions as they would apply after completion. The result is that after the engineering staff has been placed in charge it must make the best of it.

The hints given for the handling of the different kinds of fires I think are good. They are practical. From experience I have found that the dumping grate is far more desirable than either the stationary or shaking grate. It seems, too, that the hand-fired stokers now being offered have a good field.

As regards the excessive ash content of the hard coals now available, most any engineer will agree that Mr. Bromley's statement is correct. Under these conditions, then, conserving the coal supply is extremely difficult, and when one considers that the cost of coal is about 70 per cent. higher this winter and that more of it has to be burned to get the required results, it is almost beyond human effort to economize in any plant where care is always used to see that only the required amount of coal is used to economically carry the load.

I should like to see a discussion in *Power* as to the probable savings to be gained by changing grates and ashpit levels under boilers built 20 years ago where the heating surface is approximately 30 in. above the grate, to the heights of 60 or 72 in. as advocated in Mr. Bromley's article. It seems that the time is ripe for a discussion on the relative merits of what is gained by keeping the water in the boiler at a certain level under all conditions of load, also if it is preferable to return the water of condensation to a storage tank or to pipe it to a governor through which it will be pumped to the boiler after passing through a heater and meter. **H. H. Burley.**

Brooklyn, N. Y.

Climbing a Smoke-Stack

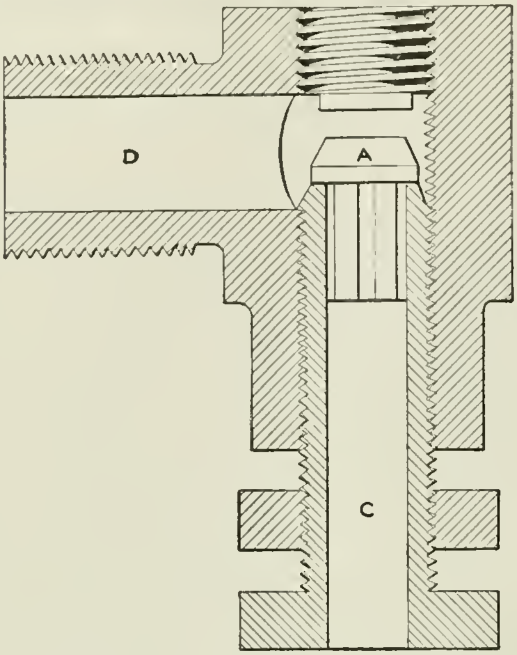
In connection with the letter by D. R. Hibbs in the issue of Jan. 1, page 24, regarding climbing smokestacks not fitted with ladders, the following may be of interest. A stack painter of my acquaintance uses three slings made of three-quarter inch rope with one end made into an eye; two of the slings have stirrups at the other end and the third has a long loose end. When climbing a stack, the slings are passed around the stack with the rope drawn through the eye, the feet being placed one in each stirrup, and the free end of the third sling drawn around the painter's waist and one end of a light hand line made fast to the waist line convenient to the painter's hand. In climbing the stack, the waistline sling is placed around the stack above the stirrup lines and is raised by drawing it back and forth around the stack; the others are then raised the same way, one at a time.

When the painter reaches the top of the stack, he hauls up the paint bucket and brush with the hand line, hangs it on the waist line with a hook and paints the stack above the slings. Moving the slings around and down the stack, he paints the whole stack as he goes down. This man once painted a stack seven feet in diameter and one hundred feet high in eight hours from the time he started to climb up.

Ringwood Manor, N. J. **A. A. Blanchard.**

Improved Snifting Valve

Snifting valves are a rather despised and neglected pump accessory, but their utility is above question. Even slow-running boiler-feed pumps with a long stroke and a perceptible pause at each stroke have such valves fitted, although they are less necessary than on high-speed pumps, and there are many such, which must employ means to cushion the blow. They are usually fitted between the suction and delivery valves to admit air on the suction stroke, cushioning the blow of the plunger and seating the valves without shock; and there is a difference in running with and without them, especially under variable speed.



AUTOMATIC AIR INLET FOR PUMP SUCTION

In the pulsometer type of pump the snifting valves are of more than ordinary importance, and unless they are correctly adjusted, the efficiency of the pump (never very great) is much impaired. The air has a special function in this type of pump in that it acts as a nonconducting layer between the steam and the water. Air being a bad heat conductor, heavier than steam and lighter than water, admirably fills the necessary conditions. The quantity of water delivered is seriously affected by imperfect adjustment of the snifting valves.

The usual fitting is in most cases leaky, the seat and valve get battered so that at each delivery stroke it leaks water, to the annoyance of the engineer, for the type of fitting usually employed is of a cheap character of soft brass, wears rapidly and is tolerated as a sort of necessary evil. Its function is to admit air and close against the escape of water, and while it does the former whatever condition it may be in, it often fails to perform the latter office. Retruing the seat is difficult, the fitting being of small size, while the screw adjustment for lift becomes slack after short service.

The improved valve illustrated was designed by a marine engineer now in charge of a shop making high-grade pumps, and it has had several years' trial with entire satisfaction. The chief feature of the design is a means of adjustment which controls the valve lift. The body of the valve consists of a hard-brass casting *D* fitted with an adjustable valve seat *C* held in the desired position by the locknut shown and a valve *A* made of hard bronze.

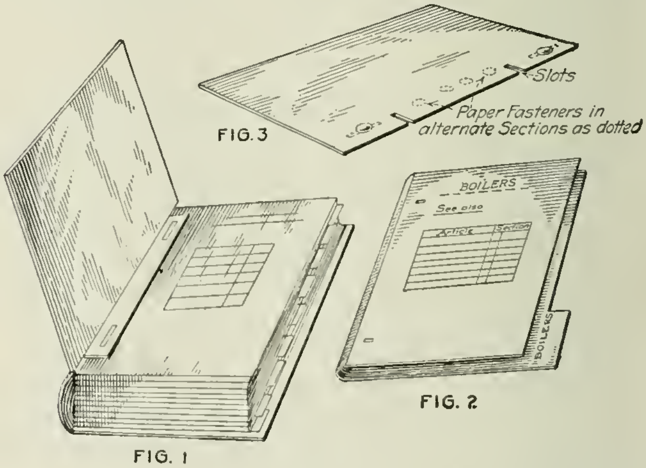
It will be seen that the machining is easy as one hole is drilled through the body and tapped out and the other, at right angles, breaks into the first. The adjustment for valve lift is by means of the portion of *C*, which may be screwed up so valve *A* is close to the stop or as far down as desired. Retruing the valve seat is done in a few minutes wherever that becomes necessary by the withdrawal of *C*. There is nothing to go wrong; it is a rational design for which credit is due to its originator, for although an inversion of ordinary practice, it needs only to be seen to be appreciated.

A. L. **Haas.**

London, England.

Binder for Detached Pages

Readers of *Power* may be interested in the following description of a binder for keeping articles from periodicals in a handy form for reference. A standard *Power* binder is used with manila folders cut and folded as shown (Fig. 2) for each section subject and held in place by the binder strips. Pages from periodicals are clipped together for each section with standard paper fasteners, the edges trimmed and slots cut in the inner edge to pass the binder strips. These are then inserted in their respective folders and the whole binding tightened up in the usual way. The paper fasteners securing the articles in each section should be "staggered," in order to even up the thickness of the binding. To insert new articles, any section can be readily removed from its folder without disturbing those on either side.



FIGS. 1 TO 3. LOOSE-LEAF BINDER FOR MAGAZINE PAGES
Fig. 1—The units all assembled. Fig. 2—One of the manila folders. Fig. 3—Pages clipped together ready to file.

When there are articles relating to different subjects, overlapping or on the same page, the pages are filed under one section or title and reference is made to the other article on the front of its particular section folder in a ruled space for that purpose. I have found it most convenient to have about fourteen section folders in each binder with the marginal title tabs 1¾ in. long in two courses making seven in the length of the folder.

Typical section titles are "Boiler Construction," "Scale and Corrosion," "Boiler Setting," etc., and the number of pages in any section, extending over a period of five years, varies between ten and forty, so that it is easy to refer to the particular information required; and as long as there is room, any article that has any item of interest is inserted and the items marked. Such an adjustable post binder, of a size to take standard pages, and fitted with manila folders ruled and cut for marginal title tabs and having suitable detachable clips for holding the articles in each section and securing them to the binder, would, in my opinion, be of great value to engineers who wish to keep only one or two articles out of any periodical. Couldn't someone get out a binder designed along these lines?

Montreal, Que., Canada. F. A. COMBE.

Helping Out a Worn Compressor

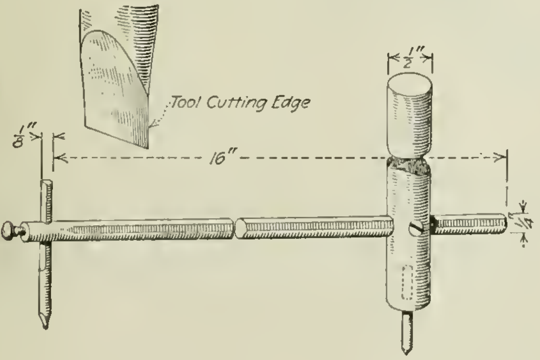
On taking charge of this plant I found the compressor supplying air to the Diesel engines so badly worn both in the valves and piston-packing rings that it was impossible to keep up the required pressure of 75 atmospheres. It was also impossible to get repairs within a reasonable time, therefore it was necessary to do something to overcome the trouble temporarily. The compressor seemed to be blowing back almost half of the air that was drawn in at the suction stroke so I connected a swing-check valve on the air intake and it worked "beautifully"; in a few minutes the air pressure increased from 45 to 80 atmospheres. That gives us a surplus, and we get rid of it by turning the check valve part way over so that it stays open late, allowing some air to escape.

The compressors are of an old two-stage, single-acting type and it is not likely that there are many of this type in service, but the idea may help someone get by while it is so hard to get repairs promptly.

Austin, Texas. F. C. WILLIAMS.

Cutter for Round Gaskets

The illustration shows a simple and easily made device for cutting round gaskets rapidly and accurately of any size within its capacity, from sheet packing. The saving in time is most pronounced when a number of gaskets of the same size are wanted, and it is only necessary to set the cutter once for the diameter desired. It is constructed along the same lines as a beam compass. The main bar, or beam, made from ¼-in. cold-rolled steel rod, is ground flat on one side on an emery wheel to give a good bearing for the setscrew.



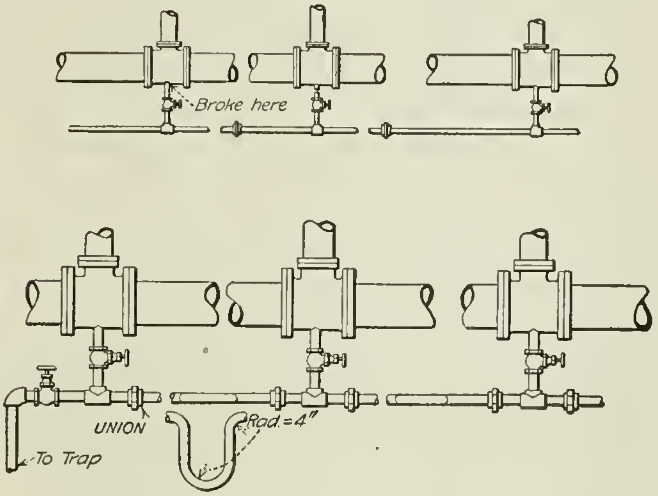
ADJUSTABLE CUTTER FOR GASKETS AND WASHERS

The center point in the handle is made from a broken twist drill of small diameter ground to a needle point. For the cutter use is made of another broken drill about ⅛ in. diameter flattened slightly on an emery wheel, as in the case of the main bar, to give the binding screw a good grip. The cutting end is ground V-shaped and sharp and given a fine edge on an oilstone.

Readville, Mass. H. M. NICHOLS.

How Not To Connect Drain Pipes

The drain line of a header was attached rigidly, as shown in the upper part of the illustration, and there was no chance for expansion, so it broke one of the nipples off one day and shut the plant down, proving that it was not designed rightly. I had some bends made and put in, after which there were no more leaks as there was plenty of chance for expansion; besides, whenever it was necessary to put a new gasket in any part of the header, the flanges could be spread without disconnecting the drain line.



OLD AND NEW HEADER DRAIN LINE

Northport, Wash. N. C. GLEASON.

Taper for Flash Test of Oil

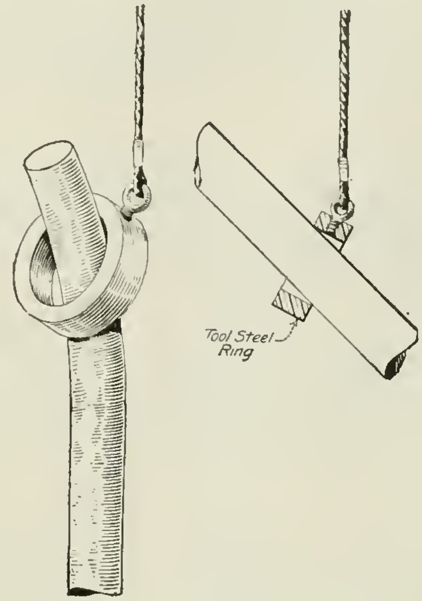
In applying the open-cup oil test for determining the flash and burning points of lubricating oils, a "lighted taper" is passed over the cup about a quarter of an inch above the surface of the oil, but a lighted string or broom straw, as usually suggested, is unsatisfactory to manipulate because embers may drop into the oil and spoil the accuracy of the determination of the flash point at least.

I have found that an old bunsen burner or chemical blowpipe connected to the gas supply with rubber tubing will give a fine gas jet which can be easily regulated to obtain the desired test flame. The blowpipe should be held so that the flame is in a horizontal plane. A cruder but effective "taper" can be made by inserting into the end of the gas tubing a piece of small tubular porcelain such as is used to support crucibles above bunsen burners. WILLIAM J. DANA.

Baltimore, Md.

Ring for Hoisting Wire

The steel ring shown is a time saver and gives a perfect grip when hoisting wires up to elevated lines inside or outdoors, where the common knot frequently slips. This ring can be used to raise any wire that is stiff enough not to be bent by the strain of the ring; the heavier the wire the more positive the grip. The ring is made of tool steel, with sharp edges and hardened.



HOISTING RING FOR CABLES

Valve Opening Against Pressure

The damage and delay that can be caused by incompetent men handling machinery was demonstrated the other day in a plant where several elevator pumps take their suction supply at 80 lb. pressure from an elevated tank.

A helper, when ordered to start one of these pumps, found that the globe valve on the suction line was hard to open (on account of the pressure), but proceeded to apply force to it until the stem was broken, instead of first equalizing the pressure on the two sides by means of the bypass as he should have done. The pump was out of service for several days, and considerable expense was occasioned by this lack of knowledge on the part of the operator. W. T. **Osborn.**

Newark, N. J.

Resistivity of Copper

Certain formulas that are used for figuring the size of wire to transmit a certain current a given distance with a specified voltage drop read: Circ.mils $= 10.6 \times 2 \times D \times I \div E_d$. Others read: Circ.mils $= 11 \times 2 \times D \times I \div E_d$, where D equals the length of the circuit one way in feet, I the current and E_d the volts drop in the circuit. Note that the formulas are the same except that the constant 10.6 is used in one and 11 in the other. Why these two different values are used may be explained thus: The values 10.6 and 11 respectively represent the resistance per circular-mil-foot of copper. The resistance of copper or any metal increases with its temperature and varies with the purity of the metal; hence a circular-mil-foot of copper will have a resistance of exactly 10.6 ohms only at some certain temperature and when the metal is of a certain degree of purity. For example, copper of 98 per cent. conductivity has, at 68 deg. F., a resistance of almost exactly 10.6 ohms per circular-mil-foot. At a temperature of 86 deg. F., copper of 98 per cent. conductivity has a resistance of 11 ohms per circular-mil-foot.

It is evident, then, that the value 10.6 may be entirely correct for a certain condition and the value 11 ohms also correct for another condition. However, in making wiring calculations there are so many indeterminate factors that affect the problem that it is a waste of time to endeavor to attain great accuracy. The value D (distance) in the foregoing formulas can ordinarily not be determined within 10 per cent. and the value I (amperes) is usually also an approximation. For these reasons it is believed that, on the whole, the result will be as accurate if the value 11 is used instead of 10.6. Furthermore, the value 11 is easier to remember and can be handled with less labor. T. H. **Nash.**

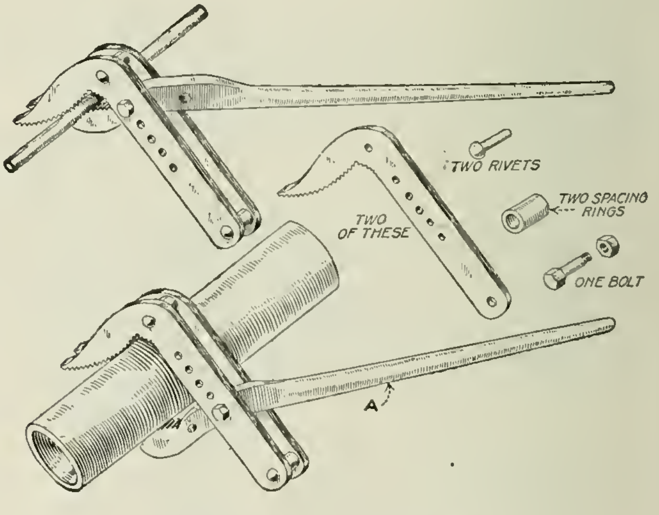
Pipe Wrench for Many Sizes

Having the bar *A* originally belonging to a large pipe wrench "kicking around" the power house, I decided to utilize it and avoid the expense of buying a new one. The upper jaws are home-made. They are different from the regular ones and in my opinion are better for some work and have a larger capacity or adjustment for different pipe sizes. The holes are for adjusting for various sizes of pipes. The two parts of the jaw are held together by two rivets with two spacing rings to keep the jaws the right distance apart. The construction is easily understood. J. A. **Lucas.**



ADJUSTABLE PIPE WRENCH

When you save and buy War-Saving Stamps, you help to make the world safe for democracy and at the same time make your financial future safe for yourself.

Inquiries of General Interest

Limitation of Size of Safety Valves—Why are not spring-loaded safety valves made larger than 4½ in.?
M. F.

When safety valves are larger than 4½ in., unequal expansion of the parts from temperatures imparted by the steam is likely to cause leakage or derangement.

Dead-Weighted Safety Valve—What is a dead-weighted safety valve and what advantage has it over a weighted-lever safety valve?
E. W.

A dead-weighted safety valve is one that is held to its seat by the dead weight of the valve and generally an additional weight, consisting of a cast-iron ball mounted centrally on the valve spindle. The principal advantage of this form of valve over a lever safety valve is that it cannot be so easily overloaded.

Auxiliary Valve on Single Steam Pump—Why is it necessary to provide an auxiliary steam valve on a single-cylinder steam pump?
J. R. S.

Proper movement of the main valve cannot be derived from a positive connection to the piston rod, as the steam port would be closed gradually toward the end of the stroke, and although the stroke might be completed, there would be no movement of the valve appropriate for reversal of the stroke. Hence the necessity of an auxiliary valve to effect movement of the main valve.

Rotary Converter Hunting—What are the causes of a rotary converter hunting and how are they remedied?
W. E. A.

The causes of a rotary converter hunting may be divided into two classes, mechanical and electrical. Mechanical causes may be present when reciprocating engines are used to drive the generators, due to the turning effort exerted on the crankpin not being uniform at all parts of the stroke, causing momentary variations in the engine's speed during each revolution. The momentary variations in engine speed cause variations in voltage and frequency of the generator which are transmitted to the converter and cause the machine to hunt. This cause may be remedied by using a heavier flywheel on the engine, or a governor that will not respond to these momentary variations. This trouble can also be alleviated by placing a damping winding, similar to the copper structure on the rotor of a squirrel-cage motor, in the pole faces. The electrical causes are excess drop in voltage due to the transmission line being overloaded, and also to the lack of dampers in the pole faces of the converter; the remedy in this case is obvious.

Hot-Water Supply in Conjunction with Hot-Water Heating—What are the objections, if any, of obtaining a hot-water supply out of the boiler of a gravity hot-water heating system?
G. H. J.

For heating purposes the temperature of the water would need to be adapted to the variable requirements of the heating apparatus and thereby may be unsuitable for the hot-water supply. Another objection is that drafts of water thus made from the heating system would need to be replenished by a supply of cold water that would impair the operation of the heating system, and the sudden changes of temperature would have a tendency to warp and crack the boiler. If it is desired to dispense with a separate fire for obtaining a hot-water supply, it is better to heat the water by means of a water-back or pipe coil placed in the firebox of the heating boiler. Although this may reduce the size of the boiler firebox and interfere to some extent with the capacity of the heating apparatus and economy of fuel, these objections may be compensated by greater convenience and economy in operation of a single fire for the heating apparatus and a hot-water supply.

Requirements and Appointments of Fire Pumps—What are the leading differences between fire pumps and standard pumps?
W. F. C.

Fire pumps are designed with special consideration as to reliability and durability. The valve area must be larger than that of standard pumps, as the demand for water may at any time be in excess of the rating, and the pump can then be run at a very high speed even if the operation may be regarded as unsatisfactory in an ordinary pump. A fire pump should be strong, rustproof and reliable and one that any inexperienced man, who may be excited and in a hurry, could start up instantly without doing any damage and should be provided with cushioning sufficient to prevent damage from pounding when the pump discharges against only atmospheric pressure, as from sudden breaking of a hose or discharge connection near the pump.

Closing Cracks in Brick Settings—What is the best material for pointing the cracks in brickwork of boiler settings?
J. W. R.

Cracks develop from expansion and contraction, and once a crack forms, it will open wider from continued use of the boiler, as small pieces of the wall material fall into the opening with each contraction and, when reëxpansion occurs, these particles and the jagged fracture prevent the joint from closing as tight as it was at the time of the previous expansion. Hence for keeping a crack closed it is necessary to close the opening with an elastic material or cover the crack with a material that will adapt itself to increase of its width. A good plan is to fill the opening with dry asbestos cement, point the outside with ordinary lime mortar for holding the asbestos cement in place, and if serious objection is believed to result from renewal of the cracks, the leakage can be stopped by covering the openings with strips of muslin pasted on the outside of the wall with a good flour paste. The muslin strips should be thoroughly sized with the paste on both sides and applied when the openings are widest, which for most cracks will be when the walls are cold.

Required Size of Duplex Boiler-Feed Pump—What size of duplex boiler-feed pump would be suitable for boilers rated at 450 hp.?
N. H.

To meet emergencies boilers are likely to be forced to deliver one-third more than their rated capacities, and in case of low water at such times, the delivery capacity of the feed pump should be at least double the rate of evaporation. To meet these conditions, without operating the pump beyond the speed proper for a pump in regular service, the regular service capacity needs to be about three times the steady requirement of the boilers when operated at their rated capacity. Allowing the rating to be equivalent to an evaporation of 30 lb. of water per boiler horsepower per hour, the feed pump should be of size suitable for a delivery in regular service at the rate of $450 \times 30 \times 3 = 40{,}500$ lb. of water per hour, or make a displacement equivalent to $40{,}500 \div (60 \times 8.33) = 81$ gal. $= 81 \times 231$ or 18,711 cu.in. per min. Allowing 6 in. stroke, and for maximum rate of delivery a piston speed of 65 ft. = 780 in. per min. (which will be the piston speed for each side of the pump), the pump would make $780 \div (2 \times 6) = 65$ revolutions, or $65 \times 4 = 260$ single strokes per minute; and neglecting the reduction of plunger area due to piston rods, each plunger area would need to be $18{,}711 \div (2 \times 780) = 11.99$ sq.in., which corresponds to about 3⅞ in. diameter. The usual commercial size of duplex pump coming nearest to the above would be 6 × 4 × 6 in.; that is, 6-in. diameter steam cylinders, 4-in. diameter water cylinders and 6-in. stroke.

Economy of Refrigerating Power Plants*

By VICTOR J. AZBE

Résumé of the various factors entering into economy of a refrigerating or ice-making plant. The boiler room, prime mover, auxiliaries and condenser and suction pressures are considered.

WHILE power plants are generally wasteful, the average refrigerating plant is especially so, by reason of the many factors that enter into the ultimate economy. It is generally accepted that five to six tons of ice is produced per ton of coal, but more often only one to two tons is obtained, and to find an ice plant where a saving as great as 50 per cent. could be made is quite common. Some of this loss is due to the improper equipment and improperly proportioned plants, but most of it is due to the fact that good refrigerating power-plant engineers are scarce.

Table 1 shows what a good operating engineer in a plant can do over a mediocre man. It is evident that the chief problem of the mechanical and refrigerating engineer is to develop the proper caliber of power-plant operator. A large percentage of the total loss is ordinarily found in the boiler room, due to either improperly selecting or burning the fuel. Close attention to CO_2 is necessary and seldom exercised. Proper installation of boilers and such damper arrangement that regulation at all loads can be maintained, are important factors.

TABLE I. RESULTS OBTAINED BY TWO ENGINEERS IN THE SAME PLANT WITH THE SAME EQUIPMENT

Tons of Ice per Ton of 10,000 B.T.U. Fuel

	1916	1917	Improvement, 1917 Per Cent.
March	2.88	5.08	76.7
April	3.64	5.02	37.7

August	4.32	5.48	26.7
September	4.06	5.21	28.3
October	3.96	5.35	35.1

Simple steam-driven ice plant. Distilled water can ice. In addition storage to the extent of 150,000 cu ft was maintained with average atmospheric temperature of 90 deg. F., for which no correction was made.

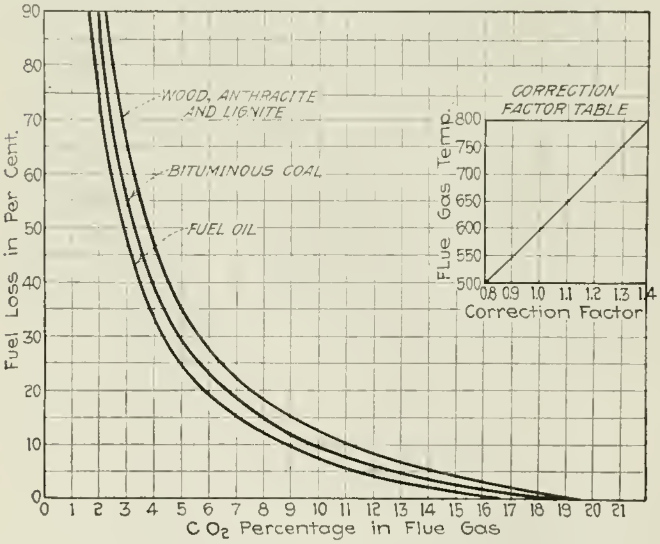

FIG 1. LOSS OF FUEL DUE TO EXCESS AIR WITH VARIOUS CO_2 PERCENTAGES

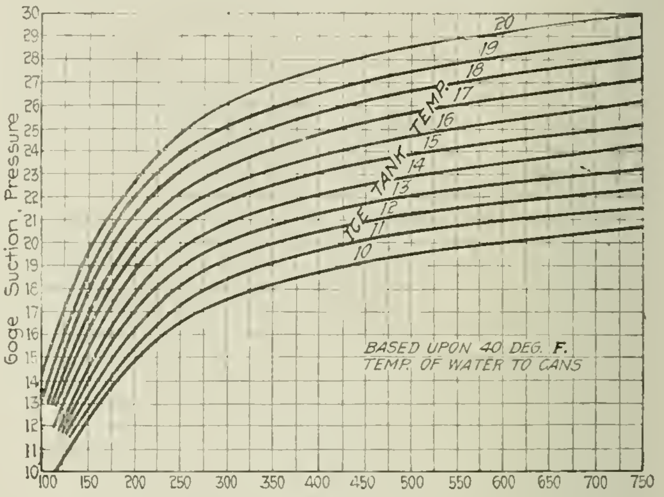
Fig. 1 gives the loss of fuel with different percentages of CO_2 in the flue gases. Table II gives the loss due to carbon monoxide. It must be remembered that CO is not the only loss when there are smoke and incomplete combustion. There may be other gases escaping, having an equally great or greater content of latent heat that becomes unavailable.

In the boiler room close attention must be paid to baffling, gas velocity and cleanliness of heating surface, both internally and externally. These factors have an important bearing on flue-gas temperature, which is all-important when it comes to boiler efficiency.

Average relative values of various fuels are given in Table III. Wood and lignite have been somewhat discredited by being burned under improper conditions and by men unfamiliar with their peculiarities. At present many a plant in this country now burning oil or coal could change with profit to lignite or wood fuel. The data given in the table are conservative and should be obtained in any plant properly equipped and operated.



Linear Length of $1\frac{1}{4}$-in. Pipe per Ton of Ice

FIG. 2. RELATION OF LENGTH OF PIPE PER TON OF ICE TO SUCTION PRESSURE

Few plants operate on a discharge pressure as low as it should be. The condenser may be of improper design, improperly operated or filled with air. There may be insufficient water or poor water distribution, and the surface may be dirty. The condenser pressure should correspond to a temperature of 5 deg. F. above that of the cooling water leaving the condenser. The temperature of the ammonia liquid leaving the condenser should also be close to

---

*Abstract of paper read before the St. Louis Associated Engineering Societies.

the temperature of the coolest water and should pass to the evaporating coils through an insulated receiver and piping by some other way than a hot engine room. Where very cold water is available, a jacketed receiver is desirable. Flooded condensers, however desirable, are greatly misunderstood, and in some plants actually poorer results are obtained than could be expected with the ordinary atmospheric type.

Suction pressure is even more important than condenser pressure, but in spite of this far less understood. Few operating men will take advantage of higher suction pressures at lower loads. Plants actually can be found that in winter operate with suction pressures ten pounds lower than in summer. By increasing the suction pressure to correspond with the lower output, as much as 30 to 50 per cent. in power could at times be saved. Plants should be designed so that high-temperature work can be done at high pressures and in such a way that one or two low-temperature rooms will not spoil the economy of the whole plant. The importance of proper suction and condenser pressures may be realized when it is stated that every ten-pound reduction in ammonia condenser pressure represents about 5 per cent. saving, and every single pound increase in suction pressure represents 2½ per cent. saving. If the length of pipe in the tank is known, Fig. 2 will' give the suction pressure to be expected; Fig. 3 is more complete as it also includes storage refrigeration.

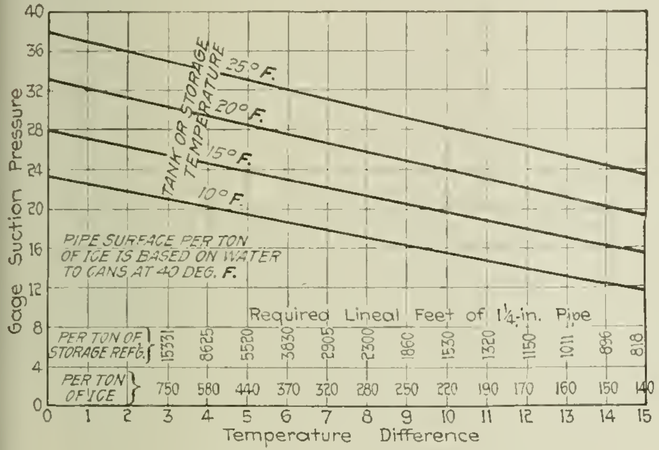

FIG 3. LENGTH OF PIPE FOR VARIOUS TEMPERATURES TO OBTAIN CERTAIN SUCTION PRESSURES

It is known that the power required per ton of refrigeration increases rapidly as the suction pressure decreases. It is also known that the load on the engine decreases with the suction pressure, which in turn tends to increase the steam consumption per horsepower developed. Thus low suction pressure not only increases the power per unit of refrigeration, but also decreases the economy of developing this power. The variation is shown in Fig. 4.

TABLE III. RELATIVE VALUES OF FUELS AND ICE PRODUCTION PER UNIT OF FUEL IN ECONOMICAL PLANTS

	Equiv. Evap per Lb.	Equiv. Cost Not Considering Relative Labor Per Ton	Tons of Ice per Unit of Fuel Simple Non-Cond Plant Tons per Ton	Comp Cond Plant Tons per Ton

		Per 1,000 Cu.Ft.	Tons per 1,000 Cu.Ft.	Tons per 1,000 Cu.Ft.
Natural gas, 1,000 B.t.u.		$0.145	0.26	0.45

Expected production at about 15 lb. suction pressure and 185 lb. condenser pressure.

A serious loss in many plants is uneconomical auxiliaries. There are plants in which the auxiliary steam consumption is equal to or even greater than the steam consumption of the main units, and to further complicate the problem this factor is commonly accepted offhand as not at all serious.

As far as wastefulness is concerned, the duplex steam pump is the champion of them all. Its wastefulness becomes especially great when operated at a low rate of speed. The logical auxiliary unit is a properly designed centrifugal pump of variable speed and driven by power generated initially in an economical unit.

When designing a plant, a careful analysis must be made as to the number and size of auxiliaries. From the economic standpoint they might better be too small than too large. The former can be forced, while the over-large auxiliary is liable to excessive consumption of power or steam.

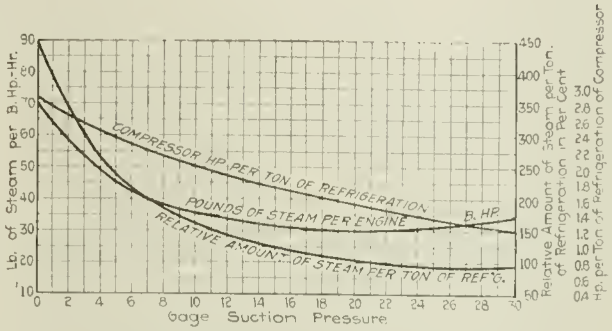

FIG 4. VARIATION OF ECONOMY WITH SUCTION PRESSURE, INCLUDING BOTH ENGINE AND COMPRESSOR

To state that the economy of a properly operated plant, as far as ice per unit of fuel is concerned, should be about the same at half load as at full load may be surprising, but Fig. 5 tends to prove the truth of this assertion and other such diagrams could be given. It will be noticed that the ice production varies from month to month, but the curve representing tons of ice per ton of 10,000 B.t.u. fuel is nearly flat.

Fig. 6 illustrates in a greater detail the foregoing contention. The curves, of course, apply only to a certain plant, and characteristics will vary with each plant. Still in a properly designed plant, and even in improperly designed ones, they will, or should, under proper operating conditions, follow the directions as given on this chart. It will be noticed that the ice-tank temperature increases as the load drops off, up to 20 deg. F., at which point it becomes flat. This curve is the base on which the efficiency of the system is built. The increase of the ice-tank tem-

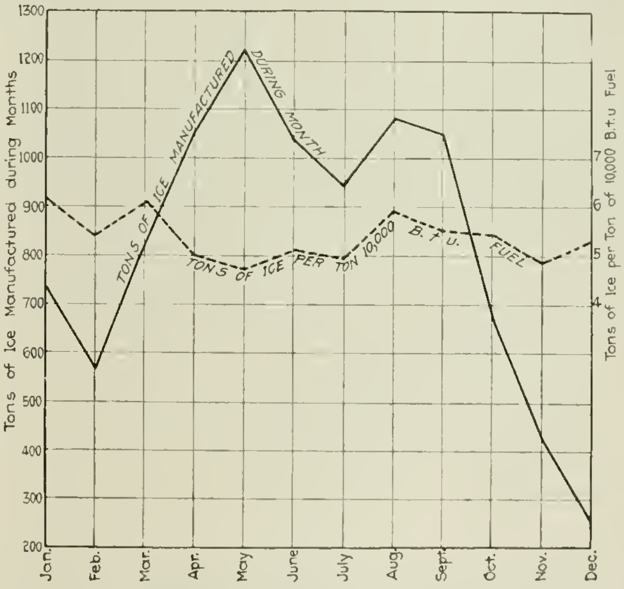

FIG 5. ECONOMICAL PERFORMANCE OF SIMPLE ICE PLANT WITH VARIABLE LOAD FACTOR

perature is the factor that governs the increase of suction pressure on which the economy depends. All too frequently, it will be found that the ice-tank temperature maintained under low loads is the same or even lower than at periods of full ice production. A great many plants in winter will have half of their tank frozen down with ice. It is known that large can surface per ton of ice is a factor of economy, but this can surface must be working, and not idle. The minute a block of ice becomes frozen solid, the can holding it ceases to do work, and if there are twenty cans per ton of ice in the tank and half of them contain solid frozen blocks, then, actually there are only ten cans per ton of ice, with the resulting necessary higher temperature difference to freeze the required amount of ice.

TABLE IV. RELATIVE EXPECTED EFFICIENCY OF VARIOUS ICE-PLANT INSTALLATIONS

	Rel. Eff. Per Cent.	Tons of Ice Per 20,000,000 B.t.u.	Increase of Heat Req. per B.Hp. at ½ Load Over Full Load	Ther. Eff.
Diesel engine	100	30	5.5	33.8
Gas-producer and engine	60	18	36	20.5
Locomobile	40	..	38	13.6
Turbine	36	.	7	12.2
Uniflow condensing engine	32	9.6	4	10.9
Corliss compound cond. engine	27	9.0	22	9.9
Uniflow non-condensing engine	21	6.3	8	7.0
Corliss compound non-condensing	20	6.0	21	6.8
Simple Corliss non-condensing	16	4.9	20	5.4
Simple engine non-condensing	14		17	4.8

Chart is calculated on a standard of 70 per cent. boiler and grate efficiency. An allowance of ½ hp. was made for refrigerating auxiliary load per ton of ice. A total of 3.5 b.hp. was taken per ton of ice, which corresponds to a back pressure of about 15 lb. suction and 185 lb. condenser pressure.

As soon as frozen, ice should be pulled, up to the point where the tank temperature gets to be 20 deg. F. Ordinarily, a higher tank temperature is not advisable owing to the danger that in case of a shutdown or breakdown, the tank temperature is liable to climb to the point where the ice in the can would begin to thaw and upon freezing damage the cans. The amount of frozen blocks in the tank is sufficiently important to warrant careful attention and should be made an item of daily report.

In the further study of Fig. 6 it will be noticed that as the suction pressure goes up the condenser pressure comes down. While the suction pressure is definite and can be calculated, condenser pressure in some plants and climates will go lower even than shown, or perhaps will tend to hold up, but it necessarily will always decrease a great deal with lower loads. With these two factors increasing or decreasing as shown, the compressor horsepower will decrease. This will reduce the amount of steam the prime mover requires per ton of ice, but owing to the fact that the economy of the engine decreases with the speed, the drop of the steam curve will not be as pronounced.

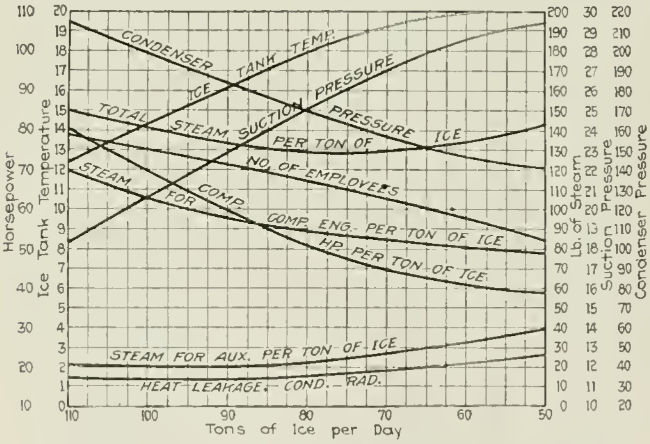

FIG. 6. GOOD ICE-PLANT PERFORMANCE, VARIABLE LOAD FACTOR

The steam required for auxiliaries per ton of ice decreases with the load. Heat leakage, condensation, radiation naturally remain constant. Adding the heat leakage, auxiliary steam and main engine steam gives the composite, or total, steam per ton of ice. This drops off, then increases, and at half load is practically the same as at full load. Consequently the fuel cost per ton of ice should be the same at half as it is at full load.

Table IV shows the relative efficiency of various prime movers for ice plants. The data here and also in other parts of the paper are based upon 20 million B.t.u., equal to a ton of 10,000 B.t.u. fuel. The general acceptance of this standard would make possible accurate comparison of plant operation. The data given in Table IV are conservative and should be attainable with reasonable operating ability. The column showing increased heat or power required at one-half load over full load is especially important in ice plants, where the load is so extremely variable.

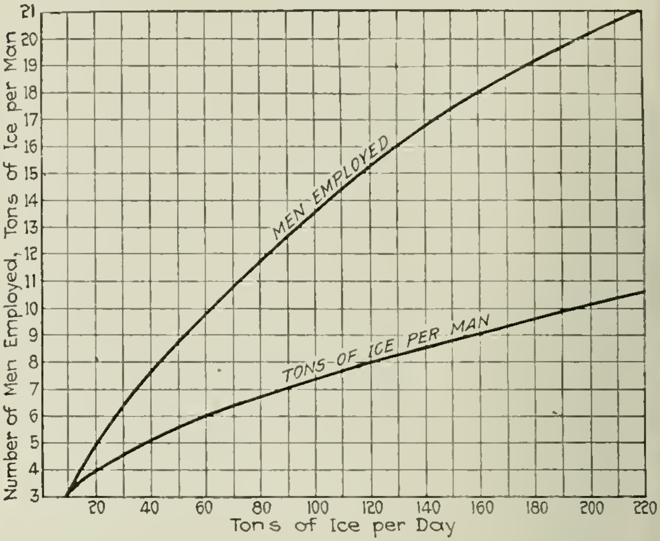

FIG 7. LABOR IN STEAM-DRIVEN ICE PLANT

Next to the fuel cost per ton of ice ranges the labor cost. Fig. 7 gives a good idea of what is to be expected in the average properly operated steam-driven ice plant.

The Plant Engineers' Club of Boston

The Plant Engineers' Club was planned in 1915 by Henry S. Dennison, of the Dennison Manufacturing Co., and E. D. Freeman, of the B. F. Sturtevant Co., along the lines of a similar organization which includes managers of plants and which is called the Factory Managers' Club. Mr. Dennison gave a dinner at the City Club on June 9 of that year, to which he invited about 25 mechanical engineers, master mechanics and chief engineers of various plants in the vicinity of Boston. As a result of this meeting the Plant Engineers' Club was organized. The meetings, which are held each month, usually are followed by an informal dinner, and occasionally a visit is made the same afternoon to one of the plants represented by the members of the organization.

Considerable time was spent during the first year in the study and preparation of a code for continuous boiler-room tests so that the members could adopt a standard by which they could bring up the over-all efficiency of their plants and compare them with what the other members are doing. They have found this code of great value, and it has a tendency to improve the general efficiency of the boiler plant, obtaining very much better results than they had been able to get formerly. The next meeting will be held at the Boston City Club, Mar. 20, at 6:30 p.m., and will be devoted to a discussion of the Cost of Coal Handling and the Storage of Coal. Mr. Eaton, of the Waltham Watch Co., will also recount his recent investigation on the use of powdered coal in large manufacturing plants.

The membership of the club is limited to superintendents, master mechanics and engineers of plants, not more than one in each line of business and not more than 25 in all. The officers are: G. L. Finch, president; H. C. Eaton, vice president; H. S. Scott, secretary-treasurer.

Lubrication of Air-Compressor Cylinders

Recent disastrous explosions in air-compressor systems present striking examples of the danger existing from the use of ordinary engine oil in the air cylinders of air compressors. Only a pure mineral oil, with a flash point as high as good lubricating qualities will permit, should be used. As little as possible of even the best oil should be used.

Numerous cylinder oils are compounded, and such oils are likely to produce a carbon that will stick the valves and collect on valve faces and other parts of the cylinder and valve chambers, resulting in a dangerous condition.

Air receivers are liable to explosion from accumulated oil deposits. Every receiver should be equipped with a pressure gage, a safety valve, and proper drains, and all reservoirs and likely places of deposit in the air line should be thoroughly and frequently drained and cleaned. It is bad practice to have the inlet of an air compressor take from a hot or dusty room—the air should be cool and as clean as possible.

The practice of throwing kerosene oil into the inlet of an air compressor to clean it is an extremely dangerous one, and the cause of an explosion under such circumstances is not difficult to understand. Lubrication of the air cylinder with soapsuds (preferably made of soft soap, about one part soap to fifteen parts water) for a few hours each week (or less frequently if the load is light), instead of oil, will help very materially in keeping the cylinder clean. The only danger from the use of soapsuds is rust, and this should be overcome by being careful to discard the soap and feed the cylinder with oil an hour or so before shutting down. The receiver blowoff should then be opened and the accumulation of oil and water drained off.

An air-compressor engine should not be controlled by the air pressure alone, as many are, but should be fitted with an auxiliary governor which will act as soon as the speed rises above a certain predetermined limit. This will prevent the engine from "racing" in case an accident to the tanks or piping causes a sudden lowering of the pressure. It is not necessary for an explosion to take place to produce a lowering of the pressure, as the giving way of a pipe, valve or tank from any cause will have the same effect.—*The National Safety Council.*

Engine-Room Rules

Employees should be strictly forbidden to enter the engine room except for a special mission, and then should remain only as long as necessary.

The engineer should not be permitted to leave the engine room until some other attendant who is thoroughly familiar with the engine, valves and signals is present to take charge.

No person other than those responsible for the operation of the engines should be allowed to touch any valves or other part of the mechanism or approach any moving part.

No one except the attendants should be permitted to go inside the railings or upon footways when the machinery is in motion.

The safe speed for each flywheel should be known, and in no case should this be exceeded. Flywheel revolutions should be recorded every day in order to make sure that the engine is not running over the speed limit.

All parts of engines and accessories should be frequently and thoroughly inspected, and daily tests should be made of the governor mechanism and automatic engine stops.

Under no circumstances should engines be started until they are thoroughly cleared by alternately blowing live steam through each end of the cylinders, and the steam pipe and cylinders thoroughly drained of all water. The drip should be left open until the load is put on and then closed. Be sure to warm the engine cylinder at both ends.

In shutting down, the drip valve should be left closed until the engine is stopped. If the throttle is equipped with a bypass valve, the throttle should be closed and engine stopped with the bypass. This gradually stops the engine, avoids the pumping effect of the piston and prevents water being drawn into the cylinder.

Never attempt to "bar" a flywheel around nor pull it off center by grasping the belt when the steam pressure is on.

Never start to take cylinder head off or piston out of cylinder without making sure that the throttle and exhaust valves are shut tight and locked and the drains wide open; nor without trying the indicator cocks to see whether there is any pressure on.

Never stop the air pump before stopping the engine (condensing), as the condenser and exhaust pipe may be flooded and overflow into the cylinder.

All steam traps should be kept clean and in working order. Should a trap get out of order, and it be impossible to repair it at once, the bypass should be opened sufficiently to pass off all water which might collect.

Leaks in pipes, flanges or gaskets should be repaired at the earliest possible time.

In opening up a cold line, all available drips should be opened. The line should be warmed by opening the bypass where possible or by opening the stop valve sufficiently to warm very slowly. Never open the main valve until certain that the line is thoroughly heated. An inexperienced attendant should not be allowed to turn steam into a cold line until properly instructed.

Automatic valves should be frequently examined to insure their proper action in emergency.

Under no circumstances should vacuum breakers, governors, engine stops or other safety devices be blocked or otherwise made ineffective. If such apparatus is out of order, it should be repaired at once.

Do not stand in front of cylinder head of engines.

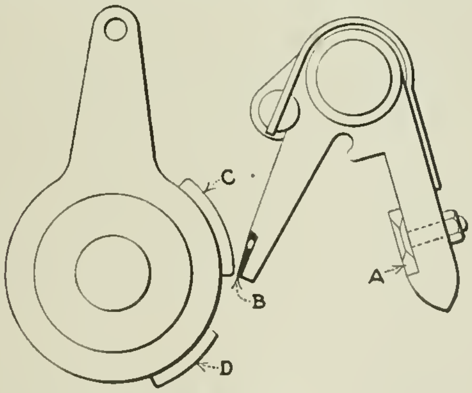
Do not place any material, tools, etc., on platforms or stairs around engine. They might fall off and injure someone below.

Never work in a gas-engine room alone; always have a helper with you.

If you find a man overcome with gas, get him into the open air at once, send for the doctor and notify the foreman.

Smoking and open lights should be forbidden around gas machinery and gas pipes; otherwise an explosion might occur.—*The National Safety Council.*

It occurs not infrequently that the steel toe B becomes worn down as shown in the illustration (reproduced from *Power and the Engineer* for Apr. 20, 1909). In order to get the desired trip after the toe B has worn down thus, attendants have been known to shorten the regulator rod so as to bring down the steel C nearer to B. This practice usually results in throwing the safety-cam or trip D out of reach of the toe B. The danger attaching to such a condition is obvious. If the governor belt should break, away goes the engine with steam being admitted full stroke, unless perchance the engine is equipped with an independent safety stop or a "governor stop." The engineer should also make sure that he does not make the safety trip inoperative by rolling the eccentric ahead, in order to get compression at the end of the stroke.—*The National Safety Council.*



SAFETY CAM TOE EXCESSIVELY WORN

Daylight Saving Advocated by United States Chamber of Commerce

Fifty-two important reasons for the prompt passing of the daylight-saving bill were recently given Congress in the report of the Committee on Daylight Saving of the United States Chamber of Commerce. The items in relation to the immediate reduction in the use of light and heat, with the attendant saving of coal, are of the most interest to engineers and manufacturers.

More than 1,500,000 tons of coal a year is the estimated saving even if the measure is in effect only for the shortest period that has been suggested; and the saving in fuel oils is equally impressive. The savings would occur in both direct and indirect ways. The amount of coal that will be saved if the clock is moved ahead one hour would differ with the method in which daylight saving is used. Calculations computed for different periods based upon the actual British experience in the summer of 1916, and modified by allowances for differences in latitude give the following savings in coal for the United States:

1. Saving of 150 hours of a yearly average of 1320 per year requiring artificial illumination in the United States, that is, by daylight saving between second Sunday in April and last Sunday in September according to the Calder bill (S. 1854) now before the House Committee on Interstate and Foreign Commerce:

	Tons Coal
In electricity for lighting	660,000
In gas for lighting	144,000
	804,000

2. Saving of 190 hours from the yearly average; that is, with clocks moved ahead one hour between Apr. 1 and Nov. 30:

	Tons Coal
In electricity for lighting	836,000
In gas for lighting	183,000
	1,019,000

3. Saving of 198 hours from the yearly average; that is, with clocks advanced one hour throughout year:

	Tons Coal
In electricity for lighting	871,000
In gas for lighting	190,000
	1,061,000

The saving in coal used for these purposes could be represented approximately by the following percentages:

1. With saving of 150 hours: Amount of coal used for lighting through gas and electricity, approximately 15,750,000 tons; amount saved, 804,000 tons; percentage saved, 5.

2. With saving of 190 hours: Amount of coal used for lighting through gas and electricity, approximately 15,750,000 tons; amount saved, 1,019,000 tons; percentage saved, 6.5.

3. With saving of 198 hours: Amount of coal used for lighting through gas and electricity, approximately, 15,750,000 tons; amount saved, 1,061,000 tons; percentage, 6.6.

These figures do not include the saving that would be obtained at isolated plants and at electric-power plants which sell power for lighting. To be borne in mind, too, is the fact that the estimate has been made on a basis which assumes that the use of electric energy and gas for lighting is spread evenly over the country, whereas as a matter of fact 57 million electric lights out of a total of 76 million in the country are in the New England, Middle Atlantic and Northern Central States, where the advantages of daylight saving will be most striking.

The saving of coal through substitution of a morning hour of moderate illumination for an evening hour of maximum use of electricity and gas illustrates ways in which very important savings in coal would be obtained.

"Great Britain, France, Italy, Germany, and eight other nations have adopted daylight saving since the outbreak of the war," says A. Lincoln Filene, of Boston, chairman of the committee that prepared the report for the United States Chamber of Commerce, "and in all of them it is a great success. In England the saving in the use of artificial light and fuel is estimated at $2,500,000 for the summer months alone. In France the saving has been estimated to be 10 per cent. of the coal ordinarily consumed by the gas and electric undertakings. Adopted as a war measure, it has resulted in such increased efficiency and such marked economy that there is no question of a return to the old ways after the war."

Supporting the daylight-saving measure are the President of the United States; Herbert C. Hoover, the United States Food Administrator; Dr. Harry A. Garfield, the United States Fuel Administrator; E. N. Hurley, Chairman of the Shipping Board; the Council of National Defense, literally scores of state and municipal civic bodies and the more than one thousand chambers of commerce and commercial organizations comprising the membership of the Chamber of Commerce of the United States.

New Jersey Boiler Inspection Bureau

A boiler-inspection bureau for the State of New Jersey was provided by the legislature at its recent session by passage of Senate Bill No. 209, which has received the approval of Governor Walter E. Edge. The act goes into effect immediately. The bureau is established in the Department of Labor, consisting of the Commissioner of Labor, as head, and the members of the Steam Engine and Boiler Operators' License Bureau of the Department of Labor that was created under the provisions of the act approved Apr. 14, 1913, and amended by the act approved Mar. 29, 1917, together with such inspectors as the Commissioner of Labor shall deem necessary. The new bureau will be in charge of the inspection of all steam boilers located within the state carrying a pressure of more than 15 lb. per sq.in. Section 3 of the law provides:

> Any person who shall be a citizen of the State of New Jersey, who has had at least five years' experience as an engineer in the care and operation of steam boilers, or who has had at least five years' experience as a boilermaker, or who has been for five years an inspector of an insurance company issuing insurance upon boilers and licensed to do business within this state, who shall satisfactorily pass the examination hereinafter provided for, shall be eligible to the office of inspector in the said Boiler Inspection Bureau.

The Commissioner of Labor is authorized to direct the members of the Steam Engine and Boiler Operators' License Bureau to hold examinations of inspectors, and he is to prescribe the rules and scope of the examinations, appoint the necessary inspectors from among the successful candidates and issue licenses to inspectors so appointed. When so licensed, inspectors are authorized and empowered to conduct inspections and examination. Inspectors shall hold office during the pleasure of the Commissioner of Labor and shall perform such duties as he may direct.

The act requires that all steam boilers within the state carrying a pressure of more than 15 lb. per sq.in. shall be inspected internally and externally and be subjected to a hydrostatic test, "if necessary," at least once in each year by an inspector of the bureau, excepting boilers that are inspected in accordance with the act by insurance companies, whose inspectors have been duly licensed by the Commissioner of Labor. The owner of any steam boiler who shall use or allow to be used a steam boiler in violation of any provision of the act shall be liable to a penalty of $50 to $100, to be collected by suit in the name of the Commissioner of Labor. Section 15 provides that all steam boilers shall conform to the regulations and standards adopted by the State Board of Boiler Rules.

Steam boilers in marine or railroad service that are subject to United States Government inspection and regulations and also fire-department apparatus and motor road vehicles are excepted.

A fee of $6 and traveling expenses of the inspector is to be paid by the owner of each boiler inspected and collected by the inspector, $1 of which is to be turned into the state treasury and $5 and expenses to be retained by the inspector as his compensation.

In addition to the annual internal and external inspection, each boiler is to be inspected externally as nearly as may be at the expiration of six months after the annual inspection. For such external inspection the owner of the boiler is to pay the inspector a fee of $2.50 in addition to the actual railroad fare.

Bituminous Coal To Be Mined Clean or Sold at Less Than Fixed Price

The United States Fuel Administration has announced the organization of an inspection system to enforce the mining of clean coal.

During last winter much of the output of bituminous coal reached the market containing a large percentage of slate and other impurities. The effect of this has been not only to reduce the heating value of the coal, but to put an additional unnecessary burden upon transportation facilities.

Under the inspection system, coal condemned by the Fuel Administration for lacking preparation or because it contains a high percentage of impurities will be sold at 50c. per ton less than the fixed Government price for the mine.

ORDER EFFECTIVE MONDAY, MAR. 11

The inspection system will be operated through the district representatives of the Fuel Administration in the various coal fields. The order became effective Monday, Mar. 11. It provides:

UNITED STATES FUEL ADMINISTRATION,
Washington, D. C., Mar. 7, 1918.

REGULATION CONCERNING CLEAN COAL

The United States Fuel Administrator, acting under authority of the Executive order of the President of the United States dated Aug. 23, 1917, appointing said administrator, and in furtherance of the purpose of said order and of the purposes of the act of Congress therein referred to and approved Aug. 10, 1917, hereby orders and directs that until further or other order, and subject to modification hereafter from time to time and at any time:

Section 1: Authority is hereby given to the district representatives of the United States Fuel Administration to appoint a sufficient number of inspectors in their respective districts to carry out the terms and provisions of this order, and to assign to each of said inspectors a particular territory.

Section II: It shall be the duty of each of said inspectors:

1. To cover his territory at as frequent intervals as may be consistent with thorough inspection; the inspectors shall be qualified by knowledge and experience of the particular district or districts in which the inspection is to be performed, and shall familiarize themselves with the conditions under which the coal is produced and prepared, so as to enable them to effectually carry out the terms and provisions of this regulation, the intent being to reinstate the cleaning of coal at the working faces of the mines; to reinstate employment of slate pickers with a view of bringing the ash contents of coal back to approximately the standard of normal times. Furthermore, where the coal in any part of the mine is found to be naturally of such character as to be unfit for market, judging from the usual standard of the district, the district representative may order the mining suspended in said part or parts of a mine until or unless proper cleaning methods be adopted; provided, however, that the workings shall not be so suspended where the nature of the mining to be done is necessary to preserve the mine from damage, or where a cessation of work endangers life or may result in serious risk of flooding, of explosions, or of squeezing.

2. To report daily to the district representative of the Fuel Administration, mines inspected, the condition of the coal as loaded; methods being employed to prepare and clean the product; whether or not the product being shipped to market is, in his judgment, a well-prepared and merchantable product. All reports of inspections shall be made in quadruplicate, one to be forwarded by mail to the Fuel Administration, Department of Inspection, at Washington, D. C.; one to the district representative; one to the operator; and one to be retained by the inspector for his personal files.

Section III: Inspectors are authorized to condemn at the mines any coal loaded in railroad cars which, in their judgment, is not properly prepared; and any inspector finding unmerchantable coal shall immediately notify the district representative and the operator by wire or in person and in writing, giving the car numbers and initials of any and all cars so rejected and stating the facts on which such action was based. A copy of such notice shall be immediately mailed to the United States Fuel Administration, department of inspection, and to the district representative. If the district representative approves the inspection report, he shall so notify the operator at once; in which case, unless the operator unloads and reprepares the rejected coal, the consignee shall be permitted to deduct 50c. per ton from the authorized price for the grade of coal with which the car is loaded, provided, however, the consignee after examining the coal may at his option pay and the operator may receive the full authorized price. Each invoice covering the sale of condemned coal shall bear the following notation, "This reduced price is fixed by the United States Fuel Administration as a penalty for improper preparation." The operator shall thereupon immediately report to the United States Fuel Administration, department of inspection, at Washington, and to the district representative the disposition made by him of said car or cars of coal, and shall accompany his reports with a copy of the invoice.

The district representative, where repeated violation of this regulation has taken place, or in flagrant cases, shall require a special written report from the operator, which report shall be transmitted by said district representative to Washington with his conclusions thereon, all of which is subject to review by the United States Fuel Administrator.

This order or regulation shall not operate to change the terms, conditions, or validity of existing contracts, but new contracts shall be made subject to this order.

Above regulation to become effective Mar. 11, 1918.

H. A. GARFIELD,
United States Fuel Administrator.

Coke Breeze for Steam Raising

In a recent paper on low-grade fuels for power, before the Liverpool Engineering Society, Mr. Kershaw, as reported in the *Power User*, pointed out that coke breeze, as the fine coke is called which is washed from the quenching tables and grading screens in gas-works and byproduct coking plants, has lately come into prominence as a useful and cheap fuel for power generation. The ash content varies from 20 to 30 per cent. and the moisture from 10 to 20 per cent., so that it may be classed as low-grade, either on account of its contents of incombustible matter, or on account of its fine state of subdivision.

The conditions required for the successful combustion of coke breeze under steam boilers are now well understood, and there are many plants in operation in this country where it is being employed either alone or mixed with ordinary bituminous fuels for steam generation. When coke breeze or coke ash containing over 30 per cent. of incombustible matter is to be burned alone, some form of external furnace of the dutch-oven type becomes necessary for its complete combustion, and in this case the advantages offered by the internal fireboxes of the marine and Lancashire type of boiler are lost. Forced draft will still be necessary to burn the fuel, and the radiant heat from the furnace can be utilized by means of hollow walls for preheating the air before it is drawn into the furnace by the fan or steam jet—the heat of the gases can be best utilized in the water-tube type of boiler. Underfeed stokers are sometimes used with this furnace, but as the proportion of ash in the fuel rises, the difficulty of obtaining anything like complete combustion of the carbonaceous matter with mechanical stokers increases.

When burning a mixture of bituminous coal and breeze, it is very important that the fuel should be well mixed. A method of burning the mixed fuels on chain-grate stokers which is stated to have given good results is to fit an additional hopper to the front of the stoker, by means of which a layer of breeze is fed on to the chain-grate before the ordinary fuel comes down upon it from the hopper above. The grate then travels forward with two layers of fuel upon it, the coke below and the bituminous above, and the proportionate depth of these two layers can be varied by altering the relative speeds at which the two hoppers deliver their fuel onto the grate.

The idea that a technical paper is dry at best, and that the English employed in it is of small consequence has long been proved incorrect. There is so much nowadays that is well written that no busy professional man will spare the time to read and digest an ill-written paper.—*Harrington in the Sibley Journal.*

Merchant Marine Conference at Boston

Problems that are expected to result in greater efficiency in the manning and operation of American merchant ships, improvements that will be welcomed by the ship operators and crews alike, were discussed in a conference of representatives of leading maritime organizations and United States Shipping Board Recruiting Service officials at Boston, Tuesday, Mar. 5.

Henry Howard, director of the Shipping Board Recruiting Service, presided. Among those taking part were Edward F. Flynn, assistant to the director of recruiting; John H. Pruett, of New York, national president, American Association of Masters, Mates and Pilots; Andrew Furuseth, president, International Seamen's Union; H. P. Griffin, president, Marine Cooks' and Stewards' Association of the Atlantic and Gulf; Thomas L. Delahunty, of New York, business manager, Marine Engineers' Beneficial Association; John Olson, of the Marine Firemen, Oilers' and Watertenders' Union of the Atlantic and Gulf; Bert L. Todd, of New York, secretary, Ocean Association of Marine Engineers; Parker H. Kemble, and Henry G. Vaughan and Edwin Reynolds of the Shipping Board Recruiting Service.

In the afternoon the delegation went on board the training ship "Governor Dingley" for luncheon and an inspection of seamanship and boat drill by the merchant marine apprentices being trained by the Shipping Board.

Effect of Poor Coal on Plant Efficiency

An interesting analysis of the effect of poor coal on power-plant efficiency was presented at a meeting of the New England Street Railway Club in Boston, Mass., Feb. 28, by Walter C. Slade, superintendent power and lines, Rhode Island Company, Providence. Rhode Island has keenly felt the shortage of bituminous coal. The two power-producing utilities at Providence have been operating of late with inadequate coal reserves and the Rhode Island Company in particular has recently been forced to operate its main power plant at Manchester St. for three or four days entirely with borrowed coal. The company operates two steam plants, one a turbine station at Providence with two 15,000-kw. units and some smaller machines, and one at Rockland, of the engine type. In 1916 these plants burned 73,100 gross tons; in 1917 the consumption rose to 90,500 tons, although the power generated increased less than 5 per cent.

The load on these stations is exclusively railway. The diversity factor which the average central station enjoys does not exist on the Rhode Island system. The turbine station generated 73,492,300 kw.-hr. in 1917 and the Rockland station 1,423,217 kw.-hr. In 1915-16 the company paid $3.32 per ton for coal alongside; discharging cost 8.5c. per ton. The average price is now over $8.35, provided there are no demurrage charges. Owing to Government regulation, the consumer absorbs not only demurrage charges, whether they occur on cars or on the boat at the loading end or at the discharging end, but also other charges such as war taxes, insurance, etc. To date the company has received about $6000 in demurrage bills on the last eleven boats, on which two-thirds was incurred at the loading end. Discharging costs have advanced to 23c. per ton, because the company is now obliged to discharge boats on overtime work to avoid the high demurrage charges. Today coal passers on the water front are getting 50c. per hour straight time, 65c. per hour overtime and 75c. per hour Sundays and holidays.

In August, 1917, the company realized that it was going to have trouble with fires in part of its stored coal, due to the rapid heating properties of some of the coal, which was of poor quality even though of high price. The fire trouble actually occurred earlier than was anticipated. About Sept. 1 shipments became less frequent, and in December the reserve-storage supply was reduced to about 7500 tons. In February the coal left was all consumed and the company was forced to borrow coal through the local fuel administration. For the last year all possible pressure was exerted to have suitable deliveries kept up to prevent the depletion of the supply.

Prior to the time when the coal-mining conditions became abnormal and transportation facilities became demoralized, the company burned New River or Pocahontas coal, with an average analysis of about 14,900 B.t.u. Even the same grade of coal, due evidently to poorer preparation at the mines and at a later time possibly to pooling of coal supplies by the Government, gave noticeably lower average B.t.u. on analysis. The spot cargoes purchased outside, consisting mainly of Pennsylvania coals, but which were expected to be of average quality, were in some instances of extremely poor quality. Of the coal placed in yard storage, 35 per cent. showed a heat value under 14,500 B.t.u., and 46 per cent. under 14,750 B.t.u. In fact, 21 per cent. was under 14,000 B.t.u., some of it containing 15 per cent. ash. Owing to the deterioration of this coal in storage before it was consumed under the boilers, the average B.t.u. value of the coal as fired was not over 14,300 B.t.u. The poor quality of coal was reflected in operating cost, in addition to the higher cost of the coal alongside. Increased boiler-room maintenance also resulted. The net result was to raise the unit cost of power for 1917 by 106 per cent., compared with the year ended June 30, 1916.

The coal factors for both stations have been growing worse since 1916, as shown:

	—Manchester St. Station—		—Rockland Station—	
	Lb. Coal Per Kw.-Hr.	Per Cent. Increase	Lb. Coal Per Kw.-Hr.	Per Cent. Increase
12 months ending June 30, 1916	2.28	....	3.49	....
6 months ending Dec. 31, 1916	2.38	4.4	3.78	8.3
12 months ending Dec. 31, 1917	2.69	18.0	3.99	14.3

The unusually high factor for the turbine plant in 1917 was due to a combination of operating conditions requiring a large number of banked hours on stand-by boilers not used in 1916, together with the necessity of burning a considerable amount of inferior coal, as well as coal damaged by spontaneous combustion. The performance will not be repeated in 1918. In fact, under favorable conditions the plant in Providence was operating for a part of January at 2.13 lb. The decrease in economy at both turbine and engine plants has been of the same relative order.

As regards the increased cost of busbar power, some comparisons may be made with the costs which apply to the year ended June 30, 1916. Comparing the last six months of 1916 and the year 1917 with this period, it is found that the cost per kilowatt-hour at the bus increased for the six months 23.4 per cent. and for the following twelve months, 106 per cent. at the Manchester Street Station. At the small Rockland plant the busbar cost increased for the same periods 31.8 per cent. and 73.5 per cent. These remarkable increases in unit cost are due primarily to the abnormally high price and also to the poor character of the fuel. Some of the coal was of such poor quality that it raised the maintenance of stokers and furnaces to an abnormal point. Steam-plant maintenance in 1917 increased 75 per cent. compared with 1916, and all other maintenance increased only 13 per cent. at the Manchester Street Station. The increase in the cost of fuel as fired was 132 per cent. and raised the fuel charge in 1917 to as much as 83 per cent. of the total maintenance and operating costs. Referring to operating charges in the same year, while fuel costs advanced 132 per cent. over 1916, wages advanced 30 per cent. and all other operating charges 25 per cent. The kilowatt-hours delivered increased only 4.9 per cent. and the pounds of coal per kilowatt-hour 18 per cent.

The majority of the existing railway plants were built at a time when 25 cycles was the only commercial frequency considered suitable for traction purposes. These plants as a rule enjoyed no diversity factor in their load. So much capital is invested in these large railway plants that even though they are able to generate less economically than adjacent central stations, it is difficult to consider anything but a continuance of operation with added improvements in the interest of economy in these railway installations. Between the average large 60-cycle central station and the average large 25-cycle railway plant there can be no interchange of power except through frequency-changing equipment, which is sufficiently uneconomical to make such an exchange feasible only for emergency service. In certain cases it appears feasible to add some 60-cycle equipment in extending existing 25-cycle plants, where intimate coöperation exists between the two classes of plant owners. The writer believes that many of the smaller railway plants of the engine-driven type should be shut down by central-station service, holding that with increasing cost of coal the balance is all in favor of the central station. It is questionable if the price of coal in future years reaches a minimum that is $1 to $1.50 a ton above prices prevailing before the war.

In ordinary times the fuel item represents from 70 to 75 per cent. of the total cost of generated power. Recently, this reached 83 per cent. on the Rhode Island system. In fact, at least 90 per cent. of the total cost was expended in the boiler room for fuel, water, wages, supplies and materials required for maintenance. The boiler plant has been too much neglected in the past, especially in employing high-priced men to operate it. Now there is a man shortage, and perhaps the best solution is to put under the chief engineer a technically trained man or at least a man who understands the theory of combustion well and who can keep a constant check on the operation of the boiler room. This type of man has been termed "combustion engineer." Even plants of moderate capacity could well afford to maintain such a man on the payroll. Working with the assistance of the necessary measuring devices, such a man could put the true spirit of industrial control into boiler-room practice. To aid the combustion engineer in effecting the desired economies, it is advisable to consider the question of making all equipment as nearly automatic as possible. Man power may be at a premium for some time to come, and at all times undue dependence upon the human element is undesirable.

Toluol from City Gas

In anticipation of the present national emergency, says *Iron Age*, there has been going on without any publicity a development in toluol manufacture which bids fair to be of the utmost importance to the nation in the supply of trinitrotoluol. Early in 1915, the Koppers Co., of Pittsburgh, which at that time was building a large number of byproduct coke plants, and in connection with which it was also building benzol and toluol plants, started in the laboratories of the Mellon Institute, Pittsburgh, an investigation into the recovery of toluol from carburetted water gas, the gas made in all large cities of the country by the gas companies for domestic use.

It has been found that every byproduct coke-oven plant in the country is producing or has arranged to produce toluol to the utmost capacity and that the remaining needed toluol must be secured from city gas. The Pittsburgh By-Product Coke Co., an operating company associated with the Koppers Co., has carried out a plan in conjunction with the gas-light company at Washington to erect the first plant at the West station of that company to effect the removal of toluol from 5,000,000 cu.ft. of carburetted water gas per day. This plant was placed in operation on July 14, 1916, and has yielded since that date 200,000 gallons of toluol. While this plant was the first to use this process, and many improvements increasing the efficiency and economy of operation have been introduced, it proved a commercial and technical success, equaling the results promised by laboratory methods. Many of these "stripping" plants are in operation in various cities, and others are in preparation.

The Belgian Coal and Coke Industry

During the years that immediately preceded the war, Belgium produced, in round figures, 24,000,000 metric tons of coal a year. About 1,350,000 tons of this was coked, yielding a trifle more than 1,000,000 tons of commercial coke, including breeze sold for domestic use. All coke was, of course, byproduct coke, as none other has been made in Belgium since 1892 or 1893.

Belgium was a pioneer in the byproduct industry. The oldest byproduct company now in existence is the Société Anonymé du Charbonnage des Produits, at Flénu, Belgium, which was incorporated in 1856 for the mining of coal and the manufacture of byproducts. That company may have become better known abroad as a coal company than as a byproduct concern, but this was due to the extraordinarily fine natural condition of its coal deposits, which enabled the company to pay big dividends earned in mining and selling coal while meeting the stress of developing the byproduct department of its business. Regardless, however, of the trying period of development, the Produits Co. never ceased for a single day, since 1856, to make byproducts; and the first aniline colors ever put on the market were made at Flénu by this company at a time when its coke and byproduct department was managed by the noted Belgian chemist, Neyrincks.

With the advent of the Coppée vertical-flue coke oven, the Produits Co. became a decided factor in the byproduct industry. That was about 1870, at a time when Germany had only beehive coke ovens and when all coke made in Belgium was produced in retort ovens of the original Coppée design. Not only was Germany later than Belgium in eliminating its beehive ovens, but even to this day there is not in Germany a single coke oven which is not of the vertical-flue kind first invented by Coppée, a Belgian, or the horizontal-flue type developed by Solvay and Semet, the former a Belgian, the latter a Frenchman, both living today. Many persons in this country, even among those engaged in the byproduct industry, believe that the byproduct oven is of German origin and development. To this day the Belgium coke ovens have always kept at least one step ahead of all others.—*Coal Age.*

Science or Art

There are times when we find it difficult to take any interest whatever in education, times when the mere word bores us, calling up dull recollections of tedious debates and the incessant repetition of those platitudes, formulas, pious hopes and bitter criticisms, which for many a long year have been the currency of educational conferences. To men thus weary of the subject, we recommend a little book by H. G. Taylor, lecturer in civil and mechanical engineering at King's College, the University of London. According to their point of view, it will make them angry or rejoice them. If they are university men, if they are mathematicians rather than engineers, they will be roused either to wrath or contempt; if, on the other hand, they are inventors or manufacturers, and, above all, if they are men who owe more to practical training than to college classes, they will applaud the author's argument.

Mr. Taylor is a whole-hearted advocate of a thorough practical training. A Whitworth scholar himself, he believes in the Whitworth method. Engineering, he says quite bluntly, is not a science, it is an art, and it is not to be learned by abstractions, but in the workshop, the factory and the field. A man, he holds, must first be an engineer by nature; he may then be taught to think scientifically, but "to be useful to him, any elementary science must become an idea over which he has complete control." With the exception of the method of training naval cadets, for which he has nothing but the highest praise, Mr. Taylor does not think any one of our universities gives this desirable control. "Without exaggeration," he writes, "for an engineer who has to make his way in life, the worst thing he could possibly do is to become educated." The training that is given in the schools lacks reality, and depends too much upon mathematical abstractions. "To a man with good mathematical knowledge and no engineering experience, all problems resolve themselves into mathematics, and his engineering credulity obtains for him the desired success."

We are disposed to agree with him. The mathematics employed in the ordinary course of mechanical and civil engineering are small indeed, and the advanced teaching is unnecessary, and in many cases even vicious, since it gives a wholly false idea of the truth and encourages a belief in mathematical dogma. Meticulous accuracy in engineering calculations is impossible, because there are always many unknown quantities and qualities. Hence broad calculations which allow a margin for error are always used in practice. For general purposes the engineer will learn more about heat from the experiments and simple arithmetic of Tyndall than from the textbooks of Rankine. The instinct that is acquired by doing things is more useful in this work-a-day world than mathematical abstractions. "The best education for an engineer," says Mr. Taylor, "is found in the natural and instinctive pursuit of manual toil accompanied by study at a technical school." We agree with him. The great engineers of the past learnt by hard experience, and the great engineers of the future will learn by the same methods. The university will never replace the workshop.

There are one or two more words that must be said on this eternal question of mathematics. We went some time ago to visit the dean of a technical college, well known to us in our youth. In our days it was a hotbed of mathematics, and the student who did not revel in the higher flights of "conic sections" had a poor chance, indeed, of achieving distinction. We found a great change. The present dean was bred in the workshop, and he holds that the drawing office rather than the classroom is the proper place to teach the science of figures. With a sly twinkle in his eye, he admitted that on more than one occasion he had found his students busy over their boards, engaged in the actual design of a machine or a structure when they ought to have been attending a lecture on abstract mathematics. His duty obliged him to pack them off straight away, but we could see that his sympathy, as a man and an engineer, went out to them. He knew that these youths had in them the making of real engineers. They were fired by that love of creating, that desire to make things, which is the call of our profession. Where arithmetic or algebra, geometry or the calculus was needed for the construction of something, they used it gladly, as they would any other instrument or tool, but they could not look upon mathematics as an end in themselves. We dare say that this professor is teaching many a man how to handle figures who would never have learned the art from the professors of the subject.

Mr. Taylor is right, we think, when he suggests that mathematics have gained too high an estimation in technical schools. We cannot conceive of an engineer who was unacquainted with the strength of material, the nature of stresses, the means for working metal, stones and timber and the general facts of physics and chemistry. These things and many others must be *known* and handled by the *mind.* But we can quite well conceive a super-perfect Babbage calculating machine that would answer by the turn of handle any mathematical proposition that might be put before it. There are certain things mathematics cannot replace, and it is those things far more than mathematics that should be given the place of honor.

No one, we trust, will run away with the idea that we fail to recognize the value of mathematics; nothing could be further from the fact. Accurate measurement is the basis of science. What we desire to convey is our conviction that good engineers, men of resourcefulness, inventiveness and imagination can be made with far less mathematical knowledge than is now insisted upon. The science of mathematics is best reserved for those who have the aptitude for it. Such men become useful calculating boxes in the hands of others whose natural bent is toward invention and creation. Where you may find a thousand engineers doing useful work in the world with no more than a decent acquaintance with arithmetic, you shall barely find one high mathematician who is also a progressive engineer. —*Random Reflections from The Engineer, London.*

Complaints of Excessive Prices for Soft Coal

Investigation is being made of complaints received by the United States Fuel Administration that operators in some of the bituminous coal fields are charging an excessive price for coal under contracts made before Aug. 21, 1917, embodying prices below those fixed by the President, which contained no sliding scale of labor charges.

Operators against whom charges have been lodged are alleged to be exacting from customers 45c. per ton in addition to the figure set forth in such contracts, and are attempting to defend their course on the ground that they were required to make the increase under the President's order of Oct. 27, 1917, allowing a 45c. per ton increase to cover wage advances for the miners.

Consumers will be protected against such practices of overcharging when their purchases were made under contracts which contained no provision for variations in price to correspond with changes in wage scales. The Fuel Administration previously announced that the President's order in no degree lessened the obligation of operators to make deliveries at prices stipulated in contracts made before Aug. 21, 1917.

Proper steps have been taken to prevent overcharging in such cases. In one case brought to light, one of the large coal companies of the country has agreed to withdraw the 45c. per ton increase which they had imposed in excess of their contract price.

Civilian Workers Wanted for Ordnance Department

Men having a high-school education, some shop training and the natural ability to adapt themselves to new work, may qualify for a Government appointment in which under Government instructors they will receive the necessary training for the following positions: Inspectors and assistant inspectors, field artillery ammunition steel; inspectors, artillery ammunition, cartridge cases, assembling, loading, forging, primers, detonators, shell and shrapnel machining; ballistic inspectors; metallurgical chemists and assistants; inspectors, powder and explosives; inspectors, cannon, forging operations; inspectors, gun carriages and parts; inspectors, gun-fire control instruments; assistant inspectors, motor vehicles and artillery wheels; engineers and assistant engineers, for tests of ordnance materials; inspectors, ammunition packing boxes; machinists, accustomed to work to one thousandth of an inch.

Those who have the required technical training will be placed and advanced as quickly as their ability justifies.

Send in your own application and urge your associates who may be qualified to do so. These positions are under civil-service regulations, but applicants will not be required to report for examination at any place. Applicant will be rated in accordance with education and general experience. No applications will be accepted from persons already in the Government service unless accompanied by the written assent of the head of the concern by which the applicant is employed. Papers will be rated promptly and certification made with least possible delay. Apply or write for further information to C. V. Meserole, Special Representative of the Ordnance Department, U. S. A., Room 800, 79 Wall St., New York City.

Our Greatest Enemy

Comparatively few persons realize how great a toll industrial accidents take of our people every year, states Secretary Redfield. If we are ever so unfortunate as to hear of the loss in a great battle of, say, 10,000 of our soldiers (10,000 killed) the nation would be moved deeply; yet every year twice, perhaps three times, that number are slain in industries of all kinds and almost without its invoking comment. If we were to hear that 1,000,000 of our men suffered wounds in this war, the nation would be troubled; yet industry takes its toll in the form of injuries to persons to an extent nearly three times that number every year. Of this we think but little. There is a real danger, therefore, that in our sympathetic and proper thought for the soldier in the field, we may lose sight of the soldier in the factory, who has his casualty risks as well as his brother in arms. Just as there is a call to service for the soldier and the financier and the nurse and the doctor and the engineer and the mechanic, there is a call to service to see that the precious lives in the country are not wasted and that the bodies of the precious people who make up this country are not crippled.—*Scientific American.*

New Publications

POWDERED COAL AS A FUEL—By C. F. Herington. Published by D. Van Nostrand Co., New York, 1918. Size, 6 x 9 in., 211 pages; illustrated. Price, $3.

The information which the author has collected in this book was largely acquired while he was employed as assistant engineer in the service of the New York Central Railroad Co. Having described the coals suitable for powdering, the preparation and feeding of powdered coal, the author proceeds to discuss the use of fuel in this form in the cement industries, in reverberatory and metallurgical furnaces, under steam boilers and in locomotives. A chapter is devoted to explosions of powdered fuel and a comprehensive bibliography given of the literature of the subject.

COMBINED TABLE OF SIZES IN THE PRINCIPAL WIRE GAGES

A new publication (Circular 67) entitled "Combined Table of Sizes in the Principal Wire Gages," has recently been issued by the Bureau of Standards, Washington, D. C. This table combines in one series the sizes in the American (B. & S.), Steel, Birmingham (Stubs'), British Standard, and Metric Wire Gages, arranged in order of diameters of wires. It gives the diameters of all the gage numbers in these five systems, in mils, inches and millimeters, also the cross-sections in square mils circular mils, square inches and square millimeters. The table is especially useful to those who wish to determine the nearest equivalent in American or British gage sizes of wires, specified in millimeters or square millimeters, or vice versa. This paper is now ready for distribution and those interested may obtain a copy by addressing a request to the Bureau.

MACHINE SHOP PRACTICE — By William B. Hartman. Published by D. Appleton & Co., New York, 1917. Cloth; 4¼ x 6½ in.; 235 pages; 132 illustrations; 10 tables. Price, $1.10.

The man who has no knowledge of machinist tools and machine-shop practice will find this volume of value in that it presents the elementary principles of machine-shop work in a simple and logical manner. Measuring tools are first illustrated and explained as to form and use. This subject is followed by a description of hand and machine-cutting tools, and finally the several machines alone and in combination with the tools are treated. Correct methods in the handling of tools and in the operation of machines are emphasized. All higher mathematics are excluded, and all calculations are confined to the use of simple arithmetic. The data tables in the appendix are such as are found in the general run of handbooks, but they will be useful to the student. The contents cover the following subjects: Chipping; filing and scraping; drills and drilling machines; lathes; straight turning; taper turning; thread cutting; lathe work; planer and shaper; boring mills; milling-machine work; and a chapter dealing with the automobile. Each chapter is concluded by a list of questions. The illustrations are confined to mechanical drawings which will assist the reader in learning to read them and as to their use.

THEORY AND OPERATION OF DIRECT-CURRENT MACHINERY. By Cyril M. Jansky. Published by McGraw-Hill Book Co., New York, 1917. Cloth; 6 x 9 in; 285 pages; 214 illustrations. Price $2.50.

This book has been prepared as a text to meet the needs of students of limited mathematical training. Elementary mathematics has been made use of quite extensively throughout the work, nevertheless the subject has been presented so that an understanding of the principles involved may be obtained even though the reader may be unable to follow the mathematical reasoning.

The book is divided into sixteen chapters embracing fundamental magnetic principles, electromagnetism, electromagnetic induction, units of measurement, transformation of energy, the continuous-current generator and motor, the magnetic circuit of the direct-current dynamo, armatures, uses of electrical energy, types of dynamos, commutation, operating characteristics of generators, operation and care of generators, operating characteristics of motors, operation of three-wire systems, selection and installation of dynamos.

Although this book was written primarily for use in the classroom, it contains much that the practical man can make good use of, especially the last eight chapters, which deal largely with the construction and operation of direct-current machinery. In the first four chapters the author has given considerable space to a discussion on the theoretical magnetic and electrical units, making it clear just what these units are and how they are arrived at.

Obituary

Findlay Clem was killed on Feb. 25 while inspecting a boiler at Owens Station, near Marion, Ohio. He was employed by the J. T. Adams Construction Co.

Personals

M. H. Collins has been appointed sales manager of the new Louisville (Ky.) branch of the Rensselaer Valve Co.

G. W. Bichlmeir, formerly connected with the supply departments of the Missouri Pacific and Kansas City Southern Railway Companies, and also secretary-treasurer of the W. L. Sullivan Machinery Co., is now connected with the machinery department of the Walter A. Zelnicker Supply Co., St. Louis, Mo.

H. A. Brassert, who has been connected with the United States Steel Corporation since its organization, has resigned as assistant general superintendent of the Illinois Steel Co. at South Chicago, in order to devote himself to his personal interests. He will act as vice president of the Miami Metals Co. and subsidiaries, consulting engineer for Freyn & Co, and in a consulting and advisory capacity with the firm of Brassert. Hardy & Tripp. His offices are in the Peoples Gas Building, Chicago.

Loyall A. Osborne, of New York, vice president of the Westinghouse Electric and Manufacturing Co. and chairman of the Executive Committee of the National Industrial Conference Board, has been appointed by the Secretary of Labor a member of a committee on industrial peace during the war. This committee, which consists of five representatives of employers, five labor leaders and two public men, will provide a definite labor program in order that there may be industrial peace during the war, thus preventing interruption of industrial production vital to the war.

Engineering Affairs

The Sinton Hotel, Cincinnati, Ohio, has been selected as the headquarters for the N. A. S. E. Convention, Sept. 16-21, 1918.

The New York State Educational Committee of the N. A. S. E. and Combined Associations of Greater New York will hold a meeting on the evening of Mar. 26, at 220 E. 15th St., New York City. Walter N. Polakov will give a lecture on "Power-Plant Management," and W. R. Marshall will give a talk on "The Operation of Steam Turbines and Their Auxiliaries." Through the courtesy of Mr. Shillcocks a visit will be made to the power plant of the Loose-Wiles Biscuit Co., Thompson Ave., Astoria, L. I. on the evening of Mar. 22.

Miscellaneous News

A Boiler Exploded at Sharp's farm, Plum township, Penn., on Mar. 8, killing one man and injuring three others. The men were drilling an oil well when the boiler exploded.

A Freight Engine Blew Up on the Wabash R. R. near Cerro Gordo, Ill., on Mar. 3, injuring four persons, wrecking 19 loaded cars, and breaking windows two miles away. The engineer was blown about 20 ft. away.

A Locomotive Boiler Exploded on the Santa Fe R. R two miles west of Williard, N. Mex., on Mar. 3, instantly killing the engineer and fireman and slightly injuring another man who was riding a horse near the scene of the explosion.

Business Was Temporarily Disrupted in St. Louis, Mo, at noon on Mar. 1, when power furnished the Union Electric Co. from the Keokuk Dam failed. The trouble was caused by the grounding of a high tension transmission line.

An Explosion in the Engine Room of the Farley & Loetscher Manufacturing Co.'s plant, at Dubuque, Iowa, on Feb. 21 seriously injured three persons and two men were still missing when the report of the accident was received. The explosion followed a fire that spread into one of the big sawdust conveyors.

The Magnesia Association of America is issuing a portfolio of all the educational publicity given its product during 1917 in the various technical and trade papers, under the title, "Let 85% Magnesia Defend Your Steam." Anybody interested may secure a copy by writing to the secretary of the Association at 702 Bulletin Building, Philadelphia, Penn.

The Bureau of Standards at Washington has purchased eight acres of land west of Connecticut Ave. and has let contracts for a new engineering laboratory, 175x350 ft. and four stories in height. The new building and its equipment will cost in the neighborhood of $1,000,000, and will increase the capacity of the Bureau by 50 per cent. The Pittsburgh laboratory of the Bureau, including the work on glass and ceramics, will be transferred to Washington. It is expected that the new building will be occupied during the coming summer.

Business Items

The Wheeler Condenser and Engineering Co. announces the removal of its Philadelphia office to the Land Title Building, with L. McKendrick as district manager.

The Ketzer Machinery Co. has consolidated with W. H. Robinson & Co., with offices in the Real Estate Trust Building, Philadelphia. Paul R. Ketzer is manager in charge.

The Permutit Co., manufacturers of water-softening and water-rectification apparatus, for several years located at 30 East 42nd St., New York, announces its removal to 440 Fourth Ave.

The Worthington Pump and Machinery Corp. announces the following appointments in its organization: William Goodman, assistant to vice president; William Schwanhausser, chief engineer; Edward T. Fishwick, general sales manager; Charles E. Wilson, assistant general sales manager; James E. Sague, vice president, in charge of engineering and manufacturing; Leon P. Feustman, vice president, in charge of general commercial affairs; Frank H. Jones, vice president, in charge of sales; all at New York City offices, 115 Broadway. Neil C. Lamont, works manager, Laidlaw Works, at Elmwood Place, Cincinnati, Ohio.

Trade Catalogs

Ammonia Fittings and Accessories. De La Vergne Machine Co., Foot of E. 138th St., New York. Catalog. Pp. 92; 6 x 9 in.; illustrated. This company has also issued a bulletin giving ammonia-compressor capacity and list of installations.

Safety Enclosed Fuses, Electrical Protective Equipment and Materials. Electric Fuseguard Co., Newark, N. J. Catalog No. 1. Pp. 54; 6 x 9 in.; illustrated. Describes this company's line of safety electrical-protective equipment and allied materials; list prices are also given.

Electrical Equipment in the Woodworking Industry is the title of a new circular just issued by the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn. The publication is illustrated by views of motor-driven wood-working machinery. In the first section the general subject of motor drive is discussed. The next section is devoted to features of Westinghouse motors which make them suitable for this work. The rest of the book gives horsepower requirements and other data for many different sorts of woodworking machinery which will be of much value to those having to do with this class of industrial activity.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Mar. 14, 1918	One Year Ago	Mar. 14, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Mar. 14, 1918	One Year Ago	Mar. 14 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows

ANTHRACITE

	Circular[1]		Individual[1]	
	Mar. 14, 1918	One Year Ago	Mar. 14, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$7.25—7.50
Buckwheat ..	4.30—5.00	2.75	5.50—5.80	7.00—7.25
Barley	3.25—3.50	1.95	4.00—4.25	4.00—4.25
Rice	3.75—3.95	2.20	4.50—4.80	5.00—5.50
Boiler	3.50—3.75	2.20	....	3.50—4.00

Quotations at the upper ports are about 5c. higher..

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)..................	3 65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Mar. 14, 1918	One Year One Year Ago	Mar. 14, 1918	One Year One Year Ago

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Fla., Christina—The Phosphate Mining Co. plans to rebuild its electric power plant which was recently destroyed by fire. P. H. Fuller, Nichols, Gen. Mgr.

Idaho, Dubois—The Dubois Light and Power Co., recently incorporated with $25,000 capital stock, plans to build an electric-lighting plant on Beaver Creek near here.

Ind., Richmond—J. P. Dillon, Supt. of the electric-lighting plant, has requested the City Council to appropriate $200,000 for an extension to the plant.

Kan., Bunkerhill—City is considering the erection of an electric-lighting plant.

Ky., Louisville—The Progress Laundry Co., 716-720 Broadway, plans to purchase electrical equipment including a 100 hp. engine.

Md., Baltimore—The Bartlett Hayward Co., Scott and McHenry St., has awarded the contract for the erection of a 28 x 49 ft. transformer house, to Morrow Bros., Fidelity Bldg.

Mass., Medfield—The Commission on Mental Diseases will soon receive bids for replacing main steam line to various buildings with large line and extensions. The work involves 3850 sq.ft. radiation, Jenkins valves, 240 ft. 1½ in. pipe mains to various building and large 3 in. steel pipe.

Minn., Lanesboro—City plans an election soon to vote on $15,000 honds for the erection of an electric-lighting plant. H. T. Asbre, City Clerk.

Miss., Clinton—City plans to install additional equipment in its power plant. Estimated cost, $8000. J. W. Provine, Mgr.

Mo., Concordia—The Trustees of St. Pauls College have plans under consideration for the erection of a new power plant at the institution. C. F. May, Merchants Laceled Bldg., St. Louis, Arch.

Mo., Kansas City—The Kansas City Light and Power Co. will build a 4-story, 185 x 244 ft. power plant on Front St. and Park Ave. A. N. Richardson, Gen. Supt.

Mo., Lewistown—H. H. Bronson is in the market for direct current generators.

Mo., Marshfield—The Marshfield Electric Co. plans to improve and alter its plant; a new generating unit will be installed.

Mo., St. Louis—E. W. Leverett, Supt. of the lighting system, is in the market for a generating unit and power plant equipment to replace 150 hp. equipment now in use.

N. Y., Brooklyn—The Arabol Manufacturing Co., 100 William St., New York City, is having plans prepared by H. Harlach, Engr., 451 East 144th St., New York City, for the erection of an addition to its boiler house on Sanford St., here.

N. Y., Buffalo—The Delaney Forge and Iron Co., 300 Perry St., is in the market for power plant equipment of about 500 hp.

N. Y., Buffalo—The Pullman Co., 79 East Adams St., Chicago, plans to purchase power plant equipment.

N. Y., Elmira—Hilliard Clutch and Machine Co., 4th St., plans to install a steam heating extension to its present plant. Electric motors will be purchased.

N. Y., Elmira—The Willys-Morrow Co., Toledo, Ohio, is in the market for power plant equipment.

N. C., Badin—The Tallassee Power Co. plans to build 200 additional buildings to its plant soon. G. R. Gibbons, Pittsburgh, Secy.

Ohio, Atwater—The Atwater Light and Power Co., incorporated with $10,000 capital stock, plans to build and operate an electric-lighting plant. E. P. and P. W. Whittlesey and others, interested.

Ohio, Cincinnati—J. A. Fay & Egan Co., John and Front Sts., will install power plant equipment in its proposed wood-working factory.

Ohio, Cleveland—City is in the market for 1333 electric meters ranging from 5 ampere, 110 volt single phase meter to 220 ampere, 110 volt potential transformers. E. Shattuck, City Purchasing Agent. R. Hoffman, City Engr.

Okla., Kingston—City plans to rebuild its electric-lighting plant which was recently wrecked by an explosion.

Penn., Philadelphia—The Cocoa Butter Manufacturing Co. has had plans prepared by A. F. Sauer & Co., Engr., 908 Chestnut St., for a new 1-story, 50 x 60 ft. brick power house to be erected at 2626 Martha St. Noted Mar. 12.

Wash., Bellingham—The Puget Sound Traction Co., Stuart Bldg., Seattle, plans to build a transmission line from here to the Cokedale Mine to furnish horsepower to the plant there. J. Harisberger, Gen. Supt.

Wash., Seattle—The City will build a power station for the lighting department at 14th Ave., N. W., and 49th St. The work will be done by day labor. Noted Jan. 22.

W. Va., Fireco—The Battleship Coal Co., Princeton, plans to build a central power plant at its mines, here. H. E. Hines, Pres.

Wis., Neenah—The City Council plans to purchase electric equipment for its stone quarry.

Ont., Hamilton—The Imperial Oil Co., 56 Church St., Toronto, has had plans prepared by J. L. Havill, Engr., for the erection of a pump house. Estimated cost, $5000.

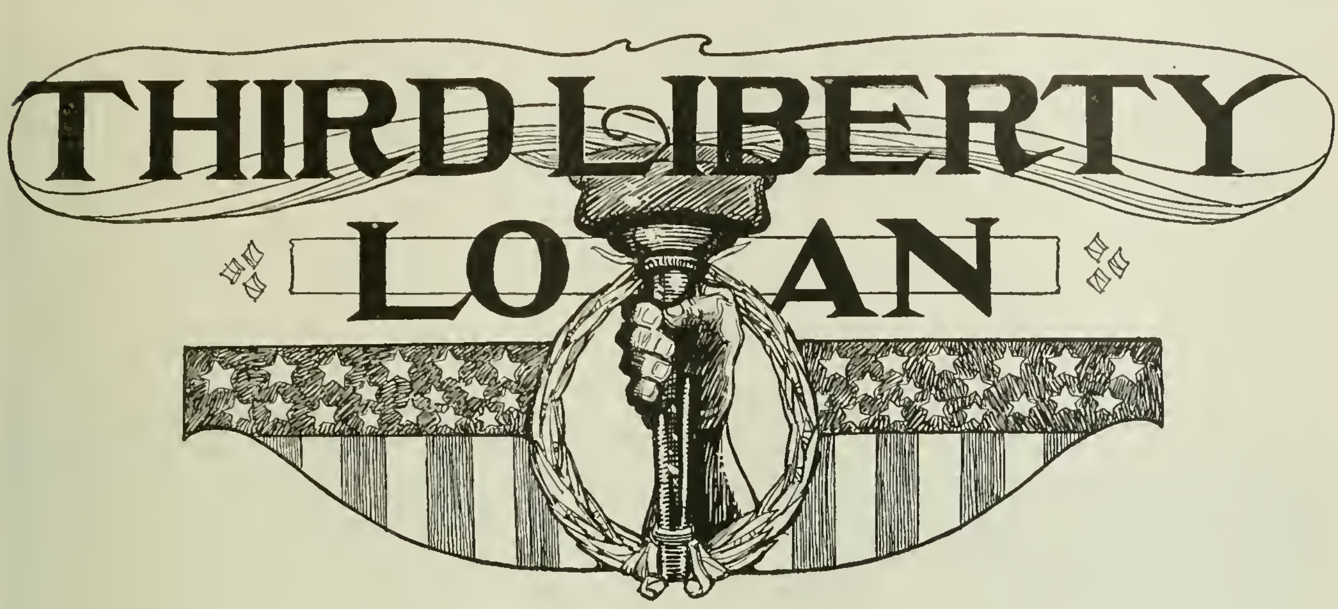
Ont., Port Dover—The Town Council plans to install a hydro system. J. Slian, Town Clk.

Que., Montreal—The Southern Canada Power Co., Coristine Bldg., is in the market for a 150 kw. and a 300 kw. motor generator set, second hand, the generator end 250 volts direct current, motor end 3 phase, 60 cycle, 220 volts synchronous motor, or separate machines of identical capacities and characteristics. L. C. Haskell, Purchasing Agent.

Que., Verdun—The Town Council will soon receive bids for repairing and reinforcing its electric-lighting and water works plants. Estimated cost, $50,000. G. A. Ward, Town Clerk.

POWER

Vol. 47 NEW YORK, MARCH 26, 1918 No. 13



The National Shibboleth

By RUFUS T. STROHM

We've long been a nation of prodigal spenders
With Luxury reigning and Wealth as her slave,
But now we must change to a nation of lenders,
For Uncle Sam needs every cent we can save.
It's time that we exercised judgment and gumption
And gave to our allies a powerful lift
By cutting out waste and decreasing consumption—
The patriot's watchword is personal thrift.

* * *

Because the expense every day runs to millions
In feeding and clothing and arming our men,
We've twice taken loans that were measured in billions,
And now we're required to do it again.
But though it may seem like a burdensome trial,
The end of it all will be certain and swift
If every true citizen learns self-denial—
The secret of winning is personal thrift.

We ought to be proud that the gold we are saving
In office and workshop, at roll-top and bench,
Is spent in behalf of the men who are braving
The hardships and dangers of billow and trench.
Though prices mount higher and war-bills grow longer,
The conflict will have but the shortest of shrift,
And people and nation be better and stronger,
If everyone practices personal thrift.

* * *

The ease-loving habit of "letting George do it"
Is criminal now and must go to the wall;
The country's at war, and to pull bravely through it
The cares and discomforts must rest on us all.
Extravagant ways are a species of treason
From which we should hasten to cut us adrift
And substitute carefulness, saneness and reason—
We'll win if we cultivate personal thrift.

Tamarack Mills Power Plant

By CHARLES H. BROMLEY

Describes the chief features of the new oil-burning plant furnishing light, heat and power to the Tamarack Mills, Pawtucket, R. I. The plant was designed solely for fuel, has a 2500 kw. extraction turbine, heats the mills with forced-circulation hot water and has the largest atmospheric cooling tower in New England. Unusually interesting performance figures are given.

PERHAPS no plant is today commanding more attention in New England than that of the new Tamarack Mills, Pawtucket, R. I., the turbine room of which is shown in Fig. 1. Certainly, no engineers were ever prouder of their plant than are Charles Teft, the chief engineer of the plant, and Jencks and Ballou, consulting engineers who designed it. To get a proper perspective of this power house one must go back to 1914, when the plant of the Jencks Spinning Co., alongside the Tamarack Mills plant, was using coal, and to 1916 when oil was introduced as fuel for this plant. With coal the results were:

	Per Ton
Fuel: Crozer-Pocahontas, 14,500 B.t.u., per lb	$4.40
Equivalent evaporation per lb. combustible, lb	12.33
Cost per 1000 lb. steam, cents.	18.2

When the change to oil was made, tests in 1916 with oil as fuel gave the following chief results, the costs including operating and overhead charges.

YEARLY SAVING WITH OIL.

Weekly kilowatt-hour output	195,400
Yearly kilowatt-hour output	10,160,000
Cost per kilowatt-hour output, exclusive of makeup water, cents	0.588
Cost per kilowatt-hour in 1913 with coal, cents	0.662
Difference in cost, cents	0.074
Yearly saving 10,160,000 × 0.00074	$7500

[Those interested who may want further cost and performance data are referred to two articles on this plant by the present writer in *Power* for Dec. 1, 1914, and Dec. 19, 1916.]

So when the Tamarack plant was proposed the management merely needed a contract for oil at a favorable price to immediately decide what fuel it should be built to burn. The management got a price of 92c. per bbl. of 42 gal. of oil, delivered and averaging as following: Moisture, 0.3 per cent.; sulphur, 3.56 per cent.; sediment, trace; specific gravity, 0.960; Baumé gravity, 15.9; flash point (closed cup), 178 deg. F.; fire point (open cup), 262 deg. F. The oil is a Mexican product. No one hopes now to close a long-term contract at this price. There is a 257,500-bbl. oil-storage station at Providence a few miles away, and oil from here is delivered to the Tamarack plant in cars. Now that the Fuel Administration controls fuel oil, one is interested to know how the contract is affected. Well, the mills are making Government war goods, and timely and adequate delivery is reasonably well assured at the contract price. The plant was designed for oil exclusively, no coal or ash-handling equipment being installed.

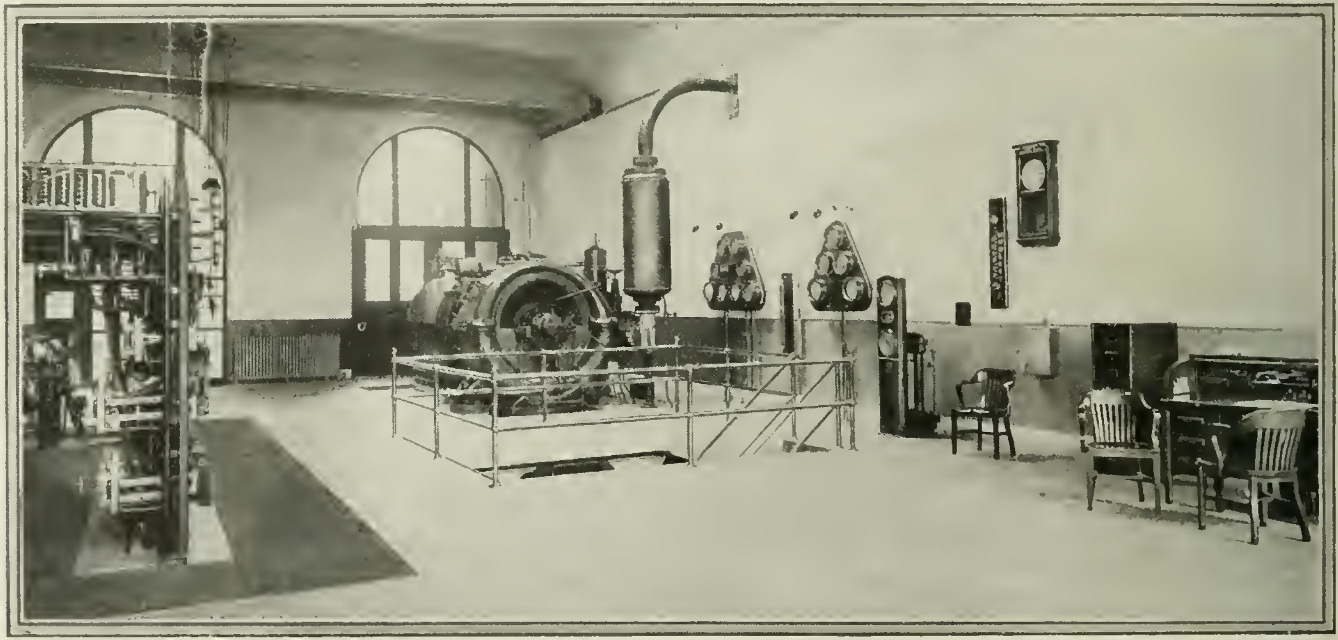


FIG. 1. VIEW OF TURBINE ROOM, TAMARACK MILLS, PAWTUCKET, R. I

The Tamarack plant consists of four water-tube boilers (B. & W. type) set with the bottoms of the front tube headers 8 ft. above the floor. Fig. 2 is a view of the boiler room. There are two furnace doors per boiler, and at each is a steam atomized (Hammel) oil burner, giving one burner for every seven tube headers. The burner produces a flat flame by reason of the impact of oil upon a renewable steel plate in each burner tip. Two oil-storage tanks, each of 24,000 gal. capacity, are used, the contents being kept at 115 deg. F. by live steam from the boilers admitted through reducing valves to pipe coil heaters in each tank. Exhaust steam from the oil-pumping outfit gives the oil a temperature of 160 deg. F. at the burner. This is 18 deg. F. below the flash point of the oil. The usual furnace draft carried is 0.2 in., the best boiler rating 40 to 50 per cent. above builders' rating, and the evaporation from and at 212 deg. F. per lb. of oil averages 15 pounds.

Throughout the plant the piping is one of the finest jobs the writer has ever seen. By great care in drawing up the specifications, the cost for extras was less than 1 per cent. of the total cost of the piping. A 16-in. lap-welded steel steam header is connected to the boilers by two 90-deg. bends (6-in. pipe) of 4 ft. radius each, having a nonreturn valve between each bend. Fig. 5 shows the exhaust piping at the spiral riveted free exhaust pipe.

All auxiliary exhaust is led to a 10-in. cast-iron main supplying exhaust steam to a closed feed-water heater of 900 sq. ft. heating surface. From the feed-water heater the 12-in. wrought-iron auxiliary exhaust main is continued to a back-pressure valve and then to the 24-in. spiral riveted free exhaust pipe. A tilting trap pumps water to a feed tank, from which the heated water enters the pump suction main. Two feed pumps are used, one a duplex 10 and 7 x 12-in., the other a three-stage centrifugal. The 6-in. discharge main is of cast iron and has a 4 x 1¼-in. venturi tube inserted in it. The branches to the boilers are of brass, and each branch has a "drop" pipe leading to each drum of each two-drum boiler. To avoid shock and pulsating flow, which would disturb the accuracy of the venturi feed-water meter, a large cast-iron air chamber is placed in the discharge main between the venturi tube and the pumps. Two-inch brass globe valves are used for controlling the feed to each boiler. The feed to the boilers averages 190 deg. F.

FIG. 2. OIL-BURNING BOILER ROOM, TAMARACK MILLS

The feed-water tank receives the condensate from the surface condenser attached to the main unit, also water from the turbine bearings and from the various drains throughout the plant. Fig. 3 is a view of the auxiliaries room.

The main four-stage turbine is of the extraction type, 2500 kw., 3600 r.p.m., 155 lb. steam pressure. Steam is bled from the second stage at from 1 to 10 lb. gage pressure for heating the water used for heating the mill buildings. More about the hot-water heating system later. The turbine is served by a surface condenser of 5000 sq.ft. As no adequate cheap water supply is available for condensing purposes an atmospheric cooling tower 20 ft. wide, 120 ft. long and 35 ft. high, handling about 5000 gal. of water per minute during cool weather, is used. The 12-in. circulating pump is of 4500 gal. per minute capacity, driven by a 95-hp. two-stage turbine. The discharge water goes to the cooling tower through an 18-in. pipe and returns to the pump suction through one of the same size. This tower has not yet had an opportunity to show what it can do under summer conditions, but judging what it will do based on winter operation, in the way of vacuum and cost of handling water, all concerned are indeed enthusiastic, especially Jencks and Ballou, the consulting engineers who designed the plant. The recording instruments are well arranged, as shown in Fig. 4. The main water connections to the tower are shown in Fig. 6.

The hot-water heating system is of considerable interest. Exhaustive investigations led to a decision between a vacuum steam heating system and forced hot-water circulation. The successful company bid on both, but guaranteed appreciably better economy for the hot-water system. The contract was awarded for the latter system. The essential facts are these: The mill is devoted chiefly to cotton spinning, and the main mill, of red brick, is 368 ft. long by 172 ft. wide, has four

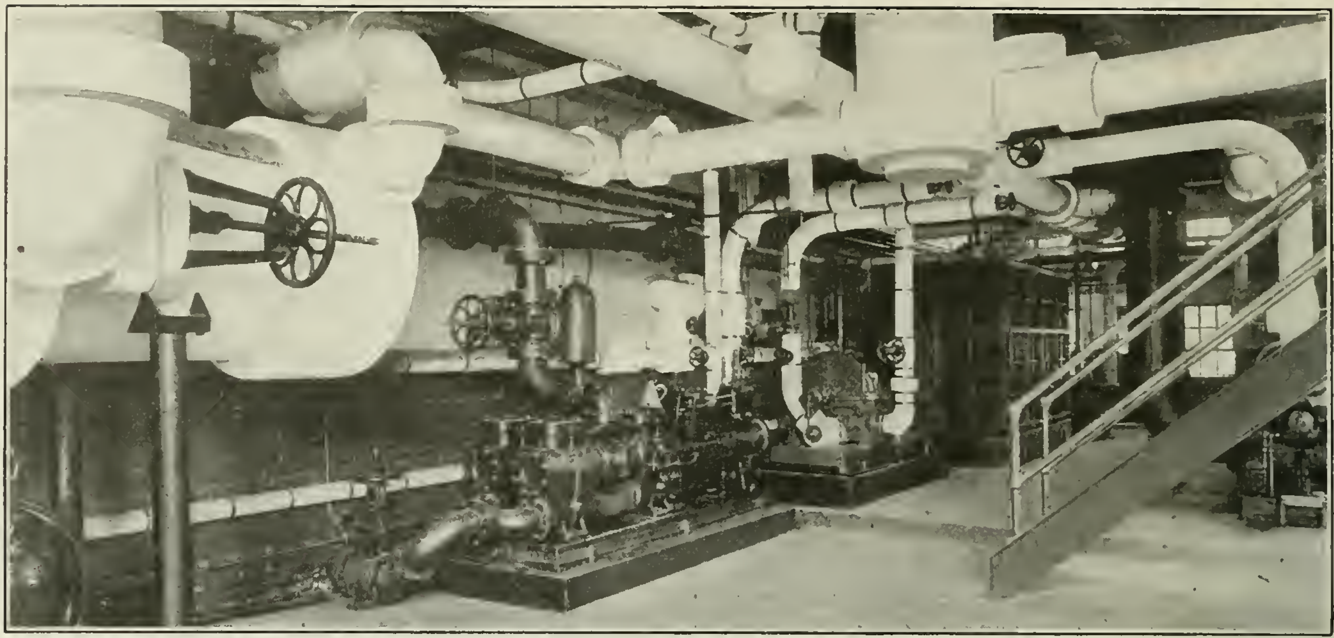

FIG. 3. ONE SIDE OF THE AUXILIARY ROOM, SHOWING PIPING AND FEED PUMPS

stories and a basement. The stories are high, ranging between 18 and 19 ft. The height of the basement varies between 8 ft. 8 in. and 13 ft. 8 in. The total floor area of the mill, including the basement, is 334,500 sq.ft., and the cubical content, including basement, is 5,720,000 cu.ft. Glass area, 43,320 sq.ft.; wall area, 40,000 sq.ft.; skylight area, 3870 sq.ft. These include three toilet towers. The radiating surface totals 22,800 square feet.

At the south end of the mill is a storehouse adjoining the power house. This structure is 78 ft. long by 172 ft. wide, the stories 9 ft. each except the first, which is 18 ft.+. The floor area is 47,200 sq.ft.; volume, 629,600 cu.ft.; glass area, 1980 sq.ft.; wall area, 6760 square feet.

For the mill, the ratio of heating surface to volume in cubic feet averages 1 to 251. The ratio varies of course for different parts of the mill, but ranges from 1 to 155 for the top story to 1 to 434 in the basement.

For the storehouse, the average ratio of radiating surface to cubic-foot volume is 1 to 547.

The radiating surface in the buildings is of 1¼-in. pipe in coils distributed overhead and on the walls beneath windows.

The main pipes extend from the mill through the storehouse and into the power house, where connection is made to the circulating pump. The latter unit is situated in the basement of the power house. The pump is of special design for this job and is direct-connected to the steam turbine. The pump has a 6-in. suction and a 5-in. discharge, and maintains a differential pressure between the suction and discharge of 25 pounds.

The steam turbine is supplied with steam at 150 lb. pressure and exhausts at a back pressure ranging from 1 to 5 lb. The exhaust from the turbine is led to the heater located in the storehouse. This is a straight tube heater of special design for this job, with capacity

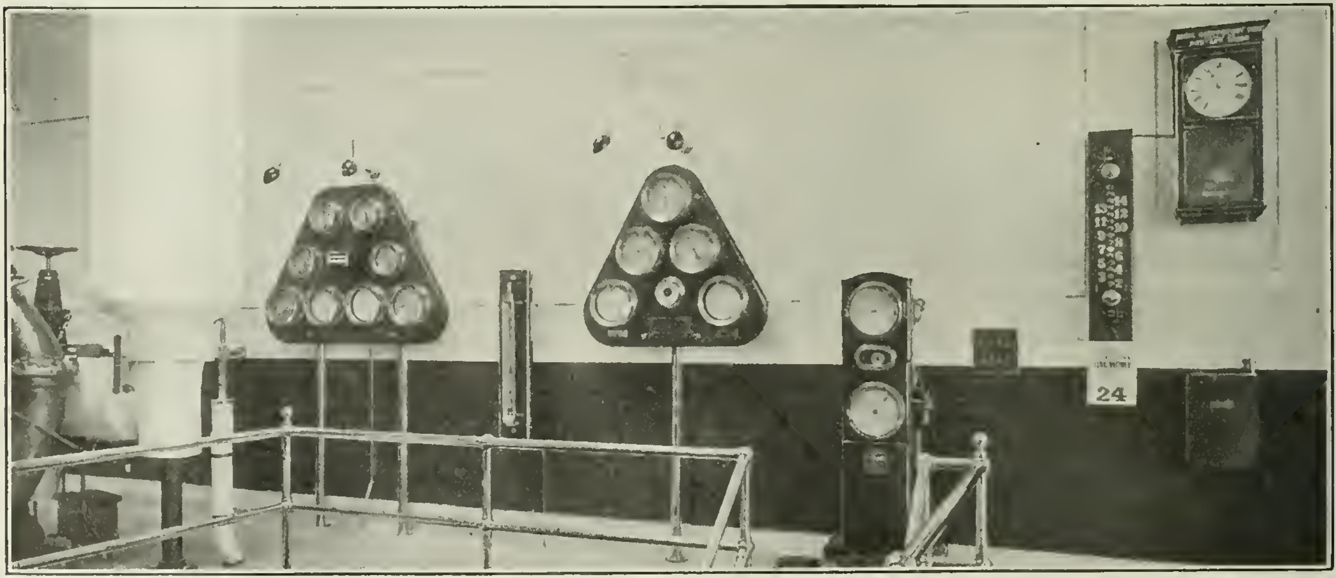

FIG 4 UNUSUALLY GOOD ARRANGEMENT OF RECORDING INSTRUMENTS

to maintain the flow temperature of water to any desired temperature ranging from 100 to a maximum of approximately 210 degrees.

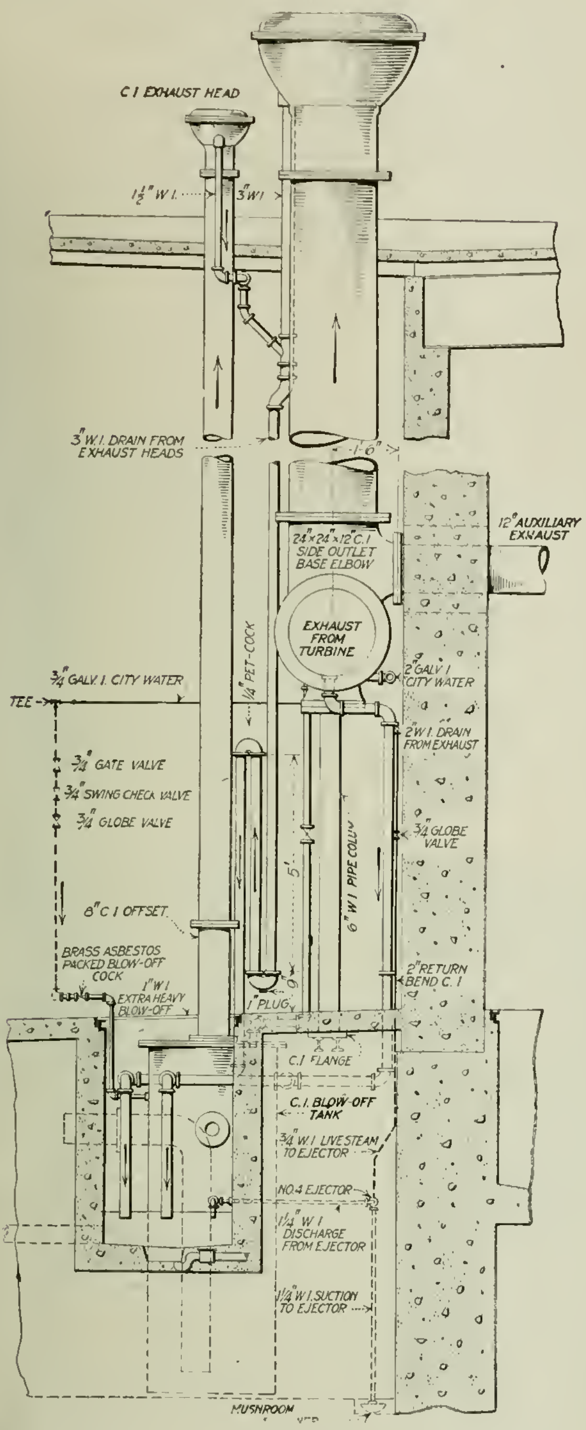

FIG. 5. EXHAUST AND BLOWOFF CONNECTIONS

The exhaust from the hot-water circulating pump turbine is also connected to the heater and there is a live-steam connection for use when the main turbine is not running. The hot-water circulating pump turbine is designed to give full capacity with steam pressure as low as 70 lb. Thus the boilers at night or on Sundays may vary in pressure considerably without interfering with the proper heating of the mill. The governor of this turbine is equipped with thumb-screw adjustment that will vary the speed of the pump from zero to maximum. In this way more or less water can be circulated, according to the flunctuating demands occasioned by the weather conditions.

The volume and pressure of the steam supply to the heater is controlled by hand to conform to the demands of the work in the mill, and to the outside temperature and other conditions. The pipe used is wrought steel. Long-turn fittings were used where the friction conditions made this advisable, but regular

fittings were used to a great extent, especially on the smaller sizes of pipe.

The system was designed to guarantee the following temperatures with outside temperature at 5 deg. below zero: Main mill, 65 deg.; toilet towers, 55 deg.; opening room, 60 deg.; storehouse, 40 degrees.

In the severe weather of this winter, with the temperature often lower than 10 deg. below zero, this system maintained satisfactory temperatures, thus exceeding the guaranteed temperatures.

Uniform circulation has been produced without any changes in the design of the piping since the system was first started.

This plant is commanding the attention of all New England, particularly that of the textile industry. Its performance portends much for the future of fuel oil in New England.

The water, light and power industry in January had 6 per cent. more employees and paid 5 per cent. more wages than in December. As compared with the corresponding month of one year ago, the group as a whole reported in January, 1918, an increase of 13 per cent. in the number of employees and 27 per cent. in wages.

In a paper read recently at Chicago, Major R. A. Millikan, professor of physics in Chicago University, stated that war was 85 per cent. science and engineering and 15 per cent. actual fighting. As one application of science he mentioned that it had proved practicable to locate the position of a heavy gun within 50 ft. by observations on the sound waves set up on its discharge.

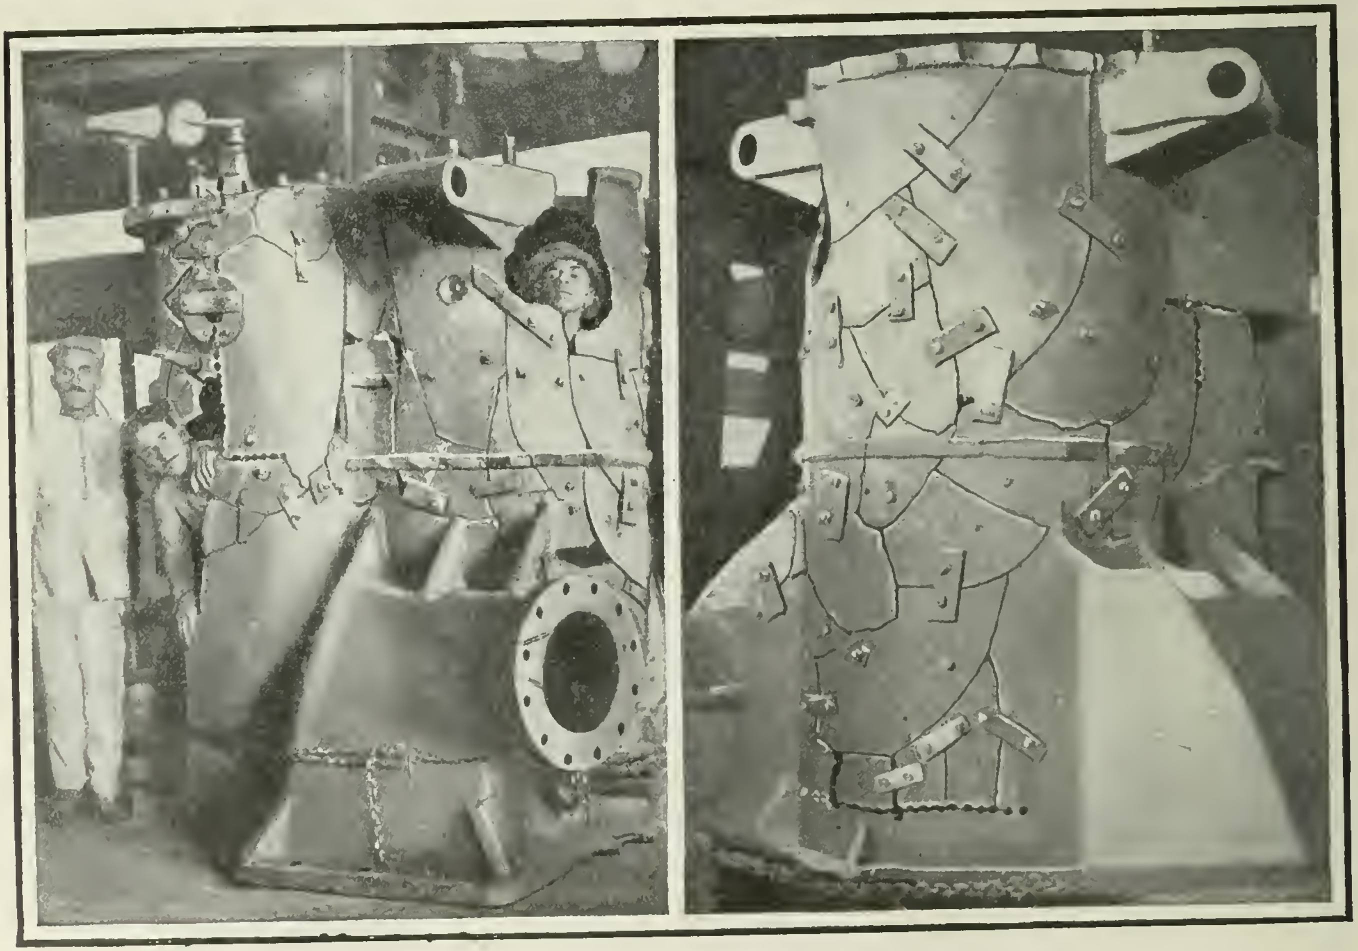
Kultur Mit Sledgehammer

The illustrations, reproduced from *Engineering* (London), show the damaged high-pressure cylinders of one of the German merchant ships interned in Brazil and illustrate the thoroughness of German destruction.

The 45 vessels which are interned, totaling 235,000 gross tons, had all been more or less seriously damaged, particularly the propelling machinery. In some cases new cylinders throughout had to be made; in others only portions of the cylinders had been destroyed. In one instance nearly 8000 holes must have been drilled in order to effect complete destruction. As it was found that the repair work could be carried out in the naval arsenal of Brazil, it was decided by the Ministry of Marine to proceed immediately with the recasting of the damaged cylinders and liners, and great credit is due to the engineering officers of the Brazilian Navy and to the personnel of the arsenal, not only for executing the work, but for the expedition with which it was carried out.

The cylinders illustrated had been broken into hundreds of small pieces, and in order to make new cylinders to suit the set it was necessary to assemble as many pieces as possible so that their dimensions could be measured accurately.

It is an interesting fact that most of the broken parts of the machinery were carefully stored between decks, evidently in order to be used as scrap in Germany in the event of the return of the ships to the "Fatherland."



WHAT "SCHRECKLICHKEIT" DID TO AN INTERNED GERMAN STEAMER IN BRAZIL

Distinguished Engineers of New England

New England is the home of many distinguished engineers. It was there that George H. Corliss made his engine, which became a famous type. E. D. Leavitt, of Boston, had become a distinguished engineer before he died, and among the boys that Leavitt had in his office some are today holding positions of appreciable magnitude. Edwin Reynolds, who designed the last of the great reciprocating engines, was a New Englander. And there are so many others who have "drunk their cup a round or two before and one by one crept silently to rest" that it is regrettable that space here does not permit of saying something about them and others, who, fortunately, are living. There follow brief sketches of some engineers in New England who are well known for their interest in and contributions to the art.

CHARLES T. MAIN

CHARLES T. MAIN, Boston, President of the American Society of Mechanical Engineers, was born in Marblehead, Mass., Feb. 16, 1856. He is a graduate of the Massachusetts Institute of Technology, and after graduation was an assistant in the department of mechanical engineering in that institute. In the late 70's he became draftsman for the Manchester Mills, Manchester, N. H. Later he became engineer for the Lower Pacific Mills, Lawrence, Mass.; in 1886 he became assistant superintendent, and in July, 1887, was made superintendent.

In all Mr. Main put in eleven years in these mills, having charge of all engineering and of the reorganization and operation of the mechanical department. After a year in Providence, R. I., he formed an association with F. W. Dean, whose photograph, by the way, should appear here were it not that Mr. Dean is serving the Government and unavailable at this writing. These engineers became famous for their textile-mill work, which later extended to general engineering. The association lasted for fourteen years, or from 1893 to 1907. The small waterwheel installations grew to great hydro-electric projects. Mr. Main has engineered four hydro-electric developments aggregating 280,000 hp. for the Montana Power Co. He is president of the Engineers' Club, Boston; member of the American Institute of Consulting Engineers; Boston Society of Civil Engineers, and other technical societies. He became a member of the American Society of Mechanical Engineers in 1885, served as manager for three years, and was elected president at the last yearly meeting in December, 1917. He has long been active in public life. As president of the American Society of Mechanical Engineers he is sure to play a laudable part in America's war against the Hun. The society has been called upon by the Government to assist in solving many knotty problems related to the war, and it is fortunate that a man of Mr. Main's capacity and experience is guiding the society through these propitious times for the engineer.

JOHN R. FREEMAN

JOHN R. FREEMAN, Providence, R. I., is, perhaps, New England's most distinguished engineer. Born in West Bridgeton, Me., July 27, 1855, he graduated from "Tech" in 1876. In 1904 Brown honored him with the degree of Sc.D., and Tufts' did the same in 1905. From 1876 to 1886 he was engineer with the Water Power Co., Lawrence, Mass.; from 1878 to 1886 assistant consulting engineer to Hiram F. Mills, and for the following ten years chief engineer, Associated Factory Mutual Insurance Co. He was also consulting engineer on water supply and mill construction for various corporations and for New York, Boston, Los Angeles, Baltimore and San Francisco. He was civilian engineer, Supplies Board, War Department, in 1902; advised on the Panama Canal locks and dams and for the Canadian government on water-power conservation. He is trustee of the Massachusetts Institute of Technology; was president (1893), Boston Society of Civil Engineers, vice president (1902), American Society of Civil Engineers, president (1905), American Society of Mechanical Engineers, member Providence Chamber of Commerce and fellow of the American Academy of Arts and Sciences. In 1899 he made extensive investigations of New York City's water supply; he was chief engineer of investigations for the Charles River Dam, Boston Harbor, in 1903, and in 1903-4 was consulting engineer on drainage and sanitation for the Boston Metropolitan Park Commission. He planned the hydro-electric development on the Feather River, Calif., in 1905, also developments along the St. Lawrence and Long Sault. He was in charge of the water-power investigations of the New York State Water Supply Commission. At one time he was a member of the Water Commission of Winchester, Mass. Mr. Freeman has always been active in general business and financial matters, being president of the Manufacturers, Rhode Island, Mechanics, State, Enterprise and the Associated Factory Mutual Insurance Companies; director Rhode Island Trust Co., Providence Gas Co.

DR. IRA N. HOLLIS, Worcester, Mass., is the President Wilson of the American Society of Mechanical Engineers. His utterances when president of the society are full of the same lofty, substantial vision and comprehension of events in engineering as President Wilson's are of the changing social fabric. Born in Mooresville, Ind., 1856, he graduated from the Louisville, Ky., high school, took up the machinist's trade and later entered the United States Naval Academy. He served on cruisers "Quinnebang," "Alert," "Hartford," "Richmond" and "Charleston." In 1884 he was a member of the advisory board that designed the ships of the famous White Squadron. Following this he served under the late Admiral Melville, chief engineer, United States Navy. In 1893 he resigned to become professor of engineering, Harvard University, where he remained for twenty years or until he became president of Worcester Polytechnic Institute. Since the outbreak of war Dr. Hollis has been of most valuable assistance to his Government in engineering problems of the war.

DR. IRA N. HOLLIS

PROF. EDWARD F. MILLER is one of the most widely known men in the field of power-plant engineering. He is head of the Department of Mechanical Engineering, Technology, which department is maintained by Harvard University and the Institute; he is also director of the engineering laboratories of "Tech," from which he graduated in 1886. He planned the greatest part of "Tech's" new engineering laboratories. He is a master at harnessing theory and practice to give the best teamwork. The engineer officers now instructed by him for the Shipping Board's merchant marine will swear to that. He is author of valuable engineering literature. Professor Miller is a member of the American Society of Mechanical Engineers, American Society of Refrigerating Engineers, American Society of Civil Engineers, American Academy of Arts and Science, Boston Society of Civil Engineers, and honorary member of the National Association of Stationary Engineers. He is Chief Instructor in Engineering for the Shipping Board, member Boiler Code Committee.

PROF. EDWARD F. MILLER

GEORGE HALE BARRUS, of Boston, is closely identified not only with the development of power as applied particularly to the textile and paper industries of New England, but with its development nationally. He is a graduate of the class of '74, Massachusetts Institute of Technology. Mr. Barrus has conducted investigations and experiments in steam engineering for the United States Navy and for marine purposes generally. Under the late and well-known Prof. Channing Whitaker he supervised the erection of the steam-engineering laboratory of old Technology, the first of its kind in the United States. His works on boiler and engine tests are known internationally, and he is chairman of the power-test committee of the American Society of Mechanical Engineers. Mr. Barrus was vice president and member of Council of that society from 1905 to 1906; is a member of the Boston Society of Civil Engineers, New England Water Works Association, Society of Naval Architects and Marine Engineers, Bostonian Society, Engineers' Club of New York and the Technology Club.

GEORGE H. BARRUS

JOHN A. STEVENS, Lowell, Mass., was born in Galva, Ill., 1868. He left school at the age of 7, but later graduated from the East Saginaw, Mich., high school, and spent a year at the University of Michigan. He served as machinist in the Pere Marquette Railroad shops, and as engineer on the Lake steamers, "Sappho," "Byron Whittaker," "W. H. Stevens," "Roman" and "Cambria." At 27 he held a marine engineer's unlimited license, and was engineer on the ocean steamships "Indiana," "Illinois," "New York," "St. Louis" and "St. Paul." In 1896 he became chief engineer, Merrimack Manufacturing Co., Lowell, appointed to the Massachusetts Board of Boiler Rules by Governor Curtis Guild in 1907, reappointed by Governor Draper in 1910, studied European engineering practice in 1909 and later engaged in consulting work, appointed chairman Boiler Code Committee, A.S.M.E., in 1911, and to his dynamic personality the Code owes much for its success. He was one of the early users of stage and exhaust steam from turbines; one of two inventors of a 25,000 hp. water-tube boiler.

JOHN A. STEVENS

I. E. MOULTROP, Boston, widely known in engineering circles, began his career as an apprentice machinist with the Whittier Machine Co., later to become that company's chief draftsman. Twenty-six years ago he resigned this position to go with the Boston Edison Co., with which he has served ever since. His first job with the Edison company was to lay out and install the steam equipment for the old Atlantic Avenue Station, commonly known as the third station. Since then he has grown with the development of power generation and transmission. For some years he has been assistant head of the construction bureau of the Edison company, directly responsible for work of all character on power stations, substations, office buildings, etc., and indirectly responsible for the construction of the transmission lines, underground and overhead. Mr. Moultrop has been manager and vice president of the American Society of Mechanical Engineers, and for five years was chairman of the membership committee of that society; he also serves on the Boiler Code Committee. He is a prominent member of the National Electric Light Association.

I. E. MOULTROP

WALTER A. DIMAN, Manchester, N. H., is the son of George H. Diman, consulting engineer, American Woolen Co. Born in Woonsocket, R. I., 1879, he was educated in the public schools, Lawrence, Mass.; entered the Naval Academy, Annapolis, September, 1898, graduated in 1902; performed service in the Navy at the Asiatic Station from 1902 to 1905, when he returned for duty at the Bureau of Steam Engineering, Navy Department, Washington, D. C. After a tour of duty here he was detailed as engineer officer of the President's yacht "Mayflower," returning to duty at the Bureau of Steam Engineering; detailed for duty at the Naval War College, Newport, R. I., and then transferred in 1910 as engineer officer of the U. S. S. "New Jersey." He resigned from the Navy October, 1911, to become superintendent of power, Amoskeag Manufacturing Co., Manchester, N. H. He is a member, American Society of Mechanical Engineers, the American Society of Naval Engineers and belongs to several clubs.

WALTER A. DIMAN

GEORGE A. LUCK, chairman, Massachusetts Board of Boiler Rules and chief of the commonwealth's Boiler Inspection Department, was born in London, Eng. He served his apprenticeship to the machinist's trade there, and when a young man came to America. One of his first jobs was as watch engineer in the old Boston Electric Light Co. That was when the electrical industry was still in swaddling clothes. Later, he was engineer for the Reece Buttonhole Machine Co., Boston, the Franklin Brewery, Boston, and later became engineer for the Hamilton Mills, Amesbury, Mass. Following this he went to Chicopee to take charge of the power plant of the Dwight Manufacturing Co. In 1906 he took the civil-service examination for state boiler inspector, and in September, 1907, was appointed, together with five others, a law having passed the legislature increasing the number of inspectors from ten to fifteen. Joseph McNeil was then chairman of the Board of Boiler Rules and chief boiler inspector. Mr. Luck was assigned to the district embracing the suburbs of Boston. In July, 1912, he became acting chief and chief in June, 1914.

GEORGE A. LUCK

WALTER H. DAMON, superintendent of power generation, United Electric Co., Springfield, Mass., typifies the purposeful, persistent New Englander. Compelled to face the world practically alone before he could with dignity wear long pants—at 11, to be exact — he has fought a long fight, and won. Like most boys whom the Fates have cast up and would make of them derelicts, young Damon tried his hand at various things until one momentous day he got a job wheeling coal into the little boiler room of the United Electric Co. That was twenty-six years ago. He had not been on the job long before he got his hands on—well, it was a copy of *Power*. Friend Walter says the world unfolded. Mr. Damon is a member of several engineering societies, including the American Society of Mechanical Engineers and the National Electric Light Association. He has held most of the chief offices in the National Association of Stationary Engineers; he was elected national president of this association in 1915.

WALTER H. DAMON

FRANK W. TOWNSEND, of Providence, R. I., is a chief operating engineer of the new school. Born in the country, he was always fascinated by the blacksmith shop and the thumping engine down at the old stone mill. He laid the foundation for ability as an operating engineer by getting machine-shop experience at the start. He attended night school and studied hard the few engineering books that came his way. Then came a job in a machine shop doing marine work. Of course he soon went to sea, started somewhere in the stoke-hole and after seven years had his marine chief engineer's unlimited license and commanded the mechanical equipment of a large ship. Not that swimming through bilge-water to start a balky pump took the romance from a ship's engine room, no, that is what gives it; but the shore had a stronger call. He is now chief engineer of the famous South Street Station, Narragansett Electric Lighting Co., Providence, an 80,000-kw. turbine plant having a 45,000 kw. compound turbine.

FRANK W. TOWNSEND

EDWARD H. KEARNEY is one of the best-known operating engineers in New England. Born in North Billerica, Mass., he graduated from the Howe Academy there, later serving three years as apprentice machinist. His apprenticeship served, he put in four years as journeyman and erecting engineer, and completed the four-year course in mechanical drawing in the night schools of Boston. He served as instructor in steam engineering for three years in Franklin Union, Boston. He held the position of assistant chief engineer for the Jordan Marsh Co.'s large department store, Boston, and for twenty years he has been chief engineer for the John Hancock Mutual Life Insurance Co. In the N.A.S.E. he has held the following important offices: state deputy for Massachusetts, chairman state educational committee, national vice president in 1911, national president in 1912 and secretary of the national educational committee in 1913, 1914, 1915 and 1916. Mr. Kearney has contributed largely to the technical press.

EDWARD H. KEARNEY

New England's Water Power

Most of the interesting figures relative to New England's water power which follow are given by Henry I. Harriman, of Chace & Harriman, Boston: In New England there are eight large rivers having considerable fall: Penobscot, 1500 ft.; Kennebec, 1000 ft.; Androscoggin, 2200 ft.; St. Croix, 400 ft.; Saco, 1900 ft.; Merrimac, 269 ft.; Connecticut, 2000 ft. and the Housatonic with 900 ft. These rivers drain 35,000 of the 60,000 square miles of New England. The Bureau of Corporations estimates that 600,000 hp. of water energy is now in use in New England and that these same developments can be improved to give 200,000 hp. additional. The minimum water power capable of development is placed at 1,000,000 hp., with a possible 2,000,000 hp. In developed and undeveloped water power Maine has nearly 1,000,000 hp.; New Hampshire, Vermont and Massachusetts, 200,000 to 300,000 hp. each; Connecticut, 160,000 hp. and Rhode Island, 16,000 hp.

The present water-power developments in New England total more than two billion kilowatt-hours.

Most large New England streams vary greatly in their maximum and minimum flow. At the Vernon plant, Connecticut River Power Co., the variation is from 1500 cu.ft. per sec. to 150,000 cu.ft. per sec., or 100 times the minimum. The extremely low flow occurs on relatively few days, and in an average year the plant has sufficient water to carry full load for nine months.

Among the large hydro-electric developments in New England are the plant of the Rumford Falls Power Co., on the Androscoggin at Rumford, Me.; the plant of the Androscoggin Power Co., on the same river, near Lewiston; the plants of the Cumberland County Power and Light Co., on the Saco River, near Portland; the plants of the Bangor Railway and Electric Co., near Oldtown and Ellsworth; the plants of the Central Maine Power Co., near Waterville; the plant of the Turners Falls Co., on the Connecticut River at Turners Falls, Mass.; the plant of the Connecticut Power Co., on the upper Housatonic; the plant of the Connecticut River Power Co., on the Connecticut River near Brattleboro; and the plants of the New England Power Co., on the Deerfield River. These various plants have an aggregate capacity of about 250,000 hp. Nearly all of them have been constructed within the last five years and indicate the rapidity with which our streams are being utilized and their energy transmitted to distant cities and towns.

Considerable progress has also been made in the development of storage and the consequent conservation of the flood waters of the spring. A dam at the outlet to Moosehead Lake impounds a total in excess of thirty billion cubic feet and is capable of more than doubling the minimum flow of the Kennebec River at Augusta. Storage reservoirs on the Rangeley Lakes and in the upper waters of the Androscoggin have assured a minimum flow of 2000 sec.-ft. at Rumford Falls and Lewiston, and a reservoir created in Somerset, Vt., is now storing enough water to produce in existing plants approximately 25,000,000 kw.-hr. which would otherwise be wasted.

Training Engine-Room Crews for America's New Ships

By HENRY HOWARD

Director of Recruiting Service, United States Shipping Board, Custom House, Boston.

WITH the recent putting into commission at Boston of the first of a squadron of training ships for training men to man the new Government-owned cargo fleets, the United States Shipping Board Recruiting Service has greatly increased its activities. It is planned to train 25,000 Americans, 21 to 30 years old, for sailors, firemen, coal-passers, oilers, watertenders, cooks and stewards in the new merchant marine.

There are now two training ships in commission at Boston, the "Calvin Austin" and the "Governor Dingley," formerly in the coastwise passenger trade. Each is a 3800-ton ship, having reciprocating engines of 2700 hp. Each ship accommodates from 500 to 600 apprentices, divided between the engine department, the deck department and the steward department. A third ship, the former Army transport "Meade" will soon be ready.

SOME OF THOSE WHO ARE HELPING AMERICA TO MAN HER SHIPS

Front Row (left to right)—Capt. Eugene E. O'Donnell, Supervising Inspector, Fifth District, U. S. Steamboat-Inspection Service; Capt. Robert M. Lavender, National Trustee, American Association of Masters, Mates and Pilots; Henry Howard, Director of Recruiting, United States Shipping Board; William S. Brown, National President, Marine Engineers' Beneficial Association; Capt. Arthur N. McGray, Secretary-Treasurer, Neptune Association, also representing the Masters, Mates and Pilots of the Pacific Coast.

Middle Row—Capt. Ulster Davis, National Trustee, American Association of Masters, Mates and Pilots; Capt. Luther B. Dow, Business Manager, American Steamship Licensed Officers Association, Inc.; George W. Willey, Business Manager, Marine Engineers' Beneficial Association, No. 59, of Boston; James J. Raftery, Jr., President, Marine Engineers' Beneficial Association, No. 59, of Boston; Capt. Irving Sparks, Boston Agent, Neptune Association.

Back Row—Winfield M. Thompson, Field Agent, U. S. Shipping Board Recruiting Service; Edward Clarence Hovey, Jr., Chief, Sea Service Bureau; Bert L. Todd, Secretary, Ocean Association of Marine Engineers; Thomas A. King, Chairman Board of Directors, Ocean Association of Marine Engineers; Henry G. Vaughan, Sea Service Bureau; Edward F. Flynn, Assistant to Director of Recruiting, U. S. Shipping Board.

Apprentices accepted for training are taken only after careful physical examinations. They sign an agreement to serve in the merchant marine for the duration of the war. It is expected that most of them will win promotion and remain in the service many years after peace is restored, for the United States is to maintain its rightful place among foremost maritime nations. Opportunities for advancement will be many.

Here is the program established for the men in training: 6 a.m., all hands tidy room; 7 a.m., breakfast; 8 a.m., general work; 9:30 a.m., discipline and instruction; 10 a.m., inspection; 10:30 a.m., boat drill; 11:45 a.m., clean up; 12 noon, dinner; 1 p.m., fire drill; 2 p.m., seamanship; 3 p.m., boat drill; 4 p.m., general work; 4:45 p.m., clean up; 5 p.m., supper; 6 p.m., muster and liberty; 6-9 p.m., recreation, bathing, etc.; 9 p.m., all lights out. There is one instructor for every ten apprentices.

The plan of training inexperienced young men on training ships evidently hit a popular chord from the first. In 48 hours after the announcement was publicly made that the "Calvin Austin" had been chartered as a training ship, more than 500 applications for enrollment on her were received at the national headquarters of the United States Shipping Board Recruiting Service at the Boston Custom House. Only American citizens are accepted for the training ships. All the instructors are American seaman to man American ships. The apprentices are paid $30 a month while training. The course is five to seven weeks.

Since the summer of 1917 the United States Shipping Board Recruiting Service has successfully trained engineer officers for the new merchant marine, finding its material among men already experienced as assistant engineers, firemen, oilers and watertenders. This work has been carried on at schools conducted by the Shipping Board at eight leading technical institutions in different parts of the country, with Prof. Edward F. Miller, of the Department of Mechanical Engineering at Massachusetts Institute of Technology, as chief instructor in engineering. The schools will continue until a sufficient number of officers are trained for the new Government-owned cargo ships.

The free Government Schools conducted by the Shipping Board are located at the Johns Hopkins University, Baltimore; Massachusetts Institute of Technology, Cambridge; Armour Institute of Technology, Chicago; Case School of Applied Science, Cleveland; Stevens Institute of Technology, Hoboken; the Tulane University, New Orleans; The Bourse, Philadelphia; and the University of Washington, Seattle.

The course ordinarily lasts about four weeks. Instruction is free to those who qualify for admission, but students have to pay their own living expenses. On graduating from an engineering school, a student goes to sea for two months' special training as a junior officer at $75 a month, if necessary. He is then free to go into the merchant-marine service at prevailing rates of wages.

The Shipping Board Recruiting Service conducts a Sea Service Bureau, with headquarters at the Boston Custom House and branches at other ports, for placing its graduates. This service is free.

Ever since the Recruiting Service was established, it has conducted free Government navigation schools for the training of experienced seamen as deck officers. Forty-one of these schools have been established, from the Atlantic to the Pacific, wherever the demand seemed to justify them. The enrollment headquarters for all the United States Shipping Board Recruiting Service activities are at the Custom House, Boston.

These may qualify for training as chief engineer, ocean-going, in a Shipping Board engineering school: First assistant, one year, ocean or coastwise steam vessels; second assistant, two years, ocean or coastwise steam vessels; fireman, oiler or watertender of three years' engine-room service, ocean or coastwise steam vessels, may qualify as chief on ocean steamer of 500 tons or under; chief, one year, lake, bay or sound; first assistant, two years, lake, bay or sound.

These may qualify as first assistant engineer, ocean-going: Second assistant, one year, ocean or coastwise steam vessels; fireman, oiler or watertender of three years' engine room service, ocean or coastwise steam vessels, may qualify as first assistant, 1000 tons or under; first assistant, one year, lake, bay or sound; second assistant, two years, lake, bay or sound; apprentice to machinist trade, with three years' service on marine, stationary or locomotive engines and one year at sea; graduate in engineering, nautical schoolship, with six months at sea; graduate in mechanical engineering at a technical college, with six months at sea; locomotive engineer, two years, with one year at sea; stationary engineer, two years, with one year at sea.

These may qualify as second assistant engineer, ocean-going: Third assistant, one year, ocean or coastwise steam vessels; chief, six months, lake, bay or sound; first assistant, six months, lake, bay or sound; second assistant, six months, lake, bay or sound; third assistant, one year, lake, bay or sound; stationary engineer in full charge of a 1000 hp. plant; locomotive engineer, one year, and six months at sea; stationary engineer of plant of less than 1000 hp. who has had six months at sea; apprentice to the machinist trade who has had six months at sea; graduate in mechanical engineering at a technical college, with three months at sea;[1] graduate in engineering, nautical schoolship, with three months at sea.[1]

These may qualify as third assistant engineer, ocean-going: Fireman, three years; oiler or watertender, two years (or combined service of two years in these grades), ocean or coastwise steam vessels; chief, six months, lake, bay or sound; assistant, six months, lake, bay or sound; graduate in engineering, nautical schoolship; chief, one year, river; assistant, one year, river; journeyman machinist who has been engaged in construction or repairs of marine engines.

Increasing the Life of Economizers

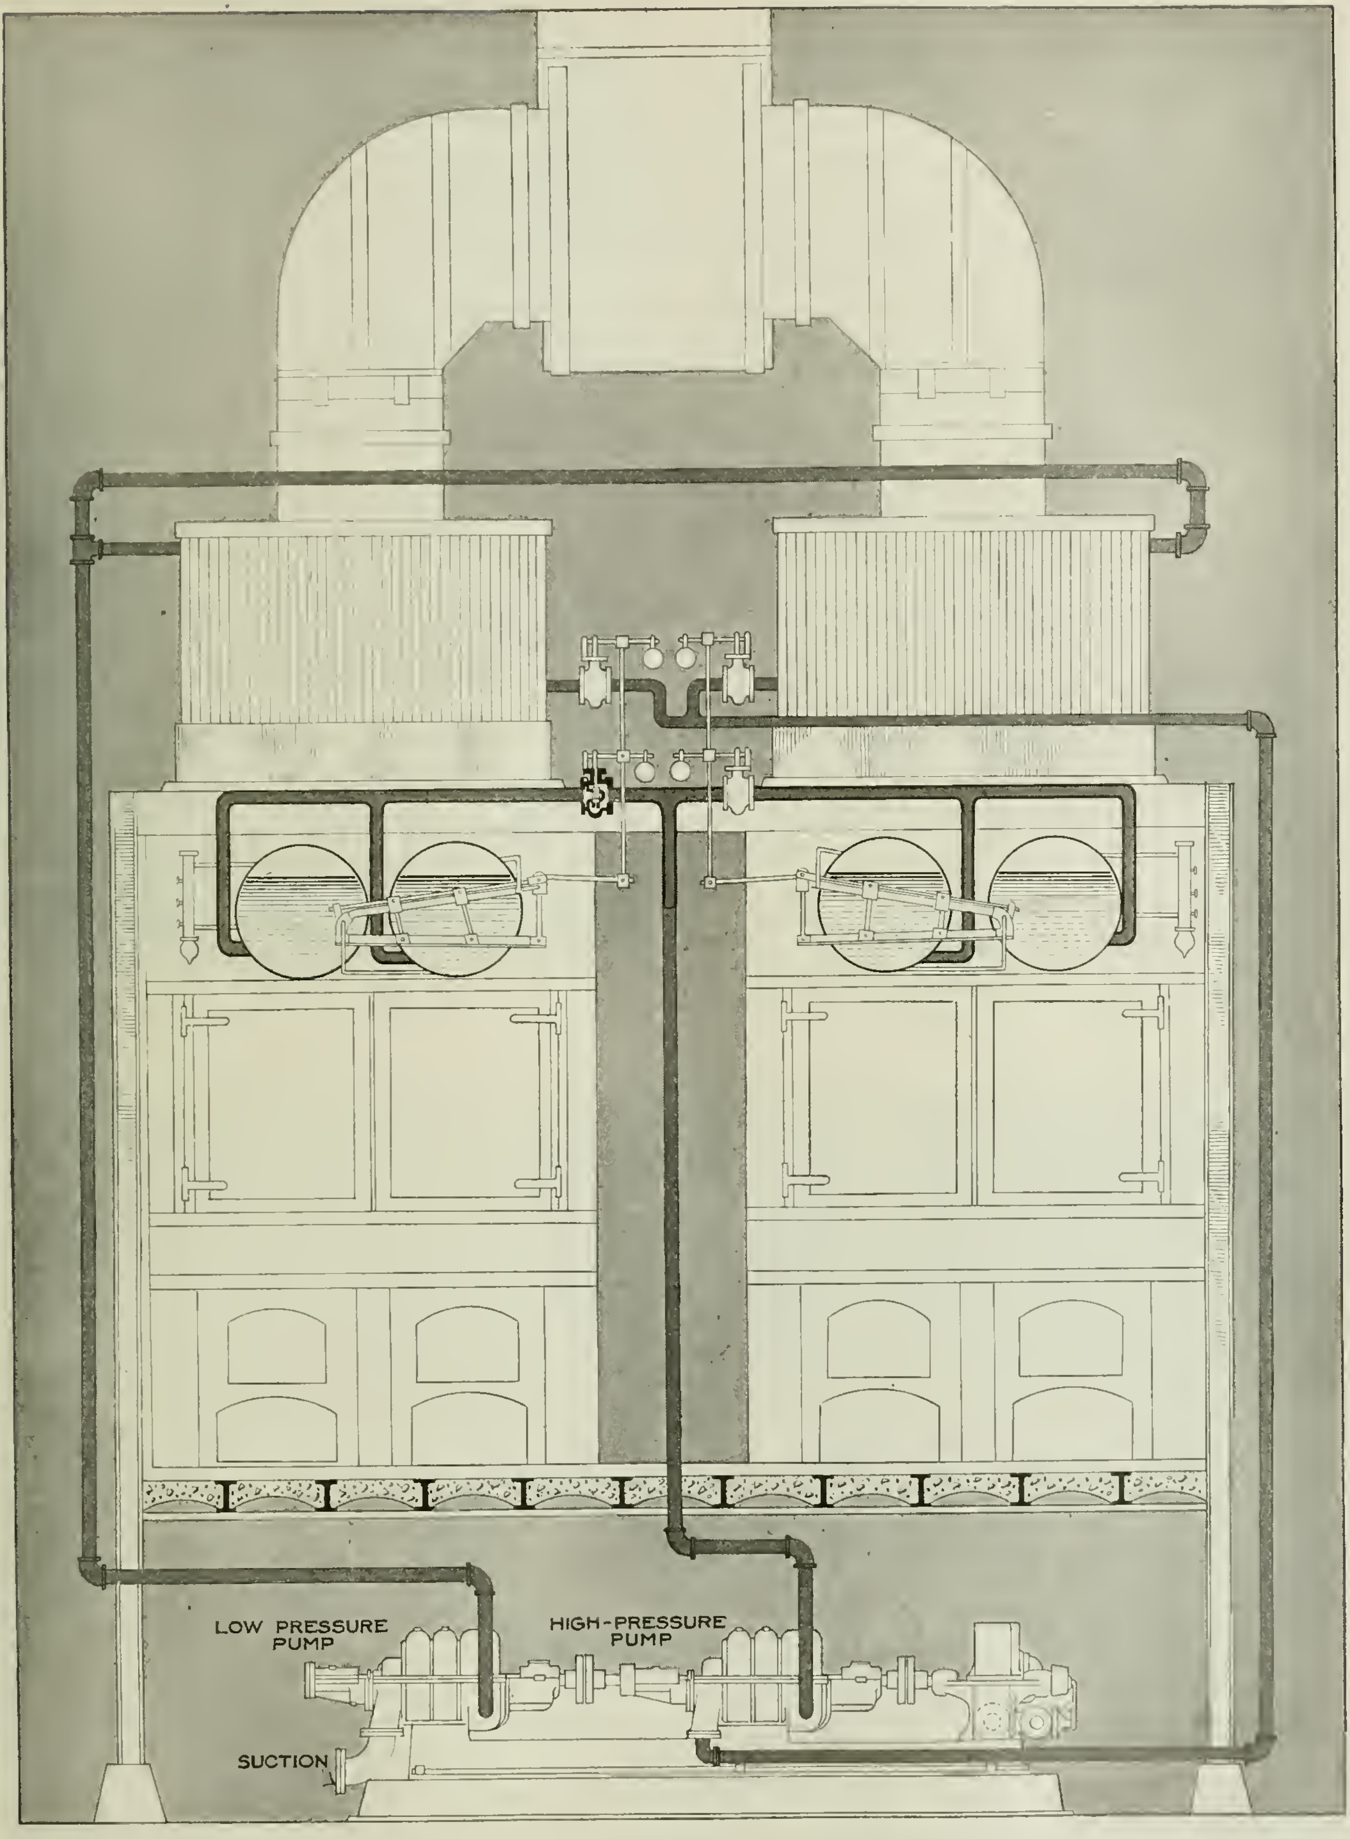
Throughout New England particularly, the average life of an economizer may be estimated as about 18 years. During this time, because of internal and external corrosion, there is a gradual thinning down of the walls of the headers and tubes. How serious this becomes depends upon the local conditions in each case, but on the average it may be assumed that the walls of the tubes become so thin that they are liable to fracture after the economizer is about 13 or 14 years old. This liability to fracture is greatly increased by any sudden shock, such as a water-hammer.

After a period of 16 or 17 years the walls of the tubes become so thin that it is impracticable to carry the usual high boiler pressure. To overcome this difficulty C. W. E. Clark, of Boston, and J. V. Santry, of Schumaker-Santry Co., Boston, have patented the application of a three-stage centrifugal pump in connection with these older economizer installations. The water is pumped from the primary heater through one stage of the pump to the economizer at about 40 to 50 lb. pressure, then from the outlet of the economizer to the suction of the second stage of the pump, the pressure being increased to the required boiler pressure. So far as the writer knows, George Diman, of Lawrence, Mass., was the first to propose this method of feeding water to economizers.

The application of this type of pump has materially increased the life of several economizer installations. In one case where the repairs had become excessive a pump of this type was installed and the pressure cut down from 175 lb. to 40 lb. This prolonged the life of the machine for a period of four years, and practically all the repairs due to tube and header fractures were eliminated during this period. The accompanying illustration shows all this so plainly that further description is unnecessary. During these times of high fuel costs and fuel shortage this method of feeding the water should effect worth-while savings in any plant where the economizer is out of service because it will not stand boiler pressure, but would hold if the pressure were reduced. The advantage of feeding, as shown in the full-page illustration, is that no boiler will "rob" the other of water; each will take what it needs without interfering with the other's supply.

---

[1] This three months' service at sea may be obtained after graduation from the school and before taking United States Steamboat-Inspection Service examinations, for license as an officer



FEEDING WATER AT LESS THAN BOILER PRESSURE TO OLD ECONOMIZERS AND REGULATING FLOW AS REQUIRED TO EACH BOILER AND ECONOMIZER

Foreign Substances in Coal

The photograph, Fig. 1, shows of a pile of slate and rock which is a sample of the material received as coal and paid for as such by one of the largest manufacturing companies in Connecticut. The pieces are so large as to convince one that they were not left accidentally with the coal as it came out of the mines, for the reason that it was not in one or two cars, but many. It causes no end of trouble with the coal crusher, continually breaking gears and pinions, smashing bearings, etc. These breakdowns occurred so frequently that it became necessary to prevent them; this was accomplished, after trying various methods, by installing a set of overload relays. A 20-hp. induction motor is used for each crusher; only about 60 per cent. of the horsepower is required to crush the coal under ordinary conditions; the relays were set about 15 per cent. above the usual required power for the crusher. Cast steel is now used for the crusher gears.

While the average monthly cost per pound of steam for the year 1916 was $0.00027, it has greatly increased until it reached a figure of $0.00042. It would not be fair, of course, to charge this increase to bad coal only because the cost of labor and material has increased.

Sticks, stones, chains—most anything of that nature—in coal will cause serious delays. damage and possible service interruptions in a power plant. Protest by mail to the mine owners, when bought direct, is of no avail. As New England ordinarily gets two-thirds of its coal by water, Fig. 2 is of particular interest, for it shows what comes in with the coal in barges.

The company from which the photograph was received now sends such pictures, without comment, to the mine, and since doing this the foreign substances in the coal have greatly decreased. Try it.

Bonus For Power-Plant Employees

By WARREN B. LEWIS
Consulting Engineer, Providence, R. I.

Bonus paid to power-plant employees does not mean that they must originate saving on which the bonus is based. The author bases the bonus on the saving in power-plant costs per unit output of product manufactured and gives detailed directions for enabling the management to quickly determine by reference to a curve, the bonus due employees.

THE term "bonus" generally means something over and above a fixed compensation or price, based on the net saving effected. It means that if the operator can reduce the cost per unit of product, he should receive a proportion of the savings. It does not mean that he is to originate the methods to be employed. A course of instruction may be, and generally is, necessary, but methods having been established, the employee receives a proportion of the savings effected because he maintains the standard set.

Establishing a Base-Line

In establishing a bonus there must be a starting point, which should be a reasonable efficiency. Call this a base-line. If the plant as a whole has been well operated, then its cost for a period of two or three years might be taken as the base-line. If there have been glaring faults, these should be corrected before the base-line operating costs are established.

The start must be made with the sum total of power-plant expenses, which must bear some definite relation to the product turned out in the plant as a whole. There are few cases where the cost of power (and I refer now to all the items under the general heading of power) does not bear a definite relation to the product manufactured. If the plant is operated at 100 per cent. capacity, the power-plant cost should bear a definite relation to the product in terms of pounds, bushels, yards, tons, etc. If the plant is operating at 50 or 20 or 80 per cent. of its capacity, the cost of power for each will have a relation unlike the others.

It is possible, then, to establish a curve that will show what the power-plant costs per unit of product should be at any given output, and this is the measure most satisfactory, as it includes every factor that enters into power costs. The manager need not worry about boiler or engine efficiencies, uses of steam or economical heating and lighting of buildings, but can group these under the general heading of "Cost per Unit of Product Manufactured," and the weekly or monthly report showing the power-plant costs need be simply divided by the product of the plant to determine whether the set standard is being maintained. He can then compare this cost with those of other plants with which he is familiar or to whose costs he has access.

The first step in establishing a base-line is to divide the power-plant costs into two items—those which bear little or no relation to the volume of product and those more or less proportioned to the volume of product. In every industry there are cost items that are fixed. Some of these are familiar to the accounting department and some are not. The familiar ones are interest, depreciation, taxes, insurance, etc., which are termed "overhead"; but there are others which are as definitely fixed. If the power plant is ready to serve the factory with any amount of power up to its maximum, then the other fixed charges consist of cost of labor, fuel required to bank fires and to keep engines, generators, pumps, etc., turning over but developing no useful power, certain amounts for lubricants, water, ash removal, etc. To a great extent the heating of buildings is an overhead charge against the power plant and is not affected materially whether the plant is running at 25 per cent. or 100 per cent. capacity. In some cases heating may have to be divided into the two elements, but in most cases it is a fixed charge. A certain amount of lighting comes under the head of fixed charges and is not affected by the volume of output.

We have, therefore, to determine, first, what the real fixed charges are on any individual power plant, and one proceeds as follows: Make an appraisal of the plant, determine the value of the land and buildings occupied, of the complete boiler equipment, engines, pumps, heaters, piping, generators, switchboards—everything concerned in the production of power, steam, light and heat, not forgetting the sprinkler systems, lighting systems, etc., which apply wholly to the power plant; also the main lines of pipe running to production centers in the manufacturing buildings, as well as main lines of wires, etc., these being a part of the power plant. Generally, the branch lines and pipes in manufacturing departments are considered as a part of the department and are not concerned in the establishment of power-plant costs. This appraisal having been made, certain charges are entered such as are commonly called overhead; namely, interest, depreciation, taxes, insurance, etc.

Determining Stand-by Losses

The second step is to determine what may be called "fixed costs regardless of output," or *stand-by losses*, in some such manner as follows: If the boilers are maintained at the usual pressure, engines turning over at normal speed, generators excited but delivering no current to the lines, or, in case of mechanical drives, shafting turning but all productive machinery stopped, a certain quantity of coal is being used which may be considered as a fixed cost regardless of production. This includes coal used in banking fires and rebuilding fires which have been cleaned. If one wants to be very accurate, the amount of ash resulting from the burning of this fixed amount of coal is determined, and the cost of removing that ash added.

Next determine what lubricants are used irrespective of production, and certain supplies such as pump and engine packings, boiler gaskets and numerous other things that are not affected by production. Current used for lighting main passageways, the yard, the engine and boiler rooms, etc., is a fixed charge. Coal used on Sundays and hoildays and that used at night is also a fixed charge.

The heating of buildings may in most cases be considered as a fixed factor. In some plants a decrease in the output carries with it the possibility of decreasing the number of departments to be heated; but in most cases the heating will be a fixed item and will not vary generally with the percentage of production of the plant.

Practically all labor employed in the power plant is a fixed item.

A considerable proportion of the total costs is as truly a fixed charge as are the usual overhead items; and the natural result is that if the plant is operating at 50 per cent. capacity, the cost per unit of these fixed charges is twice what it is when the plant is operating at 100 per cent. capacity. It is this that makes the final cost per unit of product not proportional to the volume of product.

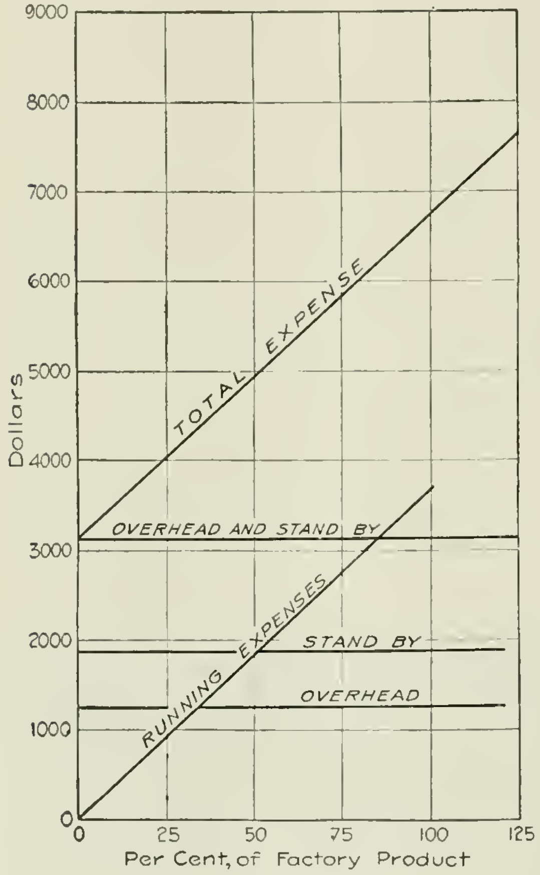

FIG. 1

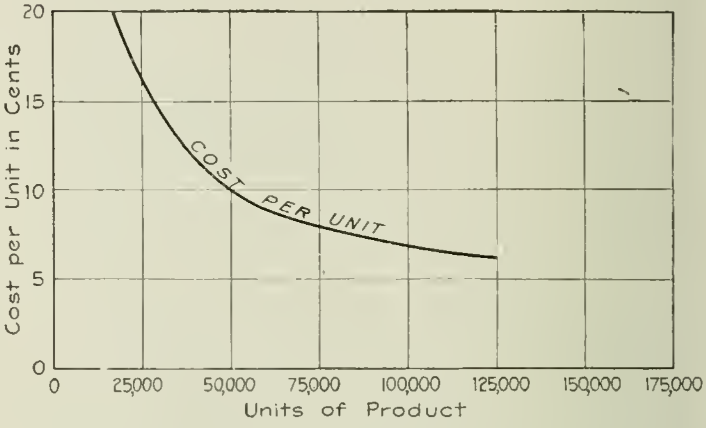

FIG. 2

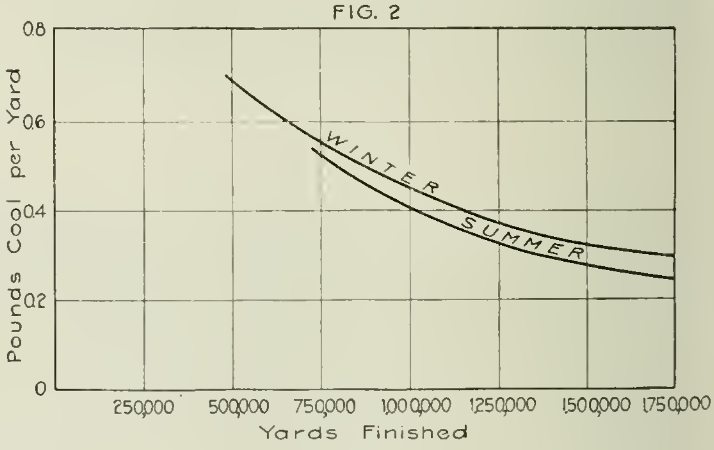

FIG. 3

FIGS. 1 TO 3. CURVES PLOTTED WHEN PLANNING A BONUS SYSTEM

Fig. 1—Expense Chart. Fig. 2—Unit Cost Curve. Fig. 3—Coal Consumption Per Unit of Production.

The third item to determine is the variable costs of the power plant, those which change with the product. As the amount of power required increases, the coal will increase in fairly direct proportion, assuming that the prime movers have a fairly flat water rate. If they do not, it is a simple matter to plot the relation between coal and product as a slight curve rather than as a straight line. If the boiler-feed water is purchased, it will be an item varying with the factory output. A certain part of the ash and a certain percentage of supplies will also be directly affected by the output. We have, therefore, a group of items which increases nearly proportionally to product, and in many instances may be considered as a straight line. If we now combine these two sets of costs, we get a line that shows the actual variation in cost as the productiveness of the plant varies.

To illustrate: Assume a power plant of the simplest character, of 1000 hp., where mechanical power is the only thing required and the equipment is concentrated. The plant is appraised at $100,000; and for the first item we have the overhead, which may be taken at 15 per cent., covering interest, depreciation, insurance and taxes, which is equivalent to $1250 a month. This overhead has no relation to the volume of output and in Fig. 1 is plotted as a straight line.

The next item is the stand-by losses, which are affected by the output. These consist of the following items in dollars per month: Labor, $606; coal, $1170; oil, $37; supplies, $25; repairs, $40; water, $10; total, $1888. The items of supplies and repairs represent the materials used to keep the machinery in good working order, whether it is developing one horsepower or a thousand. The item of $1888 is drawn as a horizontal line because in every respect it is practically the same as overhead. The sum of these two items is plotted as a horizontal line at $3138.

The third item is the expenses which are proportional to product, made up as follows, if the plant is delivering 1000 hp.: Coal, $3510; repairs, $40; water, $100; total, $3650. This is plotted as a diagonal line, with the figure $3650 against 100 per cent. output with proportional amounts against lower outputs; namely, $2737.50 at

75 per cent. output, $1825 at 50 per cent. output, $912.50 at 25 per cent. output, and 00.00 at 0 output. If this diagonal line is now added to the item of overhead plus standby, the total costs are plotted as a diagonal line beginning at the figure $3138 for 0 output and ending with $6788 for 100 per cent. output. If the plant runs a month at 25 per cent. output, the cost would be $4050.50. If it runs a month at 75 per cent. output, the cost would be $5875.50. This chart shows at once the tremendous influence that the stand-by and the overhead have, and how necessary it is to keep them at a minimum. The importance of this is frequently overlooked. In this assumed case they are nearly 50 per cent. of the total maximum cost at 100 per cent. factory output and are more than 60 per cent. of the total cost at 50 per cent. factory output. If we divide the cost for any given week by the productiveness for that week, we establish the power-plant cost per unit of product output.

Fig. 2 illustrates the ratio between product and cost. Instead of using percentages, we may convert this into thousands of units, such as pounds, bushels, yards, etc. Taking the total operating cost at 100 per cent. output of $6788 and considering that 100 per cent. output means 100,000 units, then the cost per unit is 6.788c. At 75 per cent. output, or with 75,000 units, the cost would be 7.83c.; at 50 per cent. output, or 50,000 units, the cost would be 9.9c.; at 25 per cent. output, or 25,000 units, the cost would be 16.2c. per unit. If this chart is kept before the management, it is only necessary to pick out on the curve the proper cost for any given output to determine whether the standard has been maintained. In making such a chart the records of total cost of power should be divided by the output for each period and plotted regularly.

It may take many weeks to check up such a curve. If the factory is operating at about a certain definite percentage of capacity, the opportunity will not be presented to find the actual ratio at some other percentage until the rate of percentage goes up or comes down. In some cases it has taken nearly a year to check up a curve with actual performance; and even then the curve is bound to be a mean between certain extremes.

STAND-BY-LOSSES SHOULD BE WATCHED CAREFULLY

In those industries where steam, hot water and other evidences of power are distributed about the plant, it will be found that the stand-by plus the overhead is a much larger proportion of the whole. In some cases it has been as high as 70 per cent. at 100 per cent. production and a correspondingly larger amount at lower rates of production. This makes it doubly important to watch the stand-by losses even more carefully than the variable running expense. If the industry is such that the influence of the out-of-doors temperature is considerable, then two curves should be established, one for summer and one for winter conditions, the transition from one to the other being more or less arbitrary and depending somewhat upon the climate.

Fig. 3 illustrates two curves that actually apply to an industry where large quantities of steam and water are used and the cost of heating water in winter is much greater than in summer. In this plant the bonus is figured on the coal consumption alone. The curve shows the ratio between production and pounds of coal per unit of production, and well illustrates the rising cost of coal per unit when the factory output is increased. It is evident that it is quite impossible to judge fairly from a week's operation. It is almost impossible in many industries to get the actual product for one week. Materials may be put into process which do not reach the packing room for several weeks, and more goods may be shipped than are in actual process in any given week. It is therefore necessary to figure costs over a longer period, say four weeks, or by calendar months; and at the same time determine with a fair degree of accuracy what is the actual output of finished product.

The curve, then, becomes the basis of a bonus system of payment. Some engineers have argued that it is not a fair one, that all that the operating engineer can do is to make steam efficiently, run his engines, pumps, heaters, etc., as well as he knows how, and that he has no control of the situation beyond his department. That is partly true and partly not true. The functions of the chief engineer should extend beyond the confines of the engine and boiler rooms. He should spend at least one-third of his time around the plant, and he should have an inspector going around the plant continually watching out for improper use of power, light, steam, etc. The chief engineer should be directly concerned in seeing that the process machinery is maintained in an efficient condition. This is particularly true with regard to apparatus that uses steam in any form. If we include in the power plant all the equipment which in any way affects the use of fuel, it becomes a comparatively simple matter to place upon the chief engineer the responsibility for the efficiency of the entire power-making and power-using equipment, and for its cost per unit of production.

SPECIFIC APPLICATION TO BLEACHERY PLANT

An instance of the specific application of the theory herein advanced is that of a cotton-cloth bleachery and finishing plant. Here the measure was the number of yards of cloth finished in a given period, and it was found that an average of the number of yards put into process and of the yards shipped could be taken as the basis of production. Distributed over a period of four weeks the inaccuracy due to the possible holding up of goods in the plant was shown to be more or less reduced. From records extending over a period of two or three years it was found that for any given production the amount of coal burned did not vary much notwithstanding a great variety of processes carried on and continually changing methods of handling goods. This was accounted for largely by the fact that the fixed operating costs, as before explained, were a large part of the whole. The ratio between the coal burned and the yards finished was not a constant one by any means, but varied with the volume of the product, so that a curve could be produced which would show the actual ratio under any given conditions. This curve was based on costs as they had been for a considerable period of time. The employees of the power plant were offered a certain percentage of any saving they could effect. The chief engineer did not accept the offer with any interest, explaining that he did not believe that a material saving could be made. The company employed a consulting engineer to study the conditions in the power plant, with the result that with the coöperation of a new engineer the costs were greatly reduced and the employees received substantial rewards. The saving came not only through the better operation of the machinery, but through the reduction in the use of steam all over the plant.

Two factors must be recognized, one of which has been already mentioned—that of proper advisory service and a process of education. By far the most important is the attitude of the management toward the whole plan. There must, first of all, be a keen desire to reward the power-plant force for their efforts and a genuine feeling that a man's earnings should be based on what he saves his employer rather than on what some other man gets. Because $30 a week is a recognized standard for a certain class of help is no reason why a man should not get $10 a week additional if his employer can make $10 or $20 or $30 a week additional out of the man's effort. The bonus paid the first year will come from the actual reduction in costs of operation. The bonus paid after that will be due, not so much to still further reducing costs, as to keeping them down to a minimum; and it is certainly worth as much to keep the costs down as to bring them down in the first place.

Work of the Massachusetts Boiler Inspection Department

In the accompanying Tables II and III, are given the chief items of interest in the work of the Boiler Inspection Department of the State of Massachusetts since preliminary investigations by Thomas Hawley, of Boston, in 1893 and 1894 up to 1917. The tables should be of considerable interest to all those interested in boiler legislation, construction and operation.

The total number of Massachusetts standard boilers and air tanks constructed, received into the state and reported during the last five years, are given in Table I.

The following insurance companies are authorized to insure and inspect boilers in the Commonwealth: Employers Liability Assurance Corp.; Fidelity and Casualty Co.; Hartford Steam Boiler Inspection and Insurance Co.; Maryland Casualty Co., Mutual Boiler Insurance Co., Royal Indemnity Co.; and Travelers Indemnity Co. The 148 insurance inspectors, certified by the state, inspected 19,607 boilers and 376 air tanks in 1917.

It is interesting to note some of the violations of the various laws enforced by the boiler inspection department during the last year: assaulting an officer, 1; causing a boiler to be operated by person not properly licensed, 2; causing boiler to be operated without necessary safety appliances, 1; operating boiler without certificate of inspection, 4; failure to pay boiler inspection fee, 3; operating steam plant without proper license, 5; operating electric derrick without license, 1. It is seen that violations are few.

When the German steamship, the "Kronprinzessin Cecile" was interned in Boston, members of the department took charge of the mechanical equipment aboard. Since the outbreak of the war three members have entered service under the flag.

TABLE I. BOILERS AND AIR TANKS INSTALLED DURING LAST FIVE YEARS

The Forcible Shutting Down of Isolated Power Plants

BY PERCIVAL R. MOSES

A complete account of the various events which led up to the hearings now being held before the Public Service Commission for the First District of New York, to determine the advisability of shutting down isolated plants and substituting central-station service, in order to save coal.

THE Public Service Commission is holding a series of hearings which are technically directed to the question of the rates for breakdown and auxiliary electric service and which are largely an investigation of the possibility of establishing an off-peak rate for electricity which shall induce owners and operators of private power plants to shut down such plants when the use of fuel in them is greater than it would be if the electricity were derived from the New York Edison Co. or some other public utility.

The history of the case is as follows: In November of last year, when the threat of fuel scarcity became imminent, I wrote the Fuel Administration in Washington, suggesting that a great measure of fuel conservation would be obtained if coöperation between public utilities and the owners of private or isolated power plants could be enforced. This letter, which clearly outlines my position, is as follows:

366 5th Ave., New York City, Nov. 9, 1917.

United States Fuel Administration,
Washington, D. C.

Dear Sirs: I have written you before, suggesting that a very large amount of fuel could be saved by enforcing coöperation between the public utilities and the owners of private, or isolated, power plants. I have not heard from you further in the matter, and I assume that the immense amount of work you have had to do prevented a careful consideration of the matter, because there can be no possible dispute as to the facts. What I want to see accomplished is the supply by the public utility of all electricity which it can most efficiently supply, and the supply by the private power plant of all the electricity it can most efficiently supply.

That there are distinct fields for each type of plant is evident on the slightest consideration of the subject. A large building needs coal to heat it. The heating is accomplished by steam at low pressure. By adding 3 or 4 per cent. to the amount of heat in the steam, the steam can first be made to drive engines and dynamos making electricity and afterward be used for the heating. In this way all the energy delivered by the coal to the steam is utilized, whereas in the public-utility plant of the best type not over 15 per cent. is utilized. On the other hand, during certain periods of the year and certain periods of the day and night the more efficient plants of the public-utility company should be utilized and the engines of the private plant should be shut down, as such engines are, of course, inefficient except when their exhaust steam can be utilized.

I have estimated that 100,000 tons of coal a year could be saved in New York City alone by carrying out this coöperation to a reasonable extent. A practical example will show that this idea is not a theoretical one. The Columbia Trust Co. owns a building at 60 Broadway, about 20 stories high, 60 x 150-ft. plot. Electricity was purchased one year in the winter and the next year it was generated in the building. The same kind of coal was used under the same conditions of firing. Less coal was used during the months of December, January, February and March in the year when the electricity was being generated than was used in the same period when electricity was being purchased. Approximately 150,000 kw.-hr. of electricity was generated during the period, and this would have required of the Edison company, allowing for wastes and distribution, over 200 tons of coal, so that by this change in one building a saving to the community of 200 tons of coal was effected.

This same condition has been shown to exist in a number of other instances where a number of tests have been made with and without electric generating plants. For example, we made a test for the Mutual Insurance Co., Richmond, Va.—24 hours with their own plant and 24 hours with purchased electricity, running their own steam plant, during the winter season—and the results were the same as I have mentioned at the Columbia Trust Co.; that is, less coal was used when the plant was running than when the plant was not running. On the other hand, it is a well-known fact that the engines used in private plants are far less efficient than the turbines of the big central stations, so that in the summer months the use of coal by the private power plant for a given quantity of electric current must be more than in the central station, so that from the point of view of the community it would pay during the summer months to have the electricity generated at the central-station plant. This coöperation could be easily obtained by a system of rates for electric current which would make it economical for a private-plant owner to use electric current during the summer and other light-load periods. The advantage to the public utility must be obvious, as an additional load would be obtained which would involve practically no additional investment.

This letter received a prompt reply from the United States Fuel Administration, referring it to O. P. Hood, chief mechanical engineer of the Department of the Interior, who was working for the Fuel Administration. Mr. Hood requested a more detailed statement of my suggestion, which I sent him within a few days. This was acknowledged on Dec. 6, stating that the matter had been referred to another and that the desirability of coöperation was not questioned, but that the difficulty appeared to be that of getting a definite knowledge of conditions.

In another letter of Dec. 26, Mr. Hood said that it seemed to be better to bring the matter to the attention of the local fuel administrators, and this was done by me in a letter of Jan. 2, to Mr. Wiggin and Mr. Schley, state and county administrators, to whom I submitted a brief plan, as follows:

OUTLINE OF PLAN OF COÖPERATION

Hundreds of thousands of tons of fuel could be saved if through coöperation between the public-utility plant and the private power plant each of these could be operated to its utmost efficiency. While this cannot be entirely realized, there is a very simple plan by which it can be realized in large measure.

First, private plants should be shut down during the summer months and during the balance of the year with the exception of the very cold winter weather during the so-called "off-peak" period, which in the vicinity of New York is from 10 p.m. to 6 a.m. That is, I would advocate the shutting down of private plants except those which are utilizing their exhaust steam for manufacturing purposes during the nonheating season—May, June, July, August, September and October—and during the other months, with the exception of December, January, February and March, from 10 p.m. to 6 a.m., with the possible exception of hotel plants, as in these plants exhaust steam is largely used for heating water and for drying purposes; hence, high efficiency is obtained.

These plants may be shut down without hardship to the owners provided a rate is made by the public-utility company which would not exceed 2c. per kw.-hr. for moderate consumers—that is, consumers up to 1,000,000 kw.-hr. per year—and possibly 1½c. per kw.-hr. to consumers of larger quantities.

The public-utility company can easily afford to make such a rate because the current it would supply during these periods would be off-peak current, which could be furnished without any increase in investment in plant or in underground mains or in real estate; hence, the only increases to which the public utility would be subject would be increases in operating expenses and the small cost of connections from the underground mains to the buildings. In most cases it will be found that connections are already in, so that in reality the only increase to the public utility would be the increase in operating expense. This will be found to be less than one cent per kilowatt-hour.

Second, private power plants should be encouraged to develop their market for steam and electricity in their immediate neighborhood during the heating season up to the extent of their present capacity, as in this way the most perfect utilization of fuel and labor can be obtained.

Reasons for the Suggested Changes

The reason why these changes should be made is that in the winter months when the private power plant is operating, supplying electricity and steam for heating, almost perfect utilization of the heat contained in the steam is obtained, as the steam is first used at high pressure to generate power and electricity, and then afterward as exhaust steam is used for heating purposes. During this same period the public utility is generating steam at high pressure and is wasting a large part of the latent heat in the exhaust steam because it has no place to use it.

On the other hand, during the summer months in such plants as cannot use their exhaust steam for drying or manufacturing purposes or for heating water, the private plant wastes 95 per cent. of the heat contained in the steam, whereas the central plant on account of its high efficiency equipment and condensers wastes only 85 per cent.

In so far as the off-peak load is concerned, the public utility would benefit because it would obtain a load which would bring its average load up to a more efficient point; that is, the private-plant load would help fill in the valleys of the public-utility load, or as it is usually expressed, the load factor would be bettered.

Shutting down private plants during the off-peak period would shut them down when they are least efficient, in the use of both fuel and labor. I have known cases where the coal per kilowatt-hour ran to 30 lb. during these light-load periods, and 20 lb. is quite common. It results, therefore, that if a plan such as that just outlined should be adopted, instead of obtaining from 200 to 250 kw.-hr. per ton of coal burned, there would be obtained from 700 to 800 kilowatt-hours.

The danger of making suggestions to bankers and others with but little knowledge of engineering matters was demonstrated strikingly by the circular sent out by Albert H. Wiggin, state fuel administrator, on Jan. 14, 1918, urging owners of private power plants having breakdown-service connections to utilize to the fullest extent their connection with the Edison company, and on Jan. 15 I wrote to Mr. Wiggin pointing out the error of his suggestion and that instead of fuel being conserved by obtaining electricity from a central source in winter months fuel would be wasted.

Many of these letters were sent to the Public Service Commission of the First District with the request that they start a series of hearings looking to the establishment of an off-peak and summer rate for current and urging the necessity of quick action so that an equitable rate might be made and the new methods go into effect at the close of the heating season.

These hearings started on Feb. 25, and so far the commission has simply asked the public-utility officials to state their side of the case, which they have done at great length with practically no cross-examination.

Mr. Wiggin's letter and other indications apprised me of the fact that influence was apparently being brought to bear to take advantage of the country's necessity in an attempt to shut down private power plants generally, winter and summer, regardless of the fact that during the winter months and during such other periods of the year when exhaust steam can be fully utilized the private power plant is the most efficient means of production.

A circular letter was therefore addressed by me to a great number of owners of private power plants, calling attention to this condition, and a number have agreed to join with me in properly presenting the facts as we see them and as I have outlined them already to the Fuel Administration.

Benefits To Be Derived by Use of Plan

My position in the matter is that if the plan as outlined is carried out, the public utility will benefit by obtaining a large additional amount of profitable business at a minimum of cost. The country will benefit because the minimum amount of coal will be used for the generation of electricity. The private-plant owner will benefit because he will obtain the electricity used by him during summer and off-peak periods at not more than his present cost and he will be relieved of the necessity of operating the private plant.

I estimate that the saving in fuel in New York City alone if the plan outlined was carried out in full would be in excess of 200,000 tons per year, and if the plan was extended throughout the country the conservation of fuel would mount up certainly over a million tons per year. In addition to this a certain amount of labor would be released for other service, and this under the present conditions is equally important.

The facts as I have presented them seem to be indisputable. The plan presented is practical, and it is merely an attempt to apply a correct economic solution to the problem of the supply of light, heat and power. It is presented neither on behalf of the owner of the private power plant nor on behalf of the public-utility company, and for the reason that it is not an ex parte proposal it should be considered on its merits

Editorials

Investing in Liberty

JUST what is this thing called liberty in which and for which we are asked to invest billions? For the individual liberty is simply the ability to react to impulse, to the impulse of hunger or thirst, of self-defense or self-preservation, as well as to those higher impulses of self-determination with which we usually associate the word. With a complete lack of liberty life would cease. It is as necessary to life as air and light and water and food—in fact, more necessary, since in the last analysis it means access to these things. And up to a certain point, as in the case of all these things, the less liberty the less vitality. One may exist on a little liberty, as on a little air or a little food, but one cannot support normal life on it unless it is abundant.

But there is such a thing, also, as too much liberty, as of all the other necessities of life. And furthermore, it is not a thing whose supply is inexhaustible. Like air or light or water, it can be so restricted by monopoly that untold suffering and death result to those whose access to it is cut off. Look at Belgium or Germany itself.

The Prussian Junker would hardly consider as liberty the restrictions which we in this country impose upon our conduct. He would miss here that superabundant liberty to which he has become accustomed in the land of the Kaiser—to saber civilians who make faces at him, to elbow women off the sidewalk, to radiate arrogance with impunity. He would scoff at our sensitiveness to the rights and feelings of our neighbors, at our habit of chivalry and of kindness and compassion toward those weaker or more helpless than ourselves. This thing which we call liberty in America, this everyday conduct hedged about by law and conscience and the dictates of humanity, to the German Junker seems a mockery of the word. But by liberty he means a monopoly of liberty, and we, its proper distribution.

It is to secure and preserve for every inhabitant of the United States his share of liberty, that greatest of life's necessities, that we have declared war against the Hun Monopolist, that we are sending hundreds of thousands of our boys to the firing line in France, that we have bought billions in Liberty Bonds, and are now to begin the third loan campaign on April 6, to multiply that great investment. It is worth every cent of the mighty effort and much more. Would you fight for a water hole after a day's ride across the desert? And if you could not fight, would you give your all for access to that elixir of life without which you must go mad or die? Then fight for liberty; it is equally precious. And if you can't fight, give—give your all, or, rather, in this case, lend it at a good rate of interest. For, happily, your forefathers have so fortified your position in this world that you are bound to receive your contribution back with interest.

It is impossible to pay too much for, to invest too much in, liberty. The need is great that every man, woman and child in this country put everything he is and has into this vital struggle, once for all to smash the would-be monopolist and all his breed. We have floated two mighty loans already, now comes the third. As our artist has depicted in the colored supplement to this issue, the Kaiser is tottering on his pedestal. Therefore, again with Uncle Sam, *one, two, THREE, NOW, ALL TOGETHER!*

Inefficiency in Refrigerating Plants

IN last week's issue of *Power* an interesting paper on the economy of refrigerating plants was presented Apparently, conditions in this field are far from ideal, as the author ventures the opinion that "of all power plants the refrigerating plant is most wasteful." By and large this statement is probably true, and as to the reasons, there are several having an important bearing. Although the refrigerating cycle is not particularly difficult to understand, as it is practically the reverse of the condensing steam plant, there are many factors entering into the ultimate economy. This multiplicity of factors, each a source of possible waste, and the proper correlation of the various elements of the refrigerating and steam plants, make economical results more difficult to obtain. Further reasons are a decided scarcity of good refrigerating engineers and general inability on the part of the management to realize the possibilities of the plant.

As expressed by the author of the paper, there is a wonderful future in the refrigerating field, but before any great headway can be made, men must be developed, who can safely and economically operate the plants. The management must be educated as to what results might reasonably be expected and be made to realize the importance of proper selection, promotion, competition, training and salary based upon results. This in itself is a big task, worthy of the efforts of the various refrigerating and ice-making associations.

With plant examination and supervision where it is needed by well-posted refrigerating engineers, progress may be expected. This, of course, entails constant touch with the operating force by means of complete records and the checking of results from day to day. Inefficiencies will immediately show and may be corrected. From a study of existing conditions and the operating data, characteristic curves for each plant may be prepared. These curves should cover all factors relating to economy and should be used as a guide and basis of comparison for future operation.

Briefly, the engineer is the big factor in the problem. He may be educated as suggested in the previous paragraph, but until the management realizes the need of competent men and the necessity of salaries commensurate with their engineering knowledge, it is quite probable that the refrigerating plant will continue as a model of inefficiency.

Bonus for Power-Plant Employees

ON OTHER pages of this issue appears an article on "Bonuses for Power-Plant Employees," by Warren B. Lewis, a consulting engineer well known in New England and particularly familiar with mill power-plant practice in that section of the country noted for its industrial activity. The impressive feature of the article is its scope; the author embraces all power-plant employees as those who should share in the bonus. This, while unquestionably most equitable, is uncommon. Usually, bonuses are paid only to boiler-room crews on the assumption that they have greatest influence over the source of heaviest loss. Where a plant is large, and especially if it is one supplying heat and power, as to a bleachery or other large consumer of steam for industrial purposes, it certainly is best for the management to provide a bonus system wherein all power-plant employees will share in the savings effected.

Mr. Lewis says that because the employee (and he means everyone in the plant from the chief engineer down) shares in the bonus "does not mean that he is to originate the methods [of saving] to be employed." When considering the application of a bonus system to power plants, managers are too likely to predicate consideration on the premise that the employee should originate the means of saving. That is too often taken for granted. As saving, to the management as well as to the employees, is the prime object of paying a bonus, it is obvious that the method that gives the greatest return is worth while whether it comes through the management's own staff or after survey of the plant by a consulting engineer.

It is of interest that the system of paying bonuses, as told of by Mr. Lewis, presupposes that the management "include in the power plant all the equipment which in any way affects the use of fuel," and that when this is done "it becomes a comparatively simple matter to place upon the chief engineer the responsibility for the efficiency of the entire power-making and power-using equipment, and for its cost per unit of production." Needless to say, this assumes that the chief engineer be a high-grade man, one who is capable of meeting and discussing problems with department heads, who has a good working knowledge of relative values, of cost accounting and apportionment of charges—these along with a most thorough knowledge and understanding of his plant and of the availability of equipment, materials and supplies which the market affords. Even though the company retains a consulting engineer, these qualities in the chief engineer in charge are highly desirable.

Mr. Lewis is aware that many will criticize his accounting of power-plant performance on the unit of product of the works or mill turned out per unit of power-plant cost. But he meets the probable criticism very well, we think.

When Contracts Go Begging

During these days when everybody is talking in millions and even billions of dollars, the fellow with a few paltry thousands of dollars does not cut much of a financial figure, if the *Mining Journal*, of Marquette, Mich., is correct in the publication of an article relative to the placing of an order amounting to forty-five thousand dollars for new equipment. It reads as follows:

> The superintendent of the light and power department and the department's engineer have gone a-journeying to see if they can find anyone who will condescend to consider the small matter of an order for forty-five thousand dollars of electrical and hydraulic machinery. They have gone because their tentative inquiries among manufacturers brought, in most instances, no response at all, and in others only a languid interest. In normal times the announcement that Marquette was seeking to place an order for forty-fiv thousand dollars of machinery would have meant an eager charge on the city officials, by most resolute agents, and another besieging of the city hall during the period of consideration of the proffers, such as has frequently been seen in the past. But these are not normal times; they are war times. An individual, or city, that ventures to raise a voice about a mere matter of forty-five thousand dollars of machinery finds that he raises it in vain. The magic word "million," at least, has to be used to secure a hearing.

The foregoing is doubtless true at present, but there is coming a time when a forty-five thousand dollar contract for power-plant apparatus will look as good as a full coal bin did this winter.

The Alien Employee and the Labor Turnover

ONE of the most perplexing problems in industrial plants at the present time is that of the many millions of aliens now employed. This is a matter calling for careful and delicate handling, and it would be helpful to large employers generally to know what others are doing to solve this problem. The columns of *Power* are open to a discussion of this subject.

The excessive cost of labor turnover resulting from unsettled war conditions is another matter that is causing the employer considerable anxiety. Many plants find that costs run from ten to one hundred dollars for each employee broken in and that the annual total is enormous. What methods have you adopted to reduce this cost and what results are you getting? Give others the benefit of your experience through the columns of this paper.

The McGraw-Hill Company, Inc., publishes ten papers. Each of these papers has its own half dozen, more or less, distinctly separate departments, such as advertising, editorial, subscription, circulation, makeup, with one centralized mail department for all. It would considerably facilitate matters for those charged with expeditiously distributing to the proper persons or departments the hundreds of letters that come in daily, if our correspondents would remember to mention, when they know it, the name of the paper for which their communications are intended, as well as the department connected with it. Thus, for instance, matter addressed to Editor of *Power*, Advertising Manager, Subscription Department, etc., will be dispatched more quickly and have more prompt attention than that addressed merely to the McGraw-Hill Co., which has to be read through, very often passed through many departments and hands, previous correspondence, if any, looked up, and a great deal of valuable time and energy wasted that might otherwise be spared, in an effort to get it to the proper person to be efficiently and satisfactorily taken care of.

Correspondence

Removing Drill Chips by Vacuum

The following is a useful kink when drilling holes, reseating valves or similar work where it is difficult to remove the chips. On the nozzle of an ordinary molder's hand bellows solder a reducer of the size and shape desired and close up the regular air-inlet valves in the bellows. To operate, close the bellows, place the nozzle near the chips to be got rid of and open the bellows quickly. The rush of air will carry the chips into the bellows, after which they can be easily blown out again. **W. H. Bennett.**

BELLOWS FOR VACUUM

A Wooden Tank Repaired

It does not seem that the wooden tank repaired as described on page 164 in the issue of Jan. 29, 1918, could be considered safe to have over one's head. Atmospheric moisture and minute seepage will collect between the cement coating and the wood, and it will not be long before the planks, weakened by decay, will give way under the load.

"Safety first" would surely require a new tank.

Lynn, Mass. **P. P. Fenaux.**

[The repair job referred to, when finished, would appear to be a concrete tank reinforced by the original planking banded with iron hoops. No doubt a time will come when the wood will have become decayed to such an extent as to afford no support or backing between the bands and the concrete, but this does not seem to be its present condition.—Editor.]

Care of Electrical Equipment in Cold Weather

A few words may be in order concerning the care of electrical apparatus, particularly motors and generators which are exposed during cold weather.

It is very easy for machines to get "wet" during cold weather, even though not exposed directly to rain or snow. Condensation is at the root of the trouble. If a cold machine is brought into a warm room, the atmospheric moisture condenses on the machine's cold surfaces, just as it does upon one's spectacles under similar conditions. It is possible for a great deal of moisture to be formed and absorbed by an electrical machine in this way. It may also happen that condensation will occur while a machine remains out of doors covered and unmolested, a sudden change from low to higher temperature being responsible. This is particularly liable to occur with large machines, the internal temperatures of which change but slowly.

The preventive of trouble lies in removing the cause. Store machines in a warm place if possible and do not move them from a cold into a warm place suddenly, but bring about the change gradually. If a machine is stored outside, protect it well and provide resistors or other means to keep it moderately warm, particularly whenever a change from cold to warm weather is expected.

When a piece of electrical equipment has absorbed moisture, it should be dried out before use. The methods for doing this are quite familiar (see *Power*, p. 46, Jan. 8, 1918). The drying should be continued until insulation resistance, as measured by a megger or other means, indicates that the machine is in good condition again and safe for use. **Gordon Fox.**

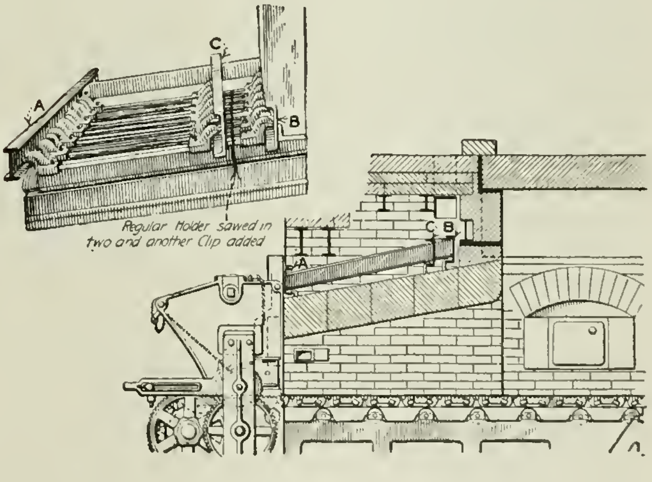
Holding Up the Curtain Wall of a Stoker

The illustration shows my way of holding the curtain wall of a Green chain stoker in place, independently of the arch. The old way was to use the channels marked *A* and *B* to hold the T-bars (suspended under them) on which the arch brick are hung and upon which the curtain wall is built. But when the arch burns out, down comes the curtain wall also. By adding another channel, marked *C* in the illustration, and cutting the T-bars and adding another clip, then bolting a 6-in. angle iron on the back of *B* so as to support the curtain wall independently of the regular support, the curtain wall will always be held in place and the arch can be replaced without disturbing it. **J. J. Neville.**

Chicago, Ill.

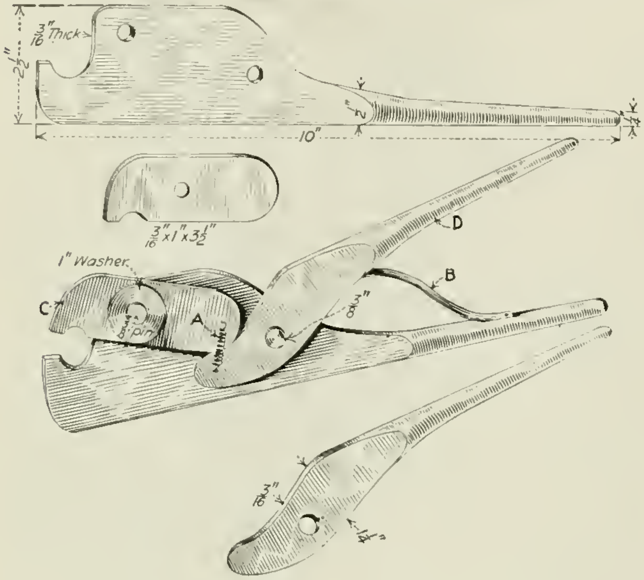


CHANGE IN SUPPORT FOR ARCH AND CURTAIN WALL

Cutter for Large-Sized Wire

Cutting iron wire or large copper conductors is impractical with shears and impossible with ordinary cutting pliers. A powerful and very compact cutter, which anyone can make in his spare time, is shown in the figure. This tool is made of $\frac{3}{16}$-in. steel, hardened on the cutting edges, and will cut copper wire up to $\frac{7}{16}$ in. diameter, or even larger if the handles are made longer than those shown. The spring *A* holds the cutter *C* against the lever handle *D*, while the spring *B* holds the handles apart. M. P. BERTRANDE.

Ozone Park, N. Y.



PARTS AND ASSEMBLY OF WIRE CUTTER

Combustion in Boiler Breechings

As considerable interest seems to be centered on the subject of combustion in the fuel bed of hand-fire furnaces and in the gas-producer action of fuel beds, and with explosions in boiler furnaces, I am telling the following points from experience in our boiler room.

When the writer took charge, two of the boilers were fitted with ordinary stationary flat herringbone grates and natural draft and two were fitted with a forced-draft system employing hollow grate bars through which the air was blown, the bars having narrow slots on the upper surface through which the air reached the fire. The breeching over the latter boilers was badly warped and showed plain signs of overheating.

It was soon found that when heavy loads were being carried, a gas flame was present in the breeching after every firing, gradually dying out as the fires burned clear. The coal used was of high volatile content and southern Illinois origin. The boilers were of the Heine type, and the baffling was in good condition, so that there was no question of the fire going directly through the tubes to the breeching. The firemen reported also that the furnaces would occasionally "puff" badly, especially if a door were opened wide a short time after firing.

The breeching not infrequently became red-hot, and because of the warping it did not make tight connections on top of the boilers. It soon became evident that the combustion of the gas was supported by the air drawn in at these openings. It was also found that the flame did not occur if the furnace doors were left open about an inch for a minute or two after firing. If the flame was permitted to start by keeping the doors closed, it could be extinguished at once by slightly opening them. This showed that the trouble was caused by insufficient air in the furnace. As long as we had the forced-draft grates, we kept the doors open a little for a minute or so after each firing.

The air forced into the furnace from the grates at high velocity made a very hot fire close to the grate, but it was not sufficient for complete combustion, and the fuel bed acted like a shallow gas producer. The flame in the breeching was caused by the burning of the producer gas so generated, enriched by the gases distilled from the green coal just after firing.

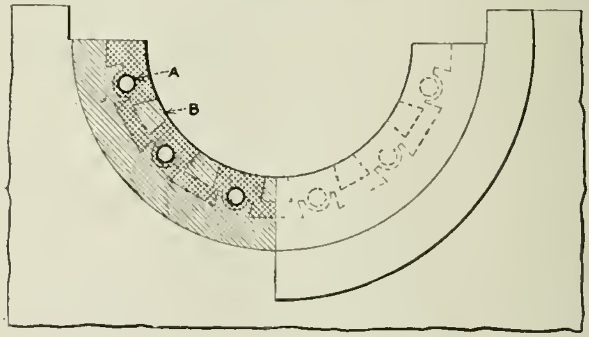
I believe that this condition is likely to occur in other hand-fired forced-draft plants and that it would be well for operators of such plants to be on the lookout for trouble in this direction. C. H. SONNTAG.

Cape Girardeau, Mo.

Hot Gas-Engine-Bearing Remedy

On a 1200-kw. gas engine direct-connected to a generator, the main bearings ran hot although they were water-cooled by means of a series of brass pipes shown at *A* in the figure. The pipes were connected by return bends and embedded in the babbitt metal.

We tried different mixtures of babbitt in the bearing and various pressures on the cooling water, but these did not remedy the trouble, the worst part of which was that the babbitt wore down quickly, throwing the generator's armature out of the polar center, consequently changing the magnetic pull between the field poles and the armature. We finally made a series of soft-bronze grids, or strips *B*, and poured the babbitt around them as shown. The bearings, where necessary, were scraped to a good fit. Since making this improvement, no trouble has been experienced. These strips help the babbitt to stand up under the heavy pressures, and the babbitt particles embedding themselves in the bronze faces form an excellent lubricant.



SECTION THROUGH GAS-ENGINE BEARING SHOWING LOCATION OF BRONZE STRIPS

I would like to hear an expression of opinion from *Power* readers on why the bronze strips are so effective in remedying the trouble. I believe that mixed-metal bearings have proved very satisfactory where used.

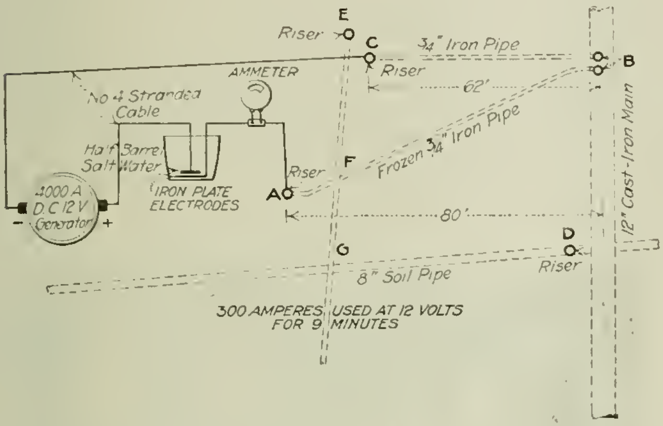
Chicago, Ill. C. A. MERTON.

Thawing Frozen Water Pipes by Electricity

During periods of extremely cold weather the frost penetrates deeper into the earth than usual and frequently freezes embedded water pipes that are ordinarily considered as being below the frost line or pipes which under normal cold-weather conditions would be protected by means of wrappings, conduit, etc. In and around the plant it is generally easy to get enough heat to thaw a frozen pipe, but the first problem is to get into contact with the pipes in order to concentrate the heat so as to make it effective.

It is no easy job to dig down through two or three feet of frozen earth or tear out insulating coverings to get at piping; in fact, by far the greater amount of time and labor is employed in getting at the pipes so that the actual thawing may be done.

For such cases as the foregoing, the electrical method of thawing saves all this unnecessary labor. Many power-plant engineers are aware that pipes are being successfully thawed by electricity, and while they have knowledge of its being done in the cities by lighting and power companies, it is associated in their minds with special apparatus and transformers and with the belief that alternating current is necessary.



LAYOUT OF PIPING AND THAWING EQUIPMENT

It is preferable to use alternating current for this work, because greater amperage can be obtained from commercial circuits by means of a step-down transformer. The use of the transformer in the electrical system charging the pipe line also insulates the high-voltage circuit from the low-voltage, thereby reducing the danger of shock and grounds with gas piping, etc. However, direct current can well be used because it is the heating effect only that is required.

The necessary equipment to use a direct-current circuit for thawing water pipes consists of a water rheostat, which may be a barrel of salt water with two electrodes made of pieces of iron plate or other metal and a length of stranded cable sufficiently heavy to conduct the current used without excessive loss. An ammeter is also desirable, since too great a current may damage the piping.

Data on the number of amperes and the time required is likely to be misleading, for the reason that all the current may not traverse the pipe being thawed as there is liable to be current leakage through the damp earth to other piping. For instance, in a particular case in which an electroplating generator was used to supply 300 amperes at 12 volts, it was estimated that 50 amperes was bypassed, therefore only 250 amperes was used effectively. The apparatus used consisted of a water rheostat made from a half-barrel filled with salt water, two 9 x 12-in. iron plates for electrodes, about 75 ft. of No. 4 stranded wire and an ammeter. The entire length of the circuit was about 230 ft., and the time to produce running water was 9 minutes.

The figure explains the conditions of the case in question. Pipes *AB* and *CB* were tapped directly into the 12-in. main. The vertical distance between any two pipes was small and all were from two to three feet below the surface. At *C* the ¾-in. riser terminates in a sink without sewer connections. The pipes were not disconnected from the risers for the reason that all were short runs. *A* terminated at a humidifier on the second floor of the building and was practically insulated from the earth, thereby presenting an isolated condition. This was also true of riser *D*, which terminated in a watering trough. The water rheostat was short-circuited when the current was in use.

Meter readings taken from *A* to *D* and *D* to *B* showed that there was considerable current leakage, and it was estimated that about 50 amperes was diverted by way of *F*, *G*, *D* and *B*. However, in this case the freezing was between points *A* and *F*, therefore the leakage was of no consequence. The following figures were obtained in connection with an alternating-current portable pipe-thawing outfit operated by a central-station company. The primary of the transformer was connected to their distributing line and the 110-volt secondary to the pipes to be thawed on the premises.

Size of Iron Pipe, Inches	Length	Amperes	Volts	Time in Minutes
¾	60	350	110	20
¾	70	300	110	30
¾	100	150	55	12
1	250	480	50	15

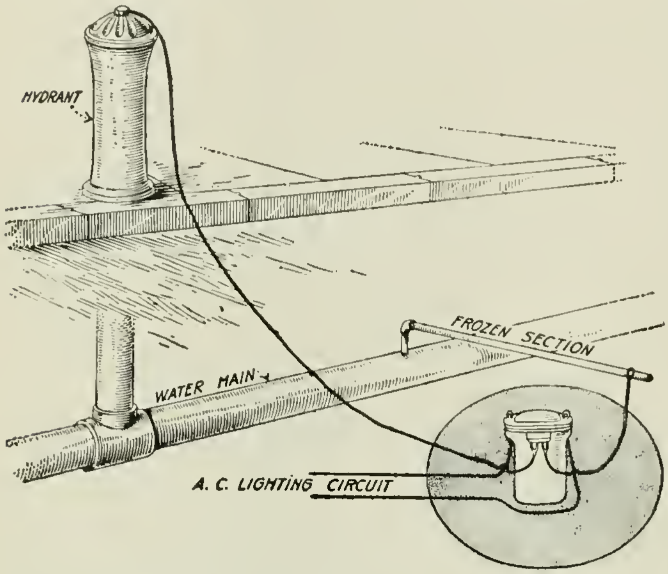
The writer has also used a 200-ampere-hour 12-volt storage battery for thawing water pipes with satisfactory results. MATHEW KING.

Passaic, N. J.

It is quite generally known that a heavy current of electricity passing through a frozen water pipe will heat it sufficiently to melt the ice. It is not, however, so generally known that enough current can be taken from an ordinary lamp socket to accomplish this result provided the circuit is an alternating-current one and a small transformer is available.

The writer recently thawed out a ¾-in. service pipe, which was frozen solid for a distance of about 25 ft., with a 5-ampere current at 110 volts, taken from a house circuit. The current was passed through a 500-watt transformer having a 1 to 12 ratio, thus delivering at the secondary a current of approximately 60 amperes. The secondary wires were connected directly to the frozen pipe line and hydrant, as shown in the figure so as to include the frozen section between the connections. No resistance was necessary on account of the low voltage of the current. The current was left on for nearly two hours before water came, but the time required was longer than it otherwise would have been on account of it being necessary to make one connection to a hydrant 150 ft. away from the frozen pipe, as a connection with the frozen section could not be had in less distance without digging in the ground. This, no doubt, caused considerable leak of current through the ground that otherwise would have passed through the frozen pipe.

Any small transformer having a capacity of 500 watts or more will do the trick. An ordinary sign-lighting transformer of 500- or 750-watt capacity is convenient, and is also useful for other purposes, and the cost is only slightly more than an electric-light company charges for one thawing job.



TRANSFORMER CONNECTION FOR THAWING FROZEN SECTION OF WATER PIPE

These transformers are foolproof, and there is not the slightest danger in using them. They can be short-circuited on the secondary side without injury. They take current from a lighting socket on the primary side at 110 volts at about 5 to 8 amperes, and deliver current on the secondary terminals at 10 volts and from 50 to 75 amperes. They may also be obtained for use on a 220-volt circuit. A 10-ampere fuse should be used in the circuit on the primary side, and if this blows the current must be kept down by means of a water rheostat connected in series in the circuit, so that a new fuse won't blow.

The water rheostat need only consist of an iron bucket to which one wire is attached and the other wire connected to a piece of metal and placed in the center of the bucket in the salt water with which the latter is filled. The current can be increased by moving the metal electrodes toward the side of the bucket.

Care should be used to see that the pipe to be thawed is disconnected from all other piping in the building. If this is not done, there is a possibility that the major portion of the current may be bypassed around the freeze and the job will be a failure or require considerable more time than necessary.

If alternating current is not to be had, one or more 110-amp.-hr. storage batteries can be utilized at a high discharge rate, but care should be taken not to use a rate which would damage the batteries. Slight freezes can be taken care of in this way, but several batteries would be needed if the heating required more than half an hour. **William R. Bryans.**

New York City.

Repairing a Steel Stack

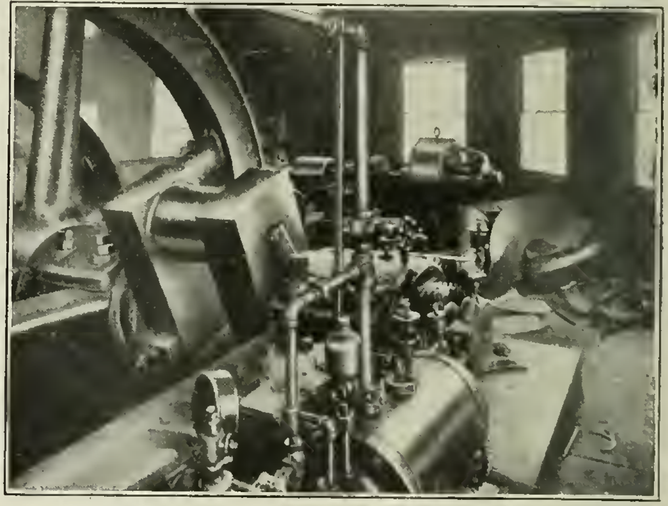
Some time ago in our plant a steel stack rusted off at the base, and we were confronted with the problem of how to put in a new section without taking down the whole stack. The difficulty was overcome by building a scaffold around the stack and lifting it by a block and tackle to a sufficient height to allow the new section to be put in; then the top part was let down and riveted to the new section, thus making the repair without the extra work of lowering and raising the entire stack.

Philadelphia, Penn. **D. R. Hibbs.**

Piston, Striking Head, Wrecks Engine

The engine wreck shown in the illustration is similar to many others that have occurred in the past and, like many others, was due to neglect and lack of lubrication of the main-crank bearing, which caused the engine in time to get too much lateral motion in the main moving parts and allowed the piston to come in contact with the cylinder head, resulting in the general wreck, as shown. The engine cylinder was 16 x 24 in., the speed 150 r.p.m. and the working compression 260 lb. The balance weights, which were distributed over the plant, weighed approximately 3600 lb., and a connecting-rod, which was thrown some distance, weighed about 1500 lb. The accident not only wrecked the machine as shown, but cracked the main bedplate in several places. **C. R. McGahey.**

Atlanta, Ga.



WRECK CAUSED BY PISTON STRIKING CYLINDER HEAD

It is better to wear a Liberty Bond button on your coat than the print of the Kaiser's heel on your neck.

Do you believe in Democracy? Do you believe in America? A purchase of a Liberty Bond is a test of your faith in American Democracy.

When you lend money to the Government it does more for you than you do for it. The Government pays good interest and protects your life and property.

Inquiries of General Interest

Burning of Clean Water Tubes—What would cause clean tubes of a water-tube boiler to become burnt or blistered below the water line of the boiler? L. G.

The material of water tubes or other heating surfaces of a boiler is likely to become burnt when the fire is driven so hard that the rapid generation of steam drives the water away from the heating surface, as that condition causes the surface to become overheated from much slower transfer of heat than when the water is directly in contact with the heating surface.

Mean Forward and Mean Effective Pressure—What is the meaning of "mean forward pressure" and "mean effective pressure"? W. P. S.

"Mean forward pressure" is a term used to designate the average pressure acting on a piston with a tendency to move it forward, or in the direction corresponding to that necessary for performance of useful work. It is the reverse of mean back pressure, which is the average pressure that resists the motion of a piston in performance of useful work. "Mean effective pressure" is the mean net pressure that urges a piston forward, and therefore is equal to the mean forward pressure minus the mean back pressure.

Inches of Water Pressure—What is meant by an inch of water pressure; and how many pounds or ounces per square inch would a pressure of 2½ in. of water be equivalent to? N.A.

An inch of water pressure signifies the intensity of pressure due to a column of water 1 in. high. As 1 cu.ft. of water at 62 deg. F. weighs 62.355 lb., the weight of 1 cu.in., or the pressure per square inch exerted by a water column 1 in. high, would be $62.355 \div 1728 = 0.03609$ lb. Hence 2½ in. of water pressure would be equivalent to $0.03609 \times 2\frac{1}{2} = 0.09022$ lb. or $0.09022 \times 16 = 1.4435$ oz. per sq.in.

Discharge from Broken Gage-Glass—If in case of breakage of a water-gage glass of a boiler under steam, the top connection is closed but the bottom connection cannot be closed, would escape of hot water and steam from the broken glass be prevented by opening the valve on the blowoff pipe to the column or glass? H. W.

Discharge from the broken glass would not be prevented, as opening a blowoff valve would relieve only part of the pressure holding the water up in the column. The water level in the column would become lower and as soon as the level dropped below the open gage-cock, steam would blow through the cock and it would be discharged from the broken gage-glass at the full pressure of the boiler.

Exhaust-Steam Heating with Back-Pressure Valve Open—Can an exhaust-steam heating system, supplied with exhaust from a noncondensing engine, be operated with the exhaust back-pressure relief valve left open? C. P. C.

The purpose of a back-pressure relief valve is to hold sufficient pressure to satisfy the heating system, to relieve excessive back pressure and to act as a check valve to prevent admission of air in case the heating system draws the pressure below the pressure of the atmosphere. Hence the back-pressure valve may be left open so long as the pressure of the exhaust at the point where the heating supply is taken off is high enough for the heating apparatus, or the effect of the heating apparatus is not to reduce the pressure at the back-pressure relief valve below the pressure of the atmosphere.

Setting Valve of Single-Valve Automatic Engine—What is the method of setting the valve of a single-valve automatic shaft-governor engine? J. W. M.

The valve setting will consist mainly of adjustment for equalizing the cutoff. If cutoff takes place earlier on one end of the cylinder than the other, then with other portions of the valve gear properly assembled, the cutoff can be equalized by lengthening or shortening the valve-rod connections to obtain diagrams that would be desirable when the engine is driving the average load. If indicating is not available, the cutoff can be approximately equalized by blocking the governor to a position of about one-half its range of motion and adjusting the valve-rod connections to obtain closing of the steam valve at the same fraction of stroke from both ends, when the engine is turned over.

Kerosene as Boiler-Scale Remover—What are the advantages and disadvantages of using kerosene for removing scale from a boiler?

In cases where boiler scale is of such a nature that it can be softened by introducing kerosene along with the feed water, the oil has the advantages of being a cheap and conveniently applied scale remover. The leading objections to its use are that the presence of oil in a boiler is likely to cause leaks at joints and rivets; steam-joint gaskets of rubber and many other materials disintegrate and leak from presence of oil; and deposits of heavier oils may be formed which, combining with material contained in the feed water, may cause the heating surfaces to become burned. Boilers containing traces of mineral oils, especially when the oil has been liberally added to the feed water, should be thoroughly washed, drained and ventilated before being entered, as highly inflammable hydrocarbon gases are likely to be present.

Failure of Corliss Engine-Governor Belt—What would result if the governor belt of a Corliss engine should break or come off the pulley? W. F.

The governor would stop, and with the governor balls no longer acted upon by centrifugal force, they would drop to a position of support. If permitted to drop to the very lowest position for which the governor is designed, the safety cams, if properly set, would be drawn around to a position for which the steam admission valves are not opened, and the engine would come to rest. But if the governor is hindered from dropping far enough to bring the safety cam to this position, as for instance, from resting on the starting pin or other device used to support the governor for holding it up to a starting position, then the valves will be operated to admit steam without the governor's regulation of the cutoff. Under these conditions, unless the supply of steam is shut off by hand or by some form of automatic safety stop, the speed is likely to increase sufficiently to wreck the engine.

Drilling and Reaming Boiler Rivet Holes—Why are boiler rivet holes required to be drilled or reamed in place of punching the holes to size? J. R. L.

Punching lessens the tensile strength of the material around the holes, and the pressure of the punch, and difference of diameter of the punch and die, cause jagged-edged holes and burrs that reduce the holding power of the rivets. In addition to this, holes punched in two or more thicknesses that are to be riveted together seldom come in correct register. By first punching the holes smaller than required for receiving the rivets, the rough edges and distorted material can be removed by drilling the punched holes to size, and the holes of two plates that are to be riveted together may be brought into alignment by drilling the holes full size with the plates bolted in position. The strength of the remaining material is considered to be unimpaired for plates over 5/16 in. thick when the diameter of the punched holes does not exceed ¼ in. less than the finished diameter, and for plates not exceeding 5/16 in. thick, when their diameter does not exceed ⅛ in. less than the finished diameter.

ERRATUM: The result of the computation given in the first item, page 377, Mar. 12 issue, as "about 9000" should have been "about 49,000 lb. of steam per hour."

Coal Saving by Lighting Curtailment*

BY PRESTON S. MILLAR

The author points out that the coal used in the production of electric light is less than 2 per cent. of the total coal output of the country, and that any practical curtailment is about 7 per cent., which means about 840,000 tons of coal per annum, or a trifle more than 0.1 of 1 per cent. saving. It is possible to effect much larger savings by other methods with less disadvantage to the public.

THE most important thing is to win the war. Need for directing money, energy and materials toward the prosecution of the war makes it imperative that waste and extravagance be eliminated. The first consideration is how best to contribute to victory. Economy, in lighting, as in other things, is one means toward that end. Economy in lighting in the present circumstances depends upon:

Securing best accomplishments of the results which the lighting is intended to bring about, subject to the need for reducing the consumption of fuel by the elimination of unnecessary lighting and by reduction of other lighting so far as the emergency warrants. Emergency reduction should be undertaken after due consideration of:

a. The amount of fuel saving that can be accomplished.
b. The disadvantages involved in the reduction.
c. The practicability of saving the same amount of fuel otherwise with less disadvantage.

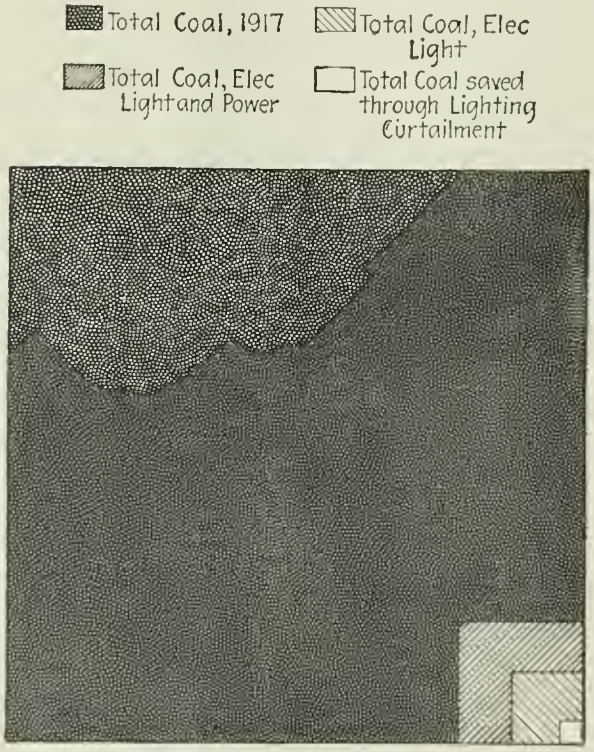


FIG. 1. TOTAL COAL PRODUCTION AND COAL CONSUMPTION OF THE COUNTRY FOR LIGHT AND POWER

The cost of artificial illumination of all kinds is 0.5 to 2 per cent. of the total expenditure of the people. It compares with certain other expenditures as follows: Illumination, $500,000,000; liquors, $665,000,000; and tobacco, $490,000,000.

The significant figures to have in mind in discussing this subject are as follows, all being rough approximations: Total coal output of the country, 640,000,000 tons; total employed in production of electric light and power (traction excluded), 36,000,000 tons; total employed for production of light by electricity, 12,000,000 tons. According to these estimates, about 2 per cent. of the coal consumption of the country goes into electric light. Fig. 1 gives a graphic comparison between the foregoing figures and the estimated coal saving possible by lighting curtailment.

Some comparison may assist to provide a proper perspective for the consideration of these data. Coal shortage, the equivalent of which must be saved, 50,000,000 tons, estimated savings in coal during 1914 if all private plants could have been replaced by central-station power, 13,000,000 tons. Estimated saving in coal by maintaining temperature of building interiors at 67 deg. F. instead of 70 deg., 10,000,000 tons.

It is evident, therefore, that the total consumption of coal in the production of all electric light is relatively not a very large item in the coal consumption of the country. If the entire electric lighting of the country were cut off, the saving in coal would be only 24 per cent. of the required saving, and no more than would be accomplished by a reduction of readily practicable extent in the heating of buildings. In considering lighting curtailment, therefore, it is important to bear in mind that even if every candle power of electric lighting were wasted, the loss of coal involved would not be the great outstanding coal waste of which this country is guilty. As relatively little light is wasted, it is evident that the amount of coal which can be saved by electric-lighting curtailment is small.

RECOMMENDED ADJUSTMENT OF ILLUMINATION INTENSITIES IN VIEW OF THE WAR AND THE FUEL SHORTAGE

Class of Lighting Service	Per Cent. Distribution	Desirable Adjustments in Intensity Per Cent.
Street	15	— 5
Public building	3	— 10
Industrial	18	+ 50
Protective	1	+200
Commercial	20	— 20
Residence	26	— 20
Recreational	7	— 40
Advertising	5	— 80
Miscellaneous	5	— 10
Total	100	Net — 7

The author has prepared the rough estimate given in the table, showing the adjustment of illumination intensities, which according to expert opinion of several men engaged in the lighting business ought to be made from standards existing before the war, in view of the war and the coal shortage. The table also shows the manner in which artificial lighting is distributed among the several classes of service adopted as a classification for this purpose. There are no general statistics on this subject. Therefore, these figures should not be accepted as anything more than a rough approximate, although they are probably reasonably indicative of expert opinion on this subject at the present time.

The first adjustment of artificial lighting which ought to be made at the present time depends on the one hand upon the need for obviating extravagant lighting and eliminating waste, and on the other hand upon the importance of promoting industry and safeguarding lives and property. The net adjustment based upon the estimates of opinions summarized in the table is in the order of —7 per cent. Adjustment in particular classes of service range from a maximum curtailment of —80 per cent. in advertising lighting to a net increase of 200 per cent. in protective lighting. In the opinion of lighting experts, electric lighting, which to obtain most desirable value ought to be increased by 73 per cent. before the war, ought now to be decreased by 7 per cent.

---

*Abstract from a paper presented at the special meeting of the Illuminating Engineering Society in New York City on Feb. 14, 1918, and at a meeting of the Philadelphia section of this society on Feb. 15, 1918.

Various methods of reducing artificial lighting as a war measure have been proposed as follows:

Remove unnecessary lamps, extinguish all lamps when they are not in use, extinguish some of the lamps when possible, substitute smaller sizes of lamps, and replace inefficient by efficient lamps.

There is every reason for emphasizing the desirability of eliminating the unnecessary use of light. Fuel administrators and lighting companies have urged this expedient very prominently. Bulletin V of the Committee on Coal Conservation of the Chamber of Commerce of the United States, entitled "Conservation in Use of Coal," is an excellent presentation on this general subject which should be distributed generally.

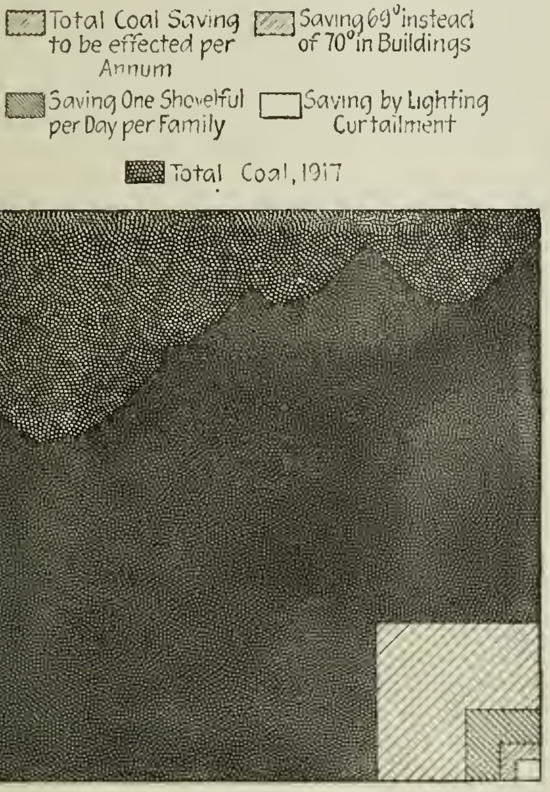

FIG. 2. TOTAL COAL PRODUCTION AND COAL SAVINGS BY DIFFERENT CURTAILMENTS

To arrive at suggestions for saving fuel used for lighting purposes without deleterious effects, one should consider the elements of inefficiency in lighting and the possibility of eliminating them. Such a line of consideration brings the following to the fore:

Good utilization of light, good maintenance of lighting equipment, use of good reflecting surfaces, daylight saving, utilization of water power, and elimination of small power plants.

The adoption of summer daylight saving, as now proposed, is estimated to be capable of reducing the coal consumption of electric central station steam plants by 230,000 tons per annum for the entire country. A suggestion to advance the period of activity by one hour the entire year round, which is now attracting considerable attention, is estimated to afford about the same saving to the public in lighting bills, but to result in a somewhat greater saving of coal on account of the more favorable load factors for the power plants, which would result in the winter months.

The inherent lower efficiency of small plants, together with less expert operation, which in general they receive, is estimated to be responsible for the use of one-third more coal than necessary. This element of waste is even more serious in England than in this country, as is evidenced by a recent report (April 16, 1917) of the Coal-Conservation Sub-Committee of the Reconstruction Committee, in which, after pointing out that the average capacity of English generating plants is 5000 hp., it is stated that "the present coal consumption if used economically would produce at least three times the present amount of power."

If a proportional amount of coal saving equivalent to 7 per cent. of the total electric light produced be assumed, this would mean a reduction in coal consumption of 840,000 tons per annum. This is the maximum extent to which it is believed that the best interests of the public requires coal to be saved through electric-light curtailment. Such a saving compares with other possible annual savings as follows:

Total savings which must be accomplished, 50,000,000 tons; net savings thought desirable through curtailment of electric lighting, 840,000 tons; savings if one degree lower temperature is adopted for building interiors, that is, 69 instead of 70 deg. F., 3,000,000 tons; and saving if each family decreased by one shovelful its daily use of coal, 15,000,000 tons. A graphic comparison of these figures is given in Fig. 2.

The saving which is possible in the heating of buildings looms large. Our practice in this respect is to heat buildings to a considerably higher temperature than is done in Europe. The coal which might be saved by operating buildings at temperatures which prevail in Europe, instead of at the temperature which we affect, would be more than the equivalent of the entire consumption of coal in electric lighting. Even the saving of one shovelful of coal per day makes any practical saving through electric lighting curtailment seem very small

New York State Legislation Affecting Power Interests

A synopsis of the more important bills affecting power interests introduced in the Legislature at Albany follows:

Senate Print No. 1. Amending the Public Service Commissions law, by providing that whenever a gas or electric corporation or a municipality files with the commission a new schedule of rates or a change in form of contract as to rates, service or facilities, the commission may, upon complaint or of its own initiative and upon notice, hold a hearing concerning the propriety of the proposed change and pending a decision may suspend it for not exceeding 120 days from the date when it would otherwise take effect. On Feb. 13 this bill was on the calendar in the Senate for final passage, but was recommitted to the Public Service Committee and has not since been called out.

Senate Print Nos. 66, 67 and 68 are three companion bills providing for the erection of a state owned and controlled hydro-electric power plant at Niagara Reservation. They provide for the issue, after approval by a referendum, of $3,000,000 of tax-exempt bonds, empower the Niagara State Reservation to construct such power plant and to operate it under their own management or under lease and provide for the manner of construction. Neither one of the measures has as yet been reported for consideration.

Senate Print No. 271. Amends the Public Service Commissions law relative to complaints as to quality and price of gas, by providing that upon written petition of not less than 100 users of gas or electricity in first- or second-class cities, and not less than 50 such users in third-class cities and 25 elsewhere, the mayor, village trustees or town board, as the case may be, must complain to the proper commission regarding the matters specified in the petition. This bill has not been acted on in the Senate. The same bill introduced in the Assembly under print number 404 on Mar. 7 was reported to second reading.

Senate Print No. 475. Amends the Public Service Commissions law by empowering the commission to raise or reduce rates and charges for gas and electricity, notwithstanding a rate may be fixed by statute or otherwise. No action has been taken on this measure.

Senate Print No. 428. Creating a state hydro-electric power commission to consist of the Governor or a representative appointed by him, Lieutenant-Governor, Attorney-General, State Engineer and the Conservation Commissioner, to investigate costs and method of development, transformation, transmission and distribution of the water powers of the state, formulate a definite and fixed policy of utilizing same, including canals; prepare and recommend proper legislation for carrying out such plan and urge upon the Federal Government proper recognition of the state's inherent right to full control of the boundary waters; and may authorize the Attorney-General to bring action against the Federal Government to determine such rights. One hundred thousand dollars is appropriated. The commission may maintain a bureau at Washington, D. C. This bill is the result of the labors of the Thompson water-power investigating committee which has been busy the last two years. At this writing it cannot be determined what action the Legislature will take in regard to the passage of the measure.

Senate Print No. 430 authorizes the Superintendent of Public Works with the approval and direction of the Canal Board, to lease the use of surplus waters impounded by canal dams and flowing into canals; authorizing the Canal Board to compromise and adjust claims and demands of water-power claimants and owners of water-power rights and privileges, appurtenant to state canal dams, constituting part of improved canals. The surplus waters of canals are to be leased to the highest bidder whether it be a person, corporation or municipality. Leases must not be for less than the appraised value of such water, and every ten years the value is to be reappraised. The Legislature has taken no action on the passage of this measure, but it will undoubtedly come up for discussion before the adjournment.

Senate Print No. 542. Authorizes the state through the Canal Board to build and equip canal boats and other craft, or to purchase or lease them for a period not longer than one year after the war. The state may lease such craft to individuals or corporations for operation or may operate them itself through the Department of Public Works, which is empowered to fix transportation rates. The Canal Board may organize one or more stock companies for constructing, purchasing or leasing such craft and for their operation, the aggregate capital not to exceed $2,000,000. If the state remains stockholder, it must retain at least 51 per cent., selling the remainder to the public at par. The Canal Board may with the governor's consent sell the entire issue to the public. One million dollars is appropriated. This measure is said to be favored by the Governor and will undoubtedly meet with the serious consideration of the Legislature before its adjournment. It bears upon the question of transportation and coal supply.

Senate Print No. 597. Amends the second-class cities law by permitting a municipality to construct, own, maintain and operate an electric power plant with necessary equipment for supplying electric power and light to the municipality itself.

Senate Print No. 744. Amends the railroad law by prohibiting the use of a locomotive engine not equipped with a vestibule cab so constructed as to attach to the sides of and inclose all openings between the engine cab and the water tank or coal tender. It strikes out the provision that mechanically operated doors are not required on doors of locomotives equipped with mechanical stokers. This bill has not been reported from committee.

Senate Print No. 747, by Senator Wagner, is a municipal-ownership public-utilities bill introduced as the outgrowth of campaign pledges in the recent New York mayorality campaign. It amends the general city law giving all cities power to own, construct, acquire, purchase, maintain and operate plants, facilities and property of every kind for supplying light, heat, power and transportation for both municipal and private use. Intention to exercise such power must be evidenced by resolution of the local administrative body declaring it in the public interests to do so and giving general description of the facilities or property to be constructed or acquired. The propositions must be submitted to the electors of the city. The value of the property to be acquired must be ascertained in the first instance by the Public Service Commission. There are various other provisions. What action the Legislature will take on this bill is largely a matter of conjecture.

Senate Print No. 842. Amends the labor law by extending the provisions for boiler inspection by the Industrial Commission to include all boilers for generating steam or heat, which carry a pressure of over 15 lb. to the square inch instead of 10 lb. as at present, and whether used for factory purposes or otherwise, except boilers subject to inspection by the United States Government or Public Service Commission; requiring such inspection at least once a year.

Senate Print No. 889. Amending the Public Service Commissions law by authorizing incorporation of gas corporations for acquiring natural gas and distributing and selling same, giving such corporation the right to acquire necessary artificial gas to augment its supply by purchase, manufacture or otherwise, and empowering the public service commission to order such augmentation when necessary for adequate service to customers.

Senate Print No. 902. Amending the Public Service Commissions law by requiring the commission to establish gas-testing stations for each individual gas corporation at points remote from the gas plants, and providing a schedule of fines based on the percentage of inferiority in gas, such penalties to be in the form of rebates to the customer.

Assembly Print No. 54. Amending the Transportation Corporations law by prohibiting electric-light corporations from collecting rent from meters. This law already applies to gas meters.

Assembly Print No. 472. Appointing Benjamin B. Odell State Ice Comptroller and regulating the storage and distribution of natural and artificial ice. It prohibits the manufacture of artificial ice in New York City, on Long Island and the counties bordering the Hudson River between Mar. 1, 1918 and Feb. 1, 1919. This bill passed both houses of the Legislature and became Chapter 4 of the Laws of 1918.

Assembly Print No. 645. Amends the conservation law by creating a division of hydro-electric power in the conservation department. This is a socialist measure and calls for the development of the Niagara River, the Long Sault Rapids and all inland waters and streams. Twenty million dollars of 4½ per cent. bonds are to be issued if the people approve of their issue at a referendum to be submitted to them this fall. The measure has to pass the Legislature, however, before it can be thus submitted.

Assembly Print No. 346. Provides for a terminal improvement commission in New York City, consisting of the mayor and comptroller, two public-service commissioners, First District, designated by the Governor, and three other members appointed by the Governor with the consent of the Senate to adopt plans for comprehensive terminal facilities for freight and for terminal markets in Manhattan. The commission may enter into an agreement with the New York Central and other transportation corporations, or if an agreement cannot be reached it may order compliance with plans adopted by it. The commission may order joint usage of facilities by different corporations. Until the Legislature determines that adequate terminal facilities have been completed, the commission is to exercise all the powers of the Public Service Commission over such terminals in Manhattan. When so completed the commission's existence is terminated. Provision is made for the condemnation of property, lease or exchange of lands with city, and for enforcement by courts.

Assembly Print 1098. Empowers the Public Service Commission by order to require two or more telephone corporations to establish continuous and through lines of communication, as in the case of telegraph corporations as at present.

Assembly Print No. 334. Empowering the Public Service Commission to raise or reduce rates and charges for gas or electricity, notwithstanding a rate may be fixed by statute or otherwise.

Steam Heating at Camp Funston

Before the Kansas City Chapter of the American Society of Heating and Ventilating Engineers, B. Natkin read an interesting paper on "Heating of Army Camps and Cantonments," dealing in particular with the installation at Camp Funston. Of the 16 National Army cantonments the following four are mainly heated by steam: Camp Custer, of Michigan; Camp Devens, of Massachusetts; Camp Funston, of Kansas; and Camp Grant, of Illinois.

All were installed under the same general plan with minor alterations to suit local conditions, so that a description of the heating plants at Camp Funston will practically apply to the other three camps.

Camp Funston is situated three miles from Fort Riley in the central portion of Kansas on a Government reservation of about 1200 acres. There are erected on these grounds 1400 wooden buildings, inclusive of barracks, latrines, medical quarters, officers' quarters, stables, garages, heating plants, exchange stores, warehouses and amusement buildings. Of this number, 650 buildings are heated from a central steam plant, while the balance have individual plants, stove or furnace heat, with the exception that the stables, garages and warehouses have no heat.

For heating these buildings there are 18 separate boiler plants, each taking care of about 35 buildings. Steam is supplied by a system of overhead mains supported on poles, and the condensation from each building is wasted. Steam in the main line is carried at 50-lb. pressure and is reduced at each building to about 5 lb. A 2½-in. reducing valve is used in each barrack and two 1¼-in. valves in each latrine, one for the radiators and the other for the hot-water tank. There is a total of 965 reducing valves in the camp. The poles are 20 ft. apart, and the steam main is suspended about 15 ft. in the air from trapeze hangers. The average size of the main is about 5 in. and the average run is 1200 ft. The drop in pressure at the end of the main is about 20 lb. Expansion is taken care of by slip joints at 200-ft. intervals. Branches to the various buildings are taken off at the bottom of the mains. By this means the lines are drained approximately every 75 ft. The steam mains are covered with 1 in. of asbestos air-cell covering, then 1¼ in. of wool felt, over which is wrapped waterproof roofing paper securely wired.

Overhead lines were used in preference to underground because this system was cheaper to install, could be readily got at for repairs, and material could be obtained more readily. As no return-line system was installed, a single line served the purpose. If the system was laid underground it would necessitate miles of trenching, suitable underground covering, such as wood log or insulated tile, a parallel return main with traps to take off the condensation in the mains and a drainage system for keeping the line dry. Then there would be the greater difficulty of repair. The condensation in the overhead line is little greater than generally occurs in an underground line.

Lack of an abundant supply of water, together with its large percentage of scale, has made it necessary to install a return-line system to save the condensation. These lines are now being installed. They run to a central low point in each unit, where the condensation is collected by an electric-driven pump and receiver, which in turn discharge the water to the boiler room. It is quite probable that had the Government engineers foreseen this necessity of underground return lines, they might have put the steam lines also underground, as it would have proved less expensive than the present system of overhead lines and underground returns.

Each boiler house has four 72-in. x 18-ft. hand-fired tubular boilers rated at 150 hp. each and served by individual 34-in. steel stacks 60 ft. high. Each plant takes care of about 35,000 sq.ft. of radiation, there being a total of 600,000 sq.ft. in the 18 units. Outside of the boilers, the only equipment in the boiler house is a 6 x 4 x 6-in. duplex boiler-feed pump and a small heater built of 8-in. pipe utilizing the exhaust steam from the pumps. Three boilers are fired as a rule, with the fourth in reserve for extreme cold weather.

The organization used to handle the central plants at Camp Funston is made up as follows: Two firemen are employed for each boiler, each man taking his turn for a twelve-hour shift. Two foremen are employed to watch groups of three plants. Over the foreman is the superintendent of the heating plants, who works under the head of the Department of Camp Utilities. The civilians employed in the various boiler plants are fast being replaced by soldiers, who will eventually handle the plants.

Barracks are two-story buildings 140 x 43 ft. The radiation installed in the barracks is all of the three-column, 38-in. high, cast-iron type. Three or four radiators in a row are connected together at the bottom by a 2-in. pipe, the steam feeding from one radiator into another. One valve controls the three or four radiators that are connected together. A steam main ends at each corner of the barrack and is connected into a steam trap, discharging upon the ground under the building.

The second-story squad rooms are heated by 14 radiators, totaling 810 sq.ft. Using a factor of 88 B.t.u. loss per hour per square foot of glass, 24 B.t.u. for exposed wall and 1.43 B.t.u. loss per hour per cubic foot of contents, these squad rooms would require 762 sq.ft. of radiation to heat them to 70 deg. in weather 10 deg. below zero. The loss through the roof is disregarded, as there is a dead-air space of about 4 in. between the beaver board and the roofing through which the air does not circulate, thus forming a fairly good insulation. The first-story squad room is heated by seven radiators, totaling 385 sq.ft.

The radiation installed in the barracks has been keeping the soldiers comfortable during the cold snaps that have occurred this winter. At night all upper windows in the squad room are opened, and trouble was experienced during the cold weather from radiators freezing. To conserve the water and fuel and prevent freezing, the steam is now turned off the barracks after the soldiers have retired for the night.

Besides the 18 central heating plants there are 42 individual steam-heating plants for officers' quarters and infirmaries, carrying loads of from 280 to 3900 sq.ft. each. These buildings are heated on the two-pipe gravity plan using cast-iron boilers and radiators.

Near the center of the camp is the big amusement zone, which comprises four blocks, 150 x 250 ft., with buildings of a permanent character, having stuccoed fronts. There are theaters, restaurants, dry-goods stores, pool hall, shooting gallery and other buildings which contain a total of 45,000 sq.ft. of radiation. For this zone a two-pipe vacuum heating system is used. Steam is supplied from a central heating plant of 600-hp. capacity, having four 72-in. x 18-ft. return-tubular boilers set in a battery. The other boiler-house equipment consists of one 700-hp. feed-water heater, two 6 x 4 x 6-in. boiler-feed pumps, two 10 x 14 x 12-in. vacuum pumps, one 3000-gal. per hour hot water heater, one 3000-gal. per hour deep-well pump, one 48-in. x 24-ft. pressure tank and one large receiving tank.

Boiler connections of 6 in. diameter lead into a 12-in. drop header. From this two 5-in. leads are taken, each of which passes through a 5 x 10-in. pressure-reducing valve in the boiler house. The 10-in. lines supply heat to the various buildings. No piping is run exposed outside of the buildings. The steam and hot-water supply mains are run in the attics or on the ceilings of the buildings and drop under the streets in wood conduit in a trench back of the buildings.

Builds Small Hydro-Electric Plant

North Wilkesboro, a small town in North Carolina, will soon be operating its own hydro-electric lighting station with a day and night service. The new plant is nearly completed and the only remaining machinery to be installed is the electric apparatus, which has been selected with a view to fulfilling the needs of the city for a long time to come. Although the town has a population of but about 2000, it is setting an example worthy of many others to follow, in that an available water site is being utilized for producing electrical energy.

Heretofore there has been trouble in generating sufficient energy by steam power, which was not only expensive, but could not be generated in quantities sufficient for both day and night service, on account of the scarcity of coal. With the water-power plant in operation the question of coal will be a thing of the past and power will be generated from a source that has been allowed to go to waste day after day, while valuable coal has been burned in producing power that could have just as well have been generated by water.

Forty-seven Coal Dealers Indicted

In response to *Power's* editorial request, in the issue of Feb. 26, for the names of Tennessee operators and dealers indicted for fuel-law violations, a correspondent has sent in a copy of the Knoxville *Journal and Tribune* for Feb. 15, containing a report from which the following is abstracted:

Violations of the Lever fuel control act and price-fixing regulations of the National Fuel Administration are charged in 23 indictments, naming 47 separate defendants and containing 163 counts, which have been returned by the Federal grand jury. Some of the largest coal companies and best known mine operators, wholesalers and retailers of coal in east Tennessee are made defendants. Charges against the defendants include conspiracy to violate the Lever law, filing of false and fraudulent reports with the Federal Trade Commission and the sale of coal at unlawful prices.

Should the defendants be found guilty, they are subject to maximum fines of $5000 on each of the 163 counts, or imprisonment in the United States penitentiary at Atlanta for not exceeding two years, or both fine and imprisonment.

Evidence in the cases was gathered by Arthur J. Delvin, D. H. Littleton, F. S. Shipp and Ernest Hawkins, special agents of the Department of Justice during an investigation which lasted more than two months. Further investigations are to be made, and, if developments justify, the results will be presented to the Federal grand jury which meets in Knoxville on the fourth Monday in May.

John Q. Barker and William C. Barker, of the Barker Lumber Co., coal brokers, of Knoxville, and E. Scott Miles and the Sequatchie Coal Co., coal brokers, of Chattanooga, are named as defendants in an indictment containing 19 counts, one of which alleges conspiracy. John Q. Barker and William C. Barker are made defendants in separate indictments on a charge of having filed false and fraudulent reports with the Federal Trade Commission, reporting the coal handled by them.

The following companies and individuals are named as defendants in an indictment containing 27 counts, two of which allege conspiracy to violate the Lever act: A. Gatliff, T. B. Mahan, E. C. Mahan, N. B. Perkins, L. F. Pratt, C. G. Ellison, N. A. Archer, Gorman Jones, Wiley W. Thomas, J. D. Williams, Southern Coal and Coke Co., New Caryville Coal Co., Sun Coal Co., Gatliff Coal Co., Mahan-Jellico Coal Co., Southern Mining Co., Golden Ash Coal Co.

D. C. Campbell, of the D. C. Campbell Coal Co., is named as defendant in a 14-count indictment, alleging the sale of coal at unlawful prices.

The Superior Coal Co., S. T. Buffet and W. C. Whitaker are named as defendants in a 10-count indictment, alleging the sale of coal at unlawful prices.

The Hackney Coal Co. and Walter M. Miller are named as defendants in an indictment charging the retail sale of coal at unlawful prices.

Hugh B. Miller and Beatrice Hutchens, of the Knoxville Coal Co., are named as defendants in an indictment charging the sale of coal at a retail price of $10.40 per ton when the Government price was not exceeding $6.25.

The Sun Coal Co. is named as defendant in an indictment of 8 counts alleging the sale of coal at unlawful prices.

The New Caryville Coal Co. is named as defendant in a 6-count indictment alleging the sale of coal at unlawful prices.

The Terry, West Coal Co. and A. C. Terry, of Oneida, are named as defendants in a 13-count indictment alleging the sale of coal at unlawful prices.

Tallman Sexton, Clifford Sexton, R. S. Barnes and B. L. Sadler, doing business as the Oneida Coal Exchange, of Oneida, Tenn., are named as defendants in an 11-count indictment alleging the sale of coal at unlawful prices.

The Southern Jellico Coal Co. and Walter L. McKinney, of Jellico, are named as defendants in an 11-count indictment charging the sale of coal at unlawful prices.

Wymer B. Siler, of Jellico, is named as defendant in a 7-count indictment charging the sale of coal at unlawful prices.

Ray Buell, J. L. Lindsay, of Jellico, and Clyde Rhodehaver are named as defendants an indictments charging the sale of coal at unlawful prices.

I. C. Stonecipher, of Scott County, is named as defendant in a 3-count indictment charging the sale of coal at unlawful prices.

W. M. Pierce, of Jellico, is named as defendant in a 3-count indictment charging the sale of coal at unlawful prices.

T. C. Williams, of Jellico, is named as defendant in a 3-count indictment charging the sale of coal at unlawful prices.

John C. Pemberton, of Oneida, is named as defendant in an 18-count indictment charging the sale of coal at unlawful prices.

J. T. Moore, of Jellico, is named as defendant in a 5-count indictment charging the sale of coal at unlawful prices.

These indictments cover a wide field of alleged violations of the Lever act, says District Attorney Kennerly, from conspiracy to violate that law to alleged violations of the prices fixed by President Wilson regarding the sale of coal at wholesale, in car lots, down to small retail sales of from three to five bushels.

Recently, the Federal grand jury at Covington, Ky., returned indictments against 61 coal operators, operating mines and handling coal in eastern Kentucky. Many of these Kentucky defendants, it is claimed, operated in connection with the Knoxville coal brokers and dealers, selling their output, which was marketed through the agency of some of the defendants named in the Knoxville indictments.

How to Join the Army Engineers

The Kaiser has placed the keenest engineering talent of his own and allied empires into the imperial armies of the Central Powers to defeat the world. During these last three years the best engineering skill of France, Great Britain, Russia and Italy and their Allies have been matched against the enemy. American employers are paying engineers such attractive salaries that voluntary enlistments of the high-class technical men in the United States Army are below requirements. This deficiency is also probably due in part to the lack of proper information concerning the engineering branch of the service. Few civilians know that it is possible for them to perform in the Engineering Corps almost exactly the same kind of work in which they are at present engaged.

The best results in any organization are obtained only when the energies of all the men in it are concentrated along the lines for which they are best suited by natural ability, education and training. The First Replacement Regiment of Engineers was organized at Washington Barracks, D. C., on December 14, 1917, with the express idea of accomplishing this end. Its specific purpose is to keep all engineering units of the Army at full enlistment strength during the period of this war. This régiment has not only the responsibility of finding men to fill up depleted ranks, but it must also fit them to step into the work of trained, efficient and disciplined soldiers.

The preliminary work of the recruit is first a thorough training in military drill, for the engineer soldier must be prepared to lay down his shovel and take up his rifle at any time. Infantry drills gradually give way to engineer work and more specific technical training. The engineer soldiers must know how to tie all the important kinds of knots and lashings, to build spar and truss bridges, to construct revetments, dig trenches, place wire entanglements, construct machine-gun emplacements, build pontoon bridges and to construct roads. They must also know the methods of demolition, sapping and mining. Specialized training in lithography, zincography, surveying, mapping, photography, carpentery, blacksmithing, electricity and machinery are also given to those qualified for further training in any of these branches.

The Replacement Regiment will be called upon to furnish men for the following organizations: Camouflage regiments, crane-operating and maintenance regiments, depot detachments, electrical and mechanical regiments, forestry (sawmill) battalions, forestry (auxiliary road, camp and bridge) battalions, gas and flame service, general construction battalions, mining regiments, quarry regiments, sapper regiments, searchlight regiments, supply and shop battalions, surveying, ranging and map-reproduction regiments, water supply companies.

Engineers are called upon to perform such a wide range of work that practically every man with any technical training or mechanical ability can find a place in this organization. Every male citizen in the United States who is physically fit, and between the ages of 18 and 21, and 31 and 40, is eligible to join the regiment by voluntary enlistment.

The applicant should write to the Commanding Officer, First Replacement Regiment Engineers, Room 107, Headquarters Building, Post of Washington Barracks, D. C., for application blank. If the blank shows the man to be eligible, an enlistment card is filled out and sent to the recruiting officer nearest to the applicant's place of residence, with instructions to enlist the man for service in this regiment.

United States Steel and Pig-Iron Output

According to the *Iron Trade Review*, Cleveland, Ohio, the steel-ingot production in 1917, as estimated by the American Iron and Steel Institute, will be 42,600,000 gross tons and the pig-iron output, 38,500,000 tons. The former figure will mark a new record; the latter will mark a drop from the total pig-iron production of 1916. The ability of the steel industry to make a new production record in the year in which the United States entered the war will arouse great satisfaction among the country's friends. Germany's steel output sagged heavily after she opened hostilities, and yet she had a clearer appreciation than any other nation of the colossal tonnages of iron and steel which modern warfare demands. German "efficiency" could round up an immense, trained army overnight, but failed to mobolize simultaneously her industrial forces. America, with an army to find and equip, and with the handicaps which her inexperience and unpreparedness entailed, was able, at the same time, the *Review* states, to keep her steel furnaces in operation and to surpass her 1916 mark, itself a record. The decline in pig-iron output from 1916 is comparatively slight and is due to the difficulties met in assembling raw materials. The *Review* concludes by stating that the year's record production inspires confidence in the future. Germany's steel industry, when pitted against America's, is fighting a losing battle.

Signal Corps Wants Electrical Men

The Signal Corps, U. S. Army, has announced that it can use the services of a large number of men having electrical training. They are needed especially in connection with the radio communication systems in use in the military service. All classes of electrical men—wiremen, expert electricians, storage-battery men, telegraph and wireless operators, and men with electrical-engineering training and experience are wanted. The opportunity offered is exceptional because of the great interest and importance of this branch of the service which has been most aptly characterized as the nerve system of the army. Men engaged in the radio division of the communication work in particular have an increasingly important part in the great intelligence system upon which army operations are almost totally dependent. The scope of this work requires men who will fall in general into three classes, depending on the character and amount of experience had by the individual; namely, radio operators, radio mechanics and field radio experts.

Application blanks for service in the radio work of the Signal Corps may be secured by addressing the Office of the Chief Signal Officer, Land Division, Training Section, Washington, D. C. Men of draft age may make application and if qualified will be inducted into the army, at their request, for service in this branch of the Signal Corps. After enlistment or induction, all personnel will be sent to one of several radio schools for six weeks to three months of intensive training in one of the three general branches of the radio work for which their previous experience qualifies them. Some of the personnel completing these courses will be commissioned, and the opportunity for advancement for all graduates will be dependent on the individual ability.

Comparative Costs of Heating by Electricity, Gas and Coal

The following examples will give one an opportunity to determine the comparative costs of heating a building by electricity, gas, hard coal, and soft coal, by employing the figures or costs of fuels in his own locality.

The heating value of one kilowatt-hour is approximately 3400 thermal units—therefore, at 10c. per kw.-hr., one cent will purchase 340 thermal units. At $7.50 per ton hard coal—making available about 8000 thermal units per pound—one cent will purchase 21,333 thermal units. At this rate it would cost $62\frac{7}{10}$ times as much to heat with electricity as with coal.

The available heating value of one cubic foot of gas for heating purposes is approximately 600 thermal units per cubic foot. At 50c. per 1000 cu.ft., one cent would purchase 12,000 thermal units. With coal at $7.50 per ton—it would cost $1\frac{8}{10}$ times as much to heat with gas as with hard coal.

With electricity and gas on the same basis—but with soft coal—having a heating value of 6000 thermal units per pound and selling at $3.50 per ton—it would cost one hundred times as much to heat with electricity as with soft coal—and $2\frac{9}{10}$ times as much to heat with gas as with soft coal.—*The Ideal Fitter*.

Obituary

John P. Sparrow, chief engineer New York Edison Co., died suddenly of pneumonia at his home, Sunday, Mar. 17. A full account of Mr. Sparrow's career is now being prepared and will appear in our next issue.

Personals

Harry S. Potter has resigned as general manager of the Tarentum Glass Co. to become general manager of the Wellington Glass Co., Cumberland, Md.

C. W. Watkins, of Dorranceton, Penn., inventor and patentee of the Watkins automatic air-regulating furnace door, has sold his United States patent rights on the device to the Page Boiler Co., of Chicago, Ill.

Miscellaneous News

Launch Big Concrete Ship—The world's largest concrete ship, 7900 tons, christened the "Faith," was launched at a Pacific port Mar. 15. With the successful completion of the ship the construction of 54 similar vessels will start, according to her builders. The "Faith" was launched six weeks after the concrete was poured into the forms.

Fifty-eight Electric Companies operating in Pennsylvania have filed notices with the Public Service Commission that they propose to advance rates since Jan. 1. In every instance the advances are declared to be necessary because of increased cost of fuel, labor and materials. In a number of cases objections have been filed and hearings held. In the same period there have been notices of increases filed by 24 gas companies, while 20 telephone companies, most of them rural lines doing a purely local business, have given notice of advances in rates.

Stevens Institute Commencement—As many members of the senior class have been pursuing an accelerated schedule since Nov. 21, 1917, the graduating exercises this year will be advanced from June 11 to Apr. 2, as follows: Saturday, Mar. 30, 8 p.m., alumni smoker; Sunday, Mar. 31, 7:45 p.m., baccalaureate sermon. Tuesday, Apr. 2, 10:30 a.m., forty-sixth annual commencement in the auditorium; 1 p.m., President and Mrs. Humphreys' reception to the graduating class, trustees, faculty, alumni, undergraduates and friends at Castle Stevens; 3:30 p.m., review of Stevens Battalion under command of Francis G. Hubbard, First Lieutenant, 71st Infantry, N. Y. G., drillmaster, by President Humphreys and graduating class.

Business Items

The Wilson-Snyder Manufacturing Co., of Pittsburgh, Penn., has opened an office in Cleveland, Ohio, at 511 Citizens Bldg., with H. W. Van Cleve, of the Pittsburgh office, in charge as district manager.

The D. Connelly Boiler Co., of Cleveland, has awarded contracts for an addition to its main boiler shop. The addition will be 140 x 80 ft. of steel construction and glass. This company is installing a set of plate-bending rolls which are said to exceed in length and capacity any similar machine in any boiler-manufacturing plant in America.

The Dingle-Clark Co. has been organized with offices at 536 Engineers Bldg., Cleveland, Ohio. This corporation will handle a complete line of motors, transformers, controllers, turbo-gears and is in a position to install electrical equipment for any size plant. Howard Dingle and W. W. Clark were, up to Feb. 1, respectively district manager and assistant manager of the Crocker-Wheeler Co. in Cleveland. Both are well known in Ohio electrical circles by reason of their ten-year connection in this territory.

William T. Price resigned as manager and chief engineer of the De La Vergne Machine Co.'s oil-engine department recently to become president of the P-R Engine Co., of New York, and second vice president of the Rathbun-Jones Engineering Co., of Toledo, which will undertake the sale and manufacture respectively of Price-Rathbun stationary and marine oil engines built in accordance with a new principle of fuel injection developed by Mr. Price during the past several years. The P-R Engine Co. has its main office at 110 West 40th St., New York, 'and branch offices in Philadelphia, Baltimore and Toledo.

NEW CONSTRUCTION

Proposed Work

N. J., Jersey City—The Hudson County Boulevard Commissioners will receive bids until April 3 for equipment for the lighting system of the Hudson County Boulevard. E. Cahill, Pres.

N. J., Pitman—The Electric Co. of New Jersey has been granted permission by the Board of Public Utilities, to issue $197,000 bonds; the proceeds will be used to build additions and make improvements to its plant. W. P. Mercer, Mgr.

Penn., Clifton Heights—The Kent Manufacturing Co. has had plans prepared for the erection of a power plant and boiler house. Estimated cost, $50,000. F. E. Hahn, Arch., 1112 Chestnut St., Philadelphia, is receiving bids for the construction. Noted Jan. 29.

Penn., Waynesboro—The Greencastle and Waynesboro Ry. Co., Bank Bldg., is having plans prepared for the erection of a 2 story, 40 x 50 ft. substation. Estimated cost, $10,000. H. D. Sefton, Gen. Mgr.

Md., Linthicum—The Consolidated Gas Electric Light and Power Co., Lexington St. Bldg., Baltimore, will soon award the contract for the erection of a 26 x 40 ft. addition to its power station. Estimated cost, $7000. E. D. Edmonton, Baltimore, Gen. Supt.

N. C., Dunn—The General Utility Co. recently incorporated with $100,000 capital stock, plans to build an electric lighting plant. Estimated cost, $25,000.

N. C., Warrenton—The Warrenton Electric Light Co. plans to build a 3 phase, 2200 volt transmission system. J. M. King, Mgr.

Ga., Elberton—City plans to extend its electric lighting system. S. W. Allen, Gen. Supt.

Fla., Daytona—The Daytona Public Service Co. plans to increase its capital stock from $300,000 to $500,000; the proceeds will be used for additions and improvements to its system. R. W. Messmore, Ch. Engr.

La., Shreveport—The Elliott Electric Co. is considering the installation of additional equipment.

Ky., Graham—The W. G. Duncan Coal Co., Greenville, will build a 75 x 100 ft., brick and concrete power house. The work will be done by day labor. C. M. Means, Oliver Bldg., Pittsburgh, Pa., Consult Engr

Ky., Newport—The Newport Rolling Mill Co. has acquired a site here and plans to build 11 additional sheet mills and install new machinery including a 6000 kw. generator set to operate proposed mills. Estimated cost, $500,000. W. A. Andrews, Pres.

Ohio, Middleport—The Staltee-Essex Coal Co. plans to install electrical equipment in its mine. F. Essex, Supt.

Ohio, New Petersburg—Fred Essex plans to install electrical equipment in his mine.

Ill., Charleston—City plans to issue $20,000 bonds to improve its electric lighting and water works systems. Address T. T. Shoemaker.

Ill., Rockford—City election in April to vote on $500,000 bonds for the erection of an electric lighting plant. E. A. Wittergren, City Clerk.

Wis., Reedsburg—City plans to improve its electric lighting plant and install new machinery including electrical generating unit of 250 or 300 kw. directly connected to either uniflow engine or steam turbine. O. W. Burkett, Gen. Supt.

Wis., Thorp—The Thorp Electric Light and Power Co., recently incorporated plans to take over the City electric lighting plant and improve and enlarge same. P. D. Kline, interested.

Iowa, Dysart—The Iowa Ry. and Light Co. plans to install a high tension line from here to Traer. W. G. Dows, Cedar Rapids, Gen. Mgr.

Kan., Colby—City plans to build a transmission line from here to Oakley. C. V. Parrott, City Clerk.

Kan., Gardner—City plans to build an electric lighting plant. Estimated cost, $20,000.

Neb., Carroll—Village voted $9500 bonds to install a lighting system.

Neb., Schuyler—City election April 2 to vote on $40,000 bonds to build an electric lighting plant. E. A. Schmid, Mgr.

Okla., Stillwater—City voted $175,000 bonds for improvements and additions to its electric lighting plant. G. M. Smith, Supt. Noted Mar. 5.

N. M., Gallup—The Town Board plans an election to vote on propostion to build an electric lighting plant. K. H. Myers, Secy.

Wash., Walville—The Central Light and Manufacturing Co. has filed a petition with the Lewis County Commissioners, for authorization to build an electric light and power line from here to Meskill. R. P. Brush, Pe Ell, Supt.

Calif., Bakersfield—The Mt. Whitney Power Co. of Bakersfield, plans to spend $108,562 to improve and enlarge its hydroelectric generating plants and $216,937 to extend distributing lines in Tulare, Kern and Kings Counties. E. R. Davis, 624 Pacific Electric Bldg., Los Angeles, Mgr.

Ont., Armagh—The Armagh Electric Co. receives bids in April for electrical equipment for power development. Estimated cost, $40,000.

Ont., Cornwall—The Cedar Rapids Transmission Co. has had plans prepared for the erection of a 110,000 volt station.

Ont., London—The City will appropriate $25,000 for extensions to its electric lighting plant.

Ont., Rideau—The Hudro Electric Commission plans to purchase High Falls on the Mississippi River and build a generating station on same.

B. C., South Wellington—The Canadian Collieries are in the market for boilers and air compressors to install in the mines.

CONTRACTS AWARDED

N. J., Hoboken—The Board of Education has awarded the contract for installing electrical fixtures and lighting system in Public School No. 3, to W. Coleman, 29 Willow Court, Jersey City. Estimated cost, $15,000.

N. J., Jersey City—The Board of Education has awarded the contract for installing electrical fixtures and lighting system in Lincoln High School on Harrison Ave., to W. Coleman, 29 Willow Court. Estimated cost, $21,000.

N. J., Perth Amboy—The American Smelting and Refining Co. has awarded the contract for a 1 story, 60 x 70 ft. addition to its power house to be erected on Maurer St., to I. Crouse, 495 State St. Noted Oct 23.

Penn., Philadelphia (Kensington)—L. S. Leberman has awarded the contract for a 1 story, 30 x 40 ft. power house addition and a new boiler house, to Conneen Constr. Co., 1737 Filbert St. Noted Feb. 26.

D. C., Wash.—The U. S. Government has awarded the contract for electric lighting system in Anacostia, to the G. E. Engineering Co., 417 Canal St., New York City. Estimated cost, $10,535.

Tenn., Hadleys Bend—The U. S. Government has awarded the contract for furnishing electrical equipment for the proposed power plant, to the West Electric Co. Estimated cost, $5,000,000.

Ohio, Cleveland—City has awarded the contract for an addition to its electric lighting plant on East 53rd St., to Kelley Demarest Constr. Co., 418 American Trust Bldg. Estimated cost, $25,000. City is constantly purchasing machinery and equipment and will soon be in the market for all kinds of boilers, generators, switchboards and equipment. W. E. Davis, Ch. Engr.

Mich., River Rouge—The Ford Motor Co. has awarded the contract for a 1 story, 10 x 60 ft. transformer house to be erected on Dix Rd. and River Rouge, to H. G. Christman Co., Stevens Bldg., Detroit.

Ill., Great Lakes—The U. S. Government has awarded the contract for an addition to the overhead distribution and lighting system at the Naval Training Station, to Paxchen Bros., 111 West Washington St., Chicago. Estimated cost, $7830.

Mo., Carthage—The Polak Steel Co., Cincinnati, Ohio, has awarded the contract for an addition to its power plant here, to M. Marcus Building Co., 2023 Reading St., Cincinnati, Ohio.

Wash., Puget Sound (Bremerton P. O.)—The U. S. Government has awarded the contract for a telephone and transmission line, to Nepage & McKenny, Armour Bldg., Seattle Estimated cost, $8950.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1] Mar. 21, 1918	Individual[1] Mar. 21, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1] Mar. 21, 1918	Individual[1] Mar. 21, 1918
Pea	$5.05	$5.80
Buckwheat	4.30—5.00	5.50—5.80
Barley	3.25—3.50	4.00—4.25
Rice	3.75—3.95	4.50—4.80
Boiler	3.50—3.75	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Mar. 21, 1918	One Yr. Ago	Mar. 21, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties Mar. 21, 1918	Mt. Olive & Staunton Mar. 21, 1918	Standard Mar. 21, 1918
6-in. lump	$2.65-2.80	$2.65-2.80	$2.65-2.80
2-in.-lump	2.65-2.80	2.65-2.80	2.65-2.80
Steam egg	2.65-2.80	2.65-2.80	2.65-2.80
Mine-run	2.40-2.55	2.40-2.55	2.40-2.55
No. 1 nut	2.65-2.80	2.65-2.80	2.65-2.80
2-in. screen	2.15-2.30	2.15-2.30	2.50-2.65
No. 5 washed	2.15-2.30	2.15-2.30	2.50-2.65

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

Underground Steam Mains

By CHARLES L. HUBBARD

While the construction details of underground mains are much the same as for any other piping of large size, the fact that they are less accessible in case of repairs makes it necessary to use extra care in their installation. Furthermore, the greater length of run as compared with ordinary power-plant or heating work makes the matter of expansion one of much importance, which calls for special provision and anchors.

THE method of making the joints will depend upon the pressure and temperature carried on the system. For heating, both by steam and water, the lengths of pipe are commonly put together with screwed couplings, placing flanges at sufficiently frequent intervals to facilitate the removal of sections should occasion require, but, so far as possible, advantage should be taken of the flanged joints which must be put in for other purposes and in this way reduce the cost of installation. These flanged joints will occur at bends, take-offs to buildings, expansion joints and anchors. For the low pressures carried on heating work, the plain flange with a good form of flexible packing gives satisfactory results and allows of a section of pipe being easily removed, which is a more difficult matter with a recessed flange on heavy piping. A gasket of "soft" packing will make up for any small inaccuracies in the alignment of the pipe and is not so likely to permit a leak should the line settle slightly. Corrugated copper gaskets have been used with satisfactory results. If a recessed joint is to be used, the male-and-female type, shown in Fig. 1, is preferable to the tongue-and-groove flange, being easier to pack when in place. The depth of recess is made just sufficient to hold the packing in place, varying from $\frac{1}{16}$ to $\frac{1}{8}$ in., according to the size of pipe. There is danger of leaks developing where the flanges are joined to the ends of the pipe—that is, when the pipe does not extend through the flange—because there may be sand holes in the casting, imperfect threads, etc.; but this is guarded against in various ways, one of the simplest and most satisfactory being by threading the pipe with a full taper, then screwing the flange on by power until the end of the pipe projects through about $\frac{1}{16}$ in., then facing off in a lathe. Another method is to round off the inner edge of the flange and expand or peen the end of pipe into it, as in Fig. 2.

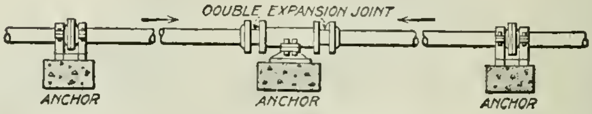
DOUBLE SLIP-JOINT
FIG. 5



DOUBLE SLIP-JOINT WITH ANCHORS
FIG. 6

FIGS 5 AND 6. DOUBLE SLIP-JOINT AND ITS LOCATION IN A LINE

For lines carrying high pressure, and especially highly superheated steam, more care must be taken in the construction of the joints. While there are many types of higher-pressure flanges in use, some form of the Vanstone joint is probably employed more frequently than any other. The principle of this joint is illustrated in Fig. 3 and consists essentially of flanging the ends of the pipe and drawing them together by means of a pair of loose flanges or hubs slipped over the pipe, which act as a clamp. In order to give sufficient strength, the flanged ends of the pipe must be thickened either by upsetting or turning over a flap to get the extra thickness. As it is difficult to get a perfect weld in the latter case, it seems best to first upset the end of the pipe to obtain the necessary thickness, which should be at least equal to the normal pipe walls after machining on both sides.

The form shown in Fig. 4, in which the stock is somewhat thinner at *A* than the pipe wall and slightly thicker at *B*, has given satisfactory results. Finishing the flange or lap is of much importance, and in general it should be machined on both sides to get a tight and durable joint, although in some cases only the face is finished when the back is accurately formed and the scale carefully removed. Tests made on joints of this construction show that the laps will hold considerably more pressure than the bolts, and with specially designed flanges and bolts it has been shown that the pipe will burst before the joint will give way. To make a lasting joint, the pipe flange should fit snugly in the hub of the outer flange in order to give it the proper support.

For pressures above 150 lb. the outer flanges should be of the "high-hub" type, made of rolled, forged or cast steel. While a joint of this type may be made tight without a gasket, by grinding, it is not usually advisable in case of inaccessible mains, because a ground joint is expensive and, even if properly made, may become loosened by the tremendous forces of expansion and contraction. It is therefore recommended that the bearing faces be given a fine tool finish and be provided with a gasket suitable to the pressure and temperature carried. The ordinary corrugated copper gasket has given satisfactory service for saturated steam, but does not seem to be good for superheated steam, owing to a tendency to pit out in some part of the flange from some undetermined cause. In place of copper soft Swedish steel coated with "Smooth-on" cement has been satisfactorily used. Gaskets made up of copper on bronze surrounded with asbestos have also been made use of.

The life of the gasket depends largely upon the method of pulling up the bolts. If the joint is first drawn up on one side and then on the other, there is almost certain to be trouble with the gasket, but instead of this procedure the bolts should be taken up gradually and evenly all around the flange.

The welded joint is made use of in two ways—either by welding heavy flanges to the ends of the pipe and bolting them together or by uniting the ends of the pipe without flanges. Welded flanges are used where the piping is to be removable or where it is to be joined to a fitting, but joints of this kind are more expensive than the Vanstone type because all finishing must be done on heavy sections of piping, instead of a portion of it being on small individual flanges that are easily handled. Welding the ends of the lengths of pipe, without the use of flanges, is accomplished by means of the oxyacetylene torch or the thermit welder and is successfully employed in laying lines of underground piping for water, steam and high-pressure gas. While the work may be done with the oxyacetylene torch in any position, the best results are obtained when the pipe is rotated so as to do all the welding from the top.

A committee of the National District Heating Association, in 1915, investigated the matter of pipe welding and reported the cost to be from 25 to 50 per cent. less than for screw couplings, depending upon whether the work was done on the bank or in the trench. The cost per joint at that time, for labor and materials for work done on the bank, was estimated as follows: 4-in., \$0.44; 6-in., \$0.57; 8-in., \$1.06; 12-in., \$1.57; 16-in., \$2.21. The cost for welding in the trench was estimated at twice the foregoing. If it is necessary to remove a section at any subsequent time, it is easily cut out by means of the oxyacetylene flame and a new piece of piping welded in by the same means.

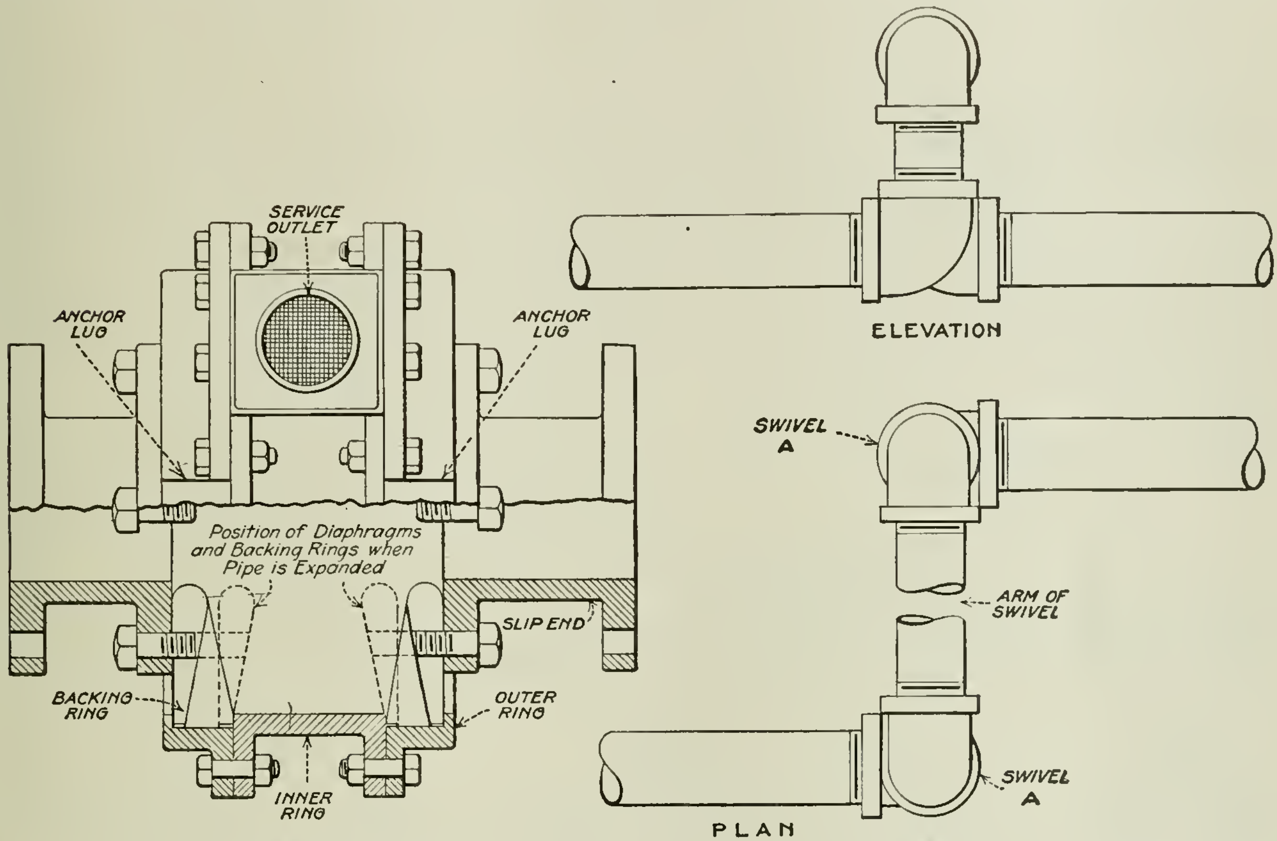
The expansion of wrought-iron and steel pipe under different conditions may be determined by the formula,

$$l = 0.00009(T_1 - T_2)L$$

in which

l = Increase of length, in inches;
T_1 = Temperature of steam in pipe;
T_2 = The lowest temperature to which the pipe is to be subjected;
L = Original length of pipe in feet.

The factor 0.00009 is obtained by multiplying the

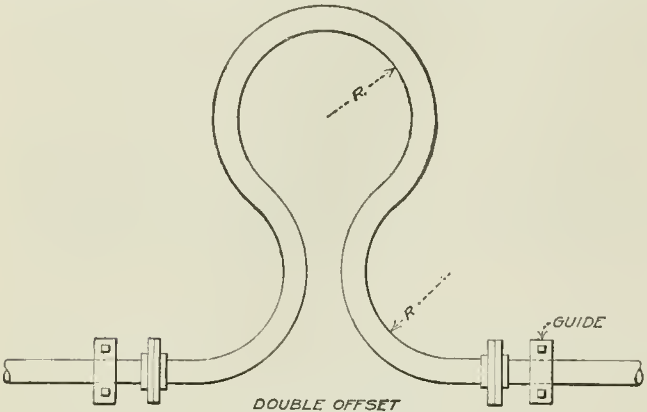


VARIATOR OR DIAPHRAGM EXPANSION JOINT
FIG. 7

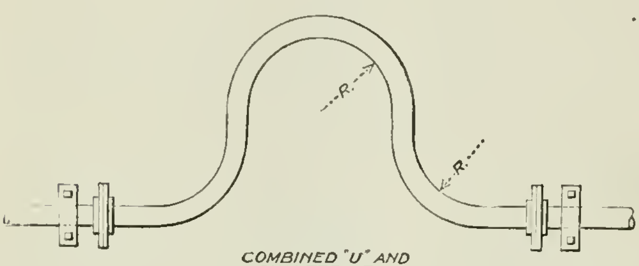
DETAIL OF SWIVEL JOINT
FIG. 8

FIGS. 7 AND 8. TWO FORMS OF EXPANSION JOINTS IN GENERAL USE coefficient of expansion, 0.0000075, by 12, in order to reduce the length L to feet, which puts the formula in more convenient form for general use.

Example: A main 1000 ft. long was fitted at a temperature of 60 deg., the lowest considered, and carries steam at 150 lb. pressure and 100 deg. superheat. What will be the increase in length due to expansion?



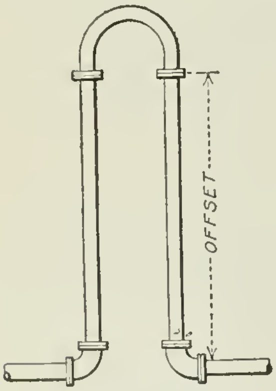
DOUBLE OFFSET EXPANSION BEND
FIG. 9



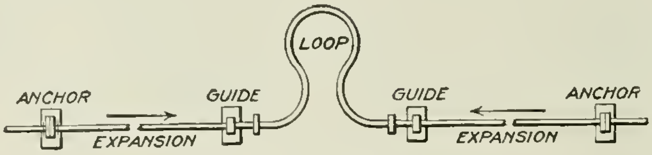
COMBINED "U" AND QUARTER BEND
FIG. 10

FIGS. 9 AND 10. STANDARD FORMS OF EXPANSION BENDS

Here, $T_1 = 366 + 100 = 466$, $T_2 = 60$ and L 1000. Substituting in the formula gives $l = 0.00009(466 - 60)1000 = 36.5$ in., or practically 3 ft. This shows the importance of providing means for taking care of the variation in length so as to avoid throwing undue strain on pipe and fittings. In low-pressure steam and water heating the expansion is much less, owing to lower working temperature. In work of this kind the increase in length will not usually exceed 1.5 in. per 100 ft. of run.



OFFSET EXPANSION LOOP
FIG. 11



Expansion in Opposite Directions

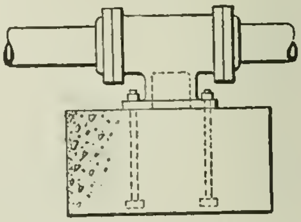
BAR AND STRAP ANCHOR
PLAN
FIG. 14



TEE ANCHOR
FIG. 15

FIGS. 11 TO 15. LINE CONSTRUCTION WITH EXPANSION LOOPS AND ANCHORS

There are three methods commonly employed for taking care of the expansion in long runs of piping—expansion joints, which include slip joints and variators; swivel joints; and loops. The objection to slip joints is the difficulty in keeping them in working adjustment, for if the gland is drawn up too tightly the joint will not slip, and on the other hand, if too loosely adjusted leakage will take place. In order to get the best results, the pipe line must be securely anchored at suitable points and also properly supported upon either side of the joint to prevent sagging and binding.

A simple way of combining all of these requirements in a single fitting is shown in Fig. 5, which illustrates double-slip joint, outlet and anchor. The method of installing this in the line and its relation to other anchors is shown in Fig. 6. Joints of this type should be so spaced that the maximum slippage will not exceed five or six inches, which in the case of low-pressure steam or hot-water heating will mean every 300 or 400 ft. A typical expansion joint of the "variator," or diaphragm, type is shown in Fig. 7. In this case the expansion and contraction are taken care of by a pair of flexible copper diaphragms of a special form. Joints of this design avoid the use of stuffing-boxes and all adjustments, thus making them especially adapted to underground work. It is, however, a patented device and must therefore be obtained from the manufacturers.

The swivel joint, or expansion loop, is also made use of in places where suitable. The first of these is usually adopted where long-radius bends are not practicable on account of lack of space and where screwed fittings or joints of the Vanstone type are used. A diagram of this arrangement is shown in plan and elevation in Fig. 8, which illustrates how any lengthening or shortening of the line is taken up by a slight turning or swivel movement at the flanges at points A. When there is ample space, long-radius bends are preferable to any other method, especially for high-pressure work. In this case all movement of the pipe is taken up by the elasticity of the metal, thereby doing away with any movement at joints. A typical expansion loop is shown in Fig. 9, and as the pipe itself is under an enormous strain, it is evident that the loop must be carefully proportioned in order not to overtax any part of it.

Table I, made up from curves published some time ago in the *Electrical World*, gives the maximum allowable expansion for different sizes of pipe with varying radii of bend of the general form shown in Fig. 9.

For example, a loop of the form shown in Fig. 9, made of 8-in. pipe and having bends with a radius of 70 in., will safely care for 8 in. of expansion. When the loop is of the form shown in Fig. 10, take 80 per cent. of the expansion given in Table I for the same pipe size and radius of bend.

TABLE I ALLOWABLE EXPANSION, IN INCHES

Diameter of Pipe, Inches	Mean Radius of Bend (R Fig 9) 30	40	50	60	70	80	100
3	3	6	9	13	18		
4	2.5	4	7	10	14	18	
5		3	6	8	11	15	23
6			5	7	10	12	20
8				6	8	10	15
10				4	6	8	12
12				3	4.5	6	10
14					4	5.5	8

These figures are based on the strain in the pipe, and any strain at the flange joints other than that parallel with the axis of the line should be guarded against by guides, as indicated.

Sometimes the expansion loop is made up of a pipe bend and fittings, as in Fig. 11, in which case Table II may be used to give the required length of offset for different amounts of expansion and different sizes of pipe. These figures take into account the strain on the fitting as well as on the pipe and are therefore somewhat higher than would be required if the fiber strain of the pipe alone were considered.

The inner radius of the bend at the end of the loop should never be less than five diameters of the pipe, and a length of straight pipe equal to two or three diameters should be provided at each end for handling in the process of bending. In order to distribute the expansion evenly between the different joints or loops, it is necessary to anchor the pipe at regular intervals. The method of placing the anchors for a double-slip expansion joint is shown in Fig. 6, in which case the expansion is toward the joint from either side, as indicated by the arrows. This arrangement is also applicable to an expansion loop, as in Fig. 12. When it is desired to use shorter loops, they may be placed close together and the expansion made to take place continuously in one direction, as in Fig. 13, which shows the arrangement of guides and anchors with reference to the loop. The layouts shown are for long lines of pipe. It frequently happens in practice that sufficient offsets and changes in direction are necessary to reach the different buildings to furnish a considerable part of the flexibility required without the use of special joints. Conditions of this kind should be fully taken advantage of in order to simplify the construction and reduce the cost of installation.

TABLE II. LENGTH OF STRAIGHT PIPE IN OFFSET, IN FEET (Fig. 11)

Expansion in Inches	Diameter of Pipe, Inches 3	4	5	6	8	10	12	14
1	7	8	9	10	11	12	13	14
2	9	11	12	13	15	16	18	19
3	11	13	15	16	18	20	22	24
4	13	15	17	19	21	24	25	28
5	15	17	19	21	24	27	29	32
6	17	19	20	23	26	29	32	35
7	18	20	22	24	28	31	34	37
8	20	22	24	26	30	33	36	40

Various methods are employed for anchoring a pipe line, depending upon local conditions. A simple form that may be applied at any flanged joint or offtake fitting is shown in Fig. 14, and is self-explanatory. Another, formed of a tee fitting with the side outlet closed, is illustrated in Fig. 15. This requires a special foundation built into the conduit to which the flange of the tee is bolted. All expansion joints of the slip or "variator" type which have moving parts should be placed in manhole chambers where they are readily accessible. Expansion loops should have ample room to expand in the conduits or chambers without coming in contact with the side walls or other piping. The method of support will depend largely upon whether the pipes are carried through tunnels or conduits of comparatively small size and is best taken up in connection with tunnel and conduit construction.

Boiler Explosion at Providence, R. I.

By H. S. Knowlton

A sixty-inch horizontal return-tubular boiler at the Mt. Pleasant Wet Wash Laundry, Providence, R. I., exploded at 6:40 a.m. Monday, Mar. 4, killing three persons, seriously injuring four others and completely wrecking the establishment. The boiler was being fired by one of the proprietors, who was killed. It was inspected July 15, 1917, by E. W. Farmer, city boiler inspector of Providence, and was reported then in first-class condition. Business growth at the laundry led to the recent purchase of two large washers, which were being placed in service for the first time on the morning of the explosion.

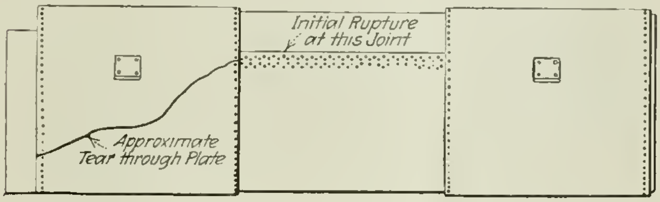


FIG. 1. WHERE INITIAL RUPTURE OCCURRED AND APPROXIMATE PATH OF TEAR THROUGH FIRST SHEET

The boiler contained sixty 3-in. tubes 16 ft. long and was hand-fired. It supplied steam to a small single-cylinder engine and to the various steam-heated machinery housed in the laundry, a 50 x 60-ft. one-story wooden structure. As the fireman was instantly killed, it is impossible to determine with exactness the condition immediately preceding the explosion, but one of the partners of the concern, who passed through the boiler room at 4:30 a.m., states that at that time the steam gage showed a pressure of 55 lb. and that about four inches of water was showing in the gage-glass.

Examination of the boiler after the disaster disclosed no apparent structural defects. The boiler sheets had no indication of having been burned or of crystallization where the fracture occurred. The explosion tore the boiler in two. The rear sheet and tube head, Fig. 2, were thrown backward to a point just behind the original location of the boiler. The other section, comprising the center and front sheet, Fig. 3, opened up, the shell being torn away from the tube sheet and flattened out in an irregular plate. Many of the tubes were blown out and scattered about the neighborhood for distances up to 600 ft., but the damage was slight excepting in the laundry itself.

From the appearance of the wreckage it is deduced that the initial failure occurred in the longitudinal seam of the center sheet and extended to the girth seam between the first and second sheets. From this point the first sheet was torn diagonally through the solid metal to the front head about as shown in Fig. 1. The opening up of the center sheet tore through the rivet holes on the girth seam, as shown in Fig. 2. A portion of the sheet of the rear section was torn instead of the rupture following the rivet holes of the girth seam.

FIG. 2. REAR SHEET OF THE EXPLODED BOILER

The boiler was of the single butt-strap double-riveted design, the rivets being $\frac{3}{4}$ in. in diameter, spaced 3 in. apart on centers and staggered in rows 2 in. apart. The shell plate was $\frac{5}{16}$ in. thick. In the rear section six of the tubes remained attached to the tube sheet, and although some of these were flattened out and bent, no signs of fracture could be seen. There was a slight pitting on the front tube sheet, and a little pitting was noticed on the side of the larger sheet fragment.

Most of the braces, which were $1\frac{1}{4}$ in. diameter, remained in place in the rear section of the boiler, the rivets of which held with the exception of three at the girth seam, which were in a longitudinal joint, these three being sheared off.

The boiler had not been operated for about 48 hours prior to opening the laundry on the morning of the explosion, but there had been a pressure of about 20 lb. throughout the night. The boiler was operated at 75 lb. pressure; it was about six years old and was allowed a maximum pressure of 100 lb. The safety valve was of the ball-and-lever type and was connected to the boiler by a cast-iron nozzle of light construction. The safety valve had not lifted from one year's end to the other, and on the night before the explosion the partner who was killed moved the ball out to the end of the lever, which put the blowing-off point to 120 lb. instead of 100, allowed on the inspection certificate, and 75 lb., the normal operating pressure.

Summing up, the evidence is that the boiler operator was not experienced; the single butt-strap joint on the longitudinal seam was of poor construction; the violence of the explosion indicates that there was plenty of water and a high steam pressure. A sticking safety valve, together with the weight moved to the extreme end of the lever and a hot fire in the furnace, left to take care of itself (as was done while the engine and other machinery was being got ready for starting up) are the probable causes for the explosion.

FIG. 3. FRONT TUBE SHEET AND FIRST TWO SHELL SHEETS

Hydro-Electric Power Development in Australia and New Zealand

BY LUDWIG SCHMIDT

An account of the present state of hydro-electric development in Australia and New Zealand, the proposed extensions and new enterprises, and a brief outline of the legal conditions under which the water-power resources are made available.

THE utilization of the water-power resources of the Australian continent, if not exactly a monopoly of the government, is at least a prerogative secured to the nation by a series of laws passed during the last twenty or thirty years. As these laws are similar, it will be sufficient to give the principles of the law of the State of Victoria, which was passed in 1896. According to this law, the state reserves to itself the right to generate electrical power including that drawn from natural sources. This right can be delegated to others under a special license, which, however, in the case of a person or a private corporation, cannot run longer than thirty years. At the expiration of the term the license may be renewed at the option of the state, under modified conditions which apply mostly to the optional powers of the municipalities or the state to acquire, when desired, the property of the licensee for the purpose of municipal or state operation. No electrical enterprise can be undertaken without the issuance of a special order or permit. This stipulation, however, does not apply to private undertakings, such as installations made in factories and for similar purposes. The carrying of overhead lines requires special permission by the local or government authorities, as the case may be. High-pressure transmission lines are subject to special control. The government retains the right to review the rates charged, and no enterprise may discriminate against any consumer as to distribution or charges.

DISTRIBUTION OF OPERATING LICENSES IN VICTORIA

Under this law 107 licenses were issued in Victoria from 1896 to 1914, of which 57 allowed the operation of municipal enterprises, 49 applied to private and corporate enterprises and one was given to the government. As to the influence of the laws governing transmission of power, the result has been a preponderance in favor of overhead transmission, which extended during 1914 over 3233 miles, while there were in existence only 80 miles of underground cables.

Electrical enterprise and power development had been extremely active in Australia before the war, but since that time progress has been slower, apparently because of the general contraction of capital. Lack of suitable shipping facilities made it difficult for Australia to dispose of its foodstuffs and raw materials in the world's market. The result was a general desire to save on the part of municipalities and the government, both of which are responsible for the extension of electric enterprise. On the other hand, the causes that led to a decline in expansion have added to a general activity in the industry itself. With Australia receiving less goods from abroad, the home industry was compelled to make up the loss. New machinery was introduced, and with the machinery new manufacturing methods, which resulted in a greater consumption of electric power. Also, the electrochemical industry, which was much benefited by the war, increased the demand on the power resources of the country.

The yearly report of the Melbourne Electrical Supply Co. is generally regarded as an index of the state of the electrical industry of the Dominion. The following figures, therefore, are of interest: During the year 1915 to 1916 this company had an increase of 20 per cent. in the number of consumers. The power supply rose 15 per cent., the total connections 22 per cent., and the number of units sold 36 per cent. above that of the year before. The gross revenue was 24 per cent. higher than that of the preceding year.

Similar indications of great prosperity in the electrical industry of Australia may be found in the reports of many other undertakings; but the character of the electrical materials imported shows clearly the direction the electrical business has taken during recent years. During the years 1915 and 1916, for instance, the State of New South Wales received from the United States the following electrical machines and supplies:

	1915	1916
Dynamos	$317,252	$324,031
Switches	92,648	50,110
Heating and cooking apparatus	9,378	9,678
Electroliers	18,361	27,115
Regulating, starting, and controlling apparatus	150,715	96,000
Telephones	180,303	305,319
Accumulators	47,269	13,880
Arc lamps	21,544	15,041
Cables	15,612	28,934
Miscellaneous	1,976	26,969

It will be noticed that the demand has run rather in favor of material for extension purposes than materials for new installations.

In the meantime, however, interest in future electrical development in Australia is far from waning. Good progress has been made in charting and developing the existing natural power resources. In this respect Tasmania has been especially active. Theoretically the Island of Tasmania seems to offer great possibilities for hydro-electric development, but in practice the situation is not quite so favorable. The many small and large rivers which form important falls are not water carriers during the whole year. They lose much of their force during the dry season, and successful hydro-electric development becomes possible only where the flow of the river can be supplemented by the use of artificial or natural reservoirs. Such locations are few on the island, and where they exist they are not situated within easy access of the centers that would be most benefited by them. Even the big natural reservoir which is now used for hydro-electric power generation on a large scale is far removed from its principal consumer, the City of Hobart and the surrounding district.

The so-called Great Lake of Tasmania lies in the center of the island at an altitude of 3350 ft. above sea level. It has an area of 42 square miles and draws its water from a watershed covering 200 square miles or more. During at least six months of the year this region has a comparatively heavy fall of rain, which, if retained, guarantees to the rivers flowing out of the lake a sufficient surplus of water to eliminate the danger of their becoming useless for power generation during the dry months. Here, with the help of a dam conserving the waters of the lake, is in operation the government hydro-electric plant, which serves Hobart and other cities of Tasmania with electric light and power. The dam is run across the southern end of the Great Lake, and the waters are led by the existing river bed to a second reservoir from which pipe lines feed the turbines.

Government Assists Development in Tasmania

The Great Lake region is not easily accessible, and much time, labor and money were lost in transporting materials and machinery to the building grounds. So it happened that the capital provided by the promoters proved to be insufficient, and the work was in danger of being discontinued, as it was impossible at the time to get additional capital. So the government of Tasmania, unwilling to let lapse a project which, when completed, would benefit the whole country materially, stepped in and undertook to finish the scheme under an agreement with the former owners.

After the government took hold, the work progressed very rapidly. The station finally was opened during 1916 with an initial development of 10,000 hp. of the 100,000 hp. which is expected to be available. The result of the opening has been that most of the cities in proximity to the station either have given up their own power enterprises or have connected their stations with the government scheme.

The City of Hobart has entered into an agreement which secures to the city at least 1,500,000 units per annum, to be used for municipal and private purposes. The city pays a minimum price for the power consumed and undertakes to do everything in its power to increase the sale and use of electrical power within its limits. The government reserves the right to deal directly with consumers that buy more than 500 hp. The government also bought the existing generating plant of the city, to be used in an emergency, and it is stipulated that the city shall have the first call on the power generated in this station, should the occasion arise.

Electric Power for Mining Companies

The government also has made power-supply agreements with several of the large mining and electrometallurgical enterprises that operate in the island, such as Amalgamated Zinc, Ltd., and the Mount Lyell Co. Beginning with the first of January of the present year, the government agrees to supply Amalgamated Zinc with 4000 hp., and within two years that company agrees to take 26,000 additional horsepower at a price of $300,000 per year for the 30,000 hp. It also has a call for 20,000 hp., which need not be taken from the Great Lake development. Under a similar agreement the Mount Lyell Co. will receive 50,000 hp. The extension of the plant for the purpose of supplying these additional demands is already under way, and during the spring of last year $855,000 was voted by the Tasmanian government for the further development of the site.

There has been some dissatisfaction among Tasmanian manufacturers over the government's action in distributing the vast power resources of the Great Lake to big industrial enterprises, and so there has been an extension of surveys made in the island for other sites likely to be used for power development. As a result the following new developments have been proposed: A development of 10,000 hp. can be obtained on Lake Rolleston, near Zeehan. There are several prospective sites on the Franklin River. The Great Lake region contains, apart from the big development described, a possible development of at least 40,000 hp. on the Derwent River, which would have to be worked in conjunction with the lake. From 40,000 to 50,000 hp. may be obtained on the Arthur Lakes.

In the meantime work has begun on the Mount Lyell development on King River. Here a dam 120 ft. high across a narrow gorge forms a reservoir of 3½ square miles, sufficient to generate 30,000 hp. The water is carried in pipe lines to the power station, which will be operated by the government and will be used principally to furnish current for the electrical treatment of zinc ores.

Hydro-Electric Tendencies in New Zealand

The present tendency of hydro-electric development in New Zealand probably is best characterized by quoting from the report of U. S. Consul Alfred A. Winslow, of Auckland. This report says: "Much preliminary work is being done on proposed public works, such as extensive harbor improvements at several ports, hydro-electric plants and new railway developments on North Island, many new public buildings and extensive road building to open up new sections of the country. The government hydro-electric plant at Lake Coleridge, about 70 miles west of Christchurch, was opened during the year with splendid results for Christchurch and vicinity. The city is now lighted by electricity, the tramcars are operated with power from this source, and many of the industries in and about the city secure their power from this plant, at very low rates in all cases. There is a demand for more current than can be supplied by the present installation of 6000 hp., and it is proposed to put in another unit of equal power. The Minister of Public Works has announced that progress was made on the preliminary work for government hydro-electric development in the North Island and that the work will progress until completed. with a view to developing the scheme as soon as conditions warrant."

These preparations in the meantime have developed rapidly, and they show that a great number of sites will be available for hydro-electric purposes in the island. The most promising are the following: A large development able to produce 120,000 hp. on a 50 per cent. load-factor basis at the Arapuni Gorge, eight miles from Hira Hira. Of this total, 30,000 hp. could be developed at a cost of $6,000,000. This would be sufficient to cover the present demand for power from Auckland and surrounding districts. The most suitable source of power supply for the City of Wellington is the Mangahao River, where approximately 50,000 hp. would be available. If this should not be sufficient, there is another site in the Taranaki district offering good facilities. The Hawkes Bay district, finally, could draw its power supply from Lake Waikaramoana.

The scheme of power development proposed by Evan Parry, the chief electrical engineer of the Public Works Department, is very far-reaching. It not only provides for an early development of the principal sites available, but it contemplates also to link up these sites. This would add materially to the security of the output and would guarantee to the whole North Island a continuous source of cheap power probably not to be found in any other territory of the same extent in the whole world.

The Wellington scheme utilizing the waters of the Mangahao River provides for an interesting engineering feat, as it will be necessary to cut a tunnel through the mountain range separating that river from the Tokomaru River With the help of this tunnel the waters of the latter river will be fed to the Mangahao. The power station will be situated on the Mangahao, within easy reach of the railroad, so that material can be transported to the site without much difficulty. To develop 25,000 hp. in this locality will cost approximately $2,100,000. To this will have to be added the cost of providing the trunk lines and other installation necessary for power distribution to the district, which is estimated at approximately $2,900,000, bringing the cost of the scheme to $5,000,000 in all. Trunk lines will be run from the central generating station to Wellington, Palmerston North, Wanganui, and Masterton as chief distributing centers. The power will be sold to the municipalities in bulk for distribution to small consumers, and the larger consumers will be supplied by the government.

The enterprise shown by the New Zealand government doubtless has been stimulated very much by the great success of the Lake Coleridge development, the opening of which took place during 1916. The Christchurch municipality says in its yearly report that the development has proved an unqualified success, and a governmental report dealing with the same subject points out that the effect of the new power source was evidenced immediately by a great activity in all industries.

The original development of the Lake Coleridge scheme provided for 6000 hp., but during the erection of the plant it became apparent that this would not be sufficient to meet the large demand, and it was finally decided to add another unit of 2000 hp. to the three already existing. During the first year of operation a fifth unit of 4000 hp. was added. The plant earned enough during the first year of operation to pay for its running expenses, and satisfactory progress has been made since then. R. A. Lundquist, the United States Commercial Agent, who recently visited New Zealand, says that the Lake Coleridge power plant ultimately will supply a territory 75 to 100 miles north and south of Christchurch.

The future of the electrical-power situation in New Zealand will depend largely upon the success of the present undertakings. As in Australia, hydro-electric development in New Zealand is a prerogative of the government under a law passed in 1887 and extended in 1908. Under this law there are in operation at present 111 electrical undertakings, 10 of which refer to tramway systems.

The present tendency all over Australia and New Zealand is to make use as much as possible of the hydro-electric powers available in preference to all other kinds of power. The demand, however, has not grown to such an extent that hydro-electric generation can be used to advantage in all locations. The result is that there is still a very extensive demand for steam turbines and engines. The fact that coal can be obtained at a fairly low rate gives steam generation a decided advantage over gas and the internal-combustion oil motor. According to R. A. Lundquist, there will be a demand, as far as New Zealand is concerned, for steam turbines in units of about 500 to 600 hp. for central stations. Below that horsepower steam engines will be favored for the present.

Bonus Plan for Boiler-Plant Operatives

BY HAYLETT O'NEILL

The author proposes a bonus plan whereby the firemen, boiler cleaners and fire cleaners may share in the saving effected by close attention to operation and maintenance of the boiler-room equipment. Numerous charts are given to readily check up performance of the boilers, efficiency being rapidly estimated on CO_2 content of flue gases and temperature of uptake gases.

THE principal argument for a boiler-room bonus plan is that such a system, in stimulating efficiency and thereby resulting in the workman getting part of the money that otherwise would go to the coal dealer, makes employer and employee partners for each other's benefit.

The extraction of heat from fuel to generate steam is a complicated process. Some of the factors of waste and efficiency are inherent by nature in the fuel, atmospheric conditions, etc., while others are dependent upon the design, operation and upkeep of the furnace and boiler. Ordinarily, a plant using modern stoking equipment should get better results than a hand-fired plant. But unfortunately, the elimination of old equipment comes slowly and the object of a bonus must be to obtain the best results with existing apparatus.

Practically every bonus is estimated from one or both of two measurements: (1) Over-all plant efficiency or money cost of steam production; (2) percentage of CO_2 in the flue gas, an index to the efficiency of firing and maintenance of the boiler settings.

To be of value the first system requires regular and accurate analyses of coal fired, weights of coal fired and water evaporated, etc., and while the over-all efficiency obtained is the final test of plant operation, the system by itself is faulty in that there is no fixation of responsibility for savings or losses upon the individuals concerned in the various operations. Such a system is proper when its benefits are applied to the chief engineer or chief executive.

The CO_2 system, where the flue gas is accurately sampled for an entire period and analyzed, gets surprising results in many places; but such a system is faulty in that CO_2 percentage by itself has no relation to the demands on the coal pile. The CO_2 merely measures the degree of air supplied in excess to that theoretically required as a minimum for perfect combustion of a given fuel. Thus, as in Fig. 1, with coal containing about 5 lb. of hydrogen per 100 lb. of combustible, 10 per cent. CO_2 indicates that 23.2 lb. air was supplied per pound of combustible, or 80 per cent. in excess of theoretical requirements.

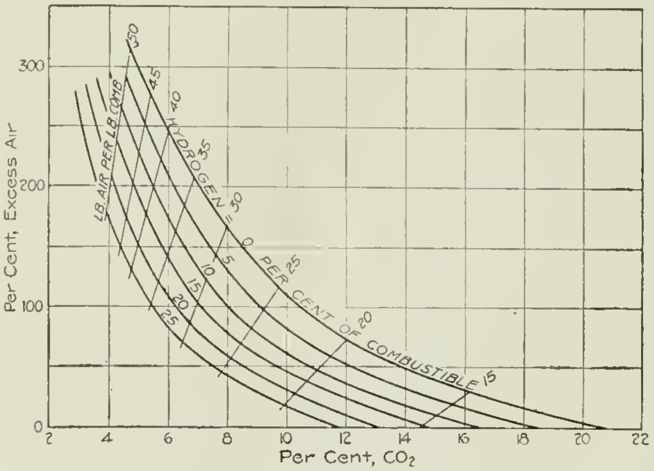

FIG. 1. VARIATION IN EXCESS AIR WITH CO_2 WHEN FUEL IS COMPOSED OF CARBON AND HYDROGEN

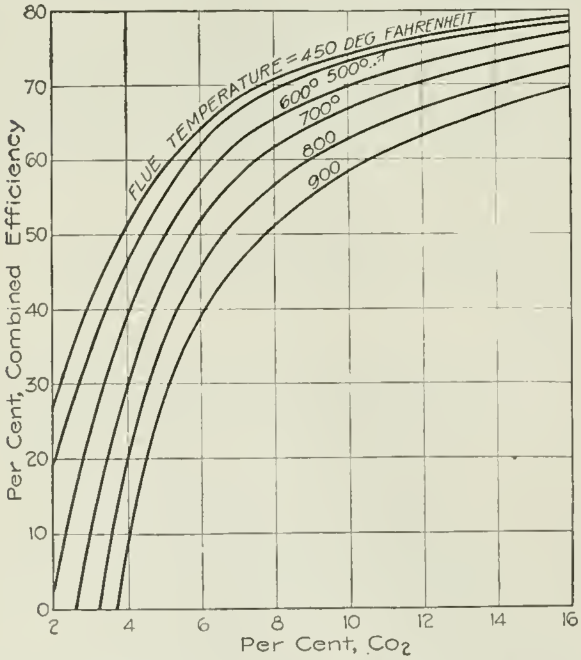

FIG. 2. BOILER EFFICIENCIES ESTIMATED FROM CO_2 AND FLUE TEMPERATURES—EASTERN COALS

By far the greatest operating loss in a boiler and furnace is that loss of heat which escapes in the flue gas, and this heat is measured by the weight of gas and its temperature. Consequently, a knowledge of flue temperature is essential to the measurement of boiler-room losses. These two measurements can be made to accurately indicate the total losses.

Fig. 2 shows the calculated combined boiler and furnace efficiency in terms of CO_2 and flue temperature.

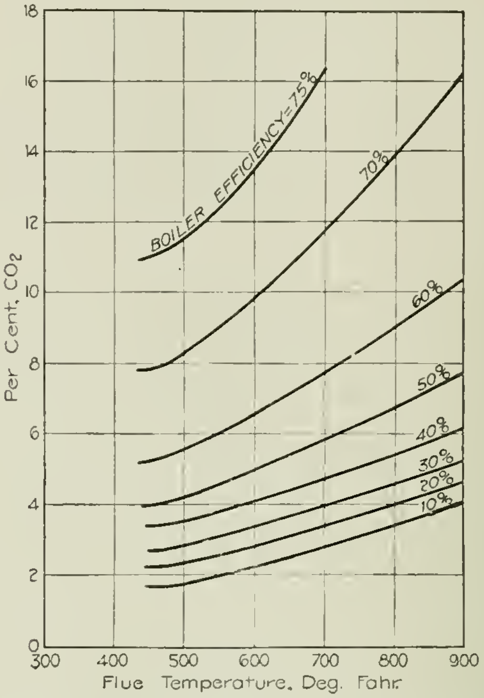

FIG. 3. RELATION BETWEEN CO_2 AND FLUE TEMPERATURES FOR CONSTANT BOILER EFFICIENCY

The values are calculated with certain operating conditions, actually variable, assumed as constant, when the samples of gas and temperatures are accurately taken and averaged over a given period. There will be found a remarkable agreement with actual efficiencies as determined in the usual approved manner. That is to say, if the average CO_2 and flue temperature were respectively 10 per cent. and 600 deg. F., the average combined boiler and furnace efficiency would be 70 per cent. within 1 or 2 per cent. above or below.

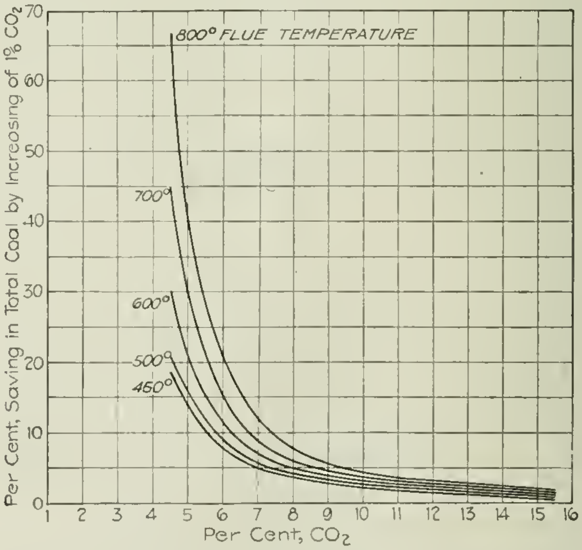

FIG. 4. SAVING IN COAL FOR CONSTANT EVAPORATION BY INCREASING CO_2

Fig. 3 shows more clearly the same values, but with CO_2 and flue temperature plotted against each other for fixed combined boiler and furnace efficiencies: That is, with 8 per cent. CO_2 there would be the same boiler efficiencies as with 14 per cent. CO_2; or 70 per cent., if the flue temperatures were respectively 480 deg. F. and 810 deg. F. If a fireman by careful firing produced 14 per cent. CO_2, and the boiler-cleaning and repair crew allowed the boiler to become dirty, the baffles to deteriorate, etc., the net benefit to the plant would be nil. In fact it is evident from the chart that it is possible to increase the CO_2 percentage and still have a net plant loss. In Fig. 2 a flue temperature of 600 deg. and a CO_2 percentage of 10 per cent. indicate a combined boiler and furnace efficiency of 70 per cent. By increasing the CO_2 to 12 per cent., but permitting the condition of the boiler to become so bad as to result in an 800-deg. flue temperature, the efficiency will fall to about 67 per cent., with a net fuel loss of over 4 per cent.

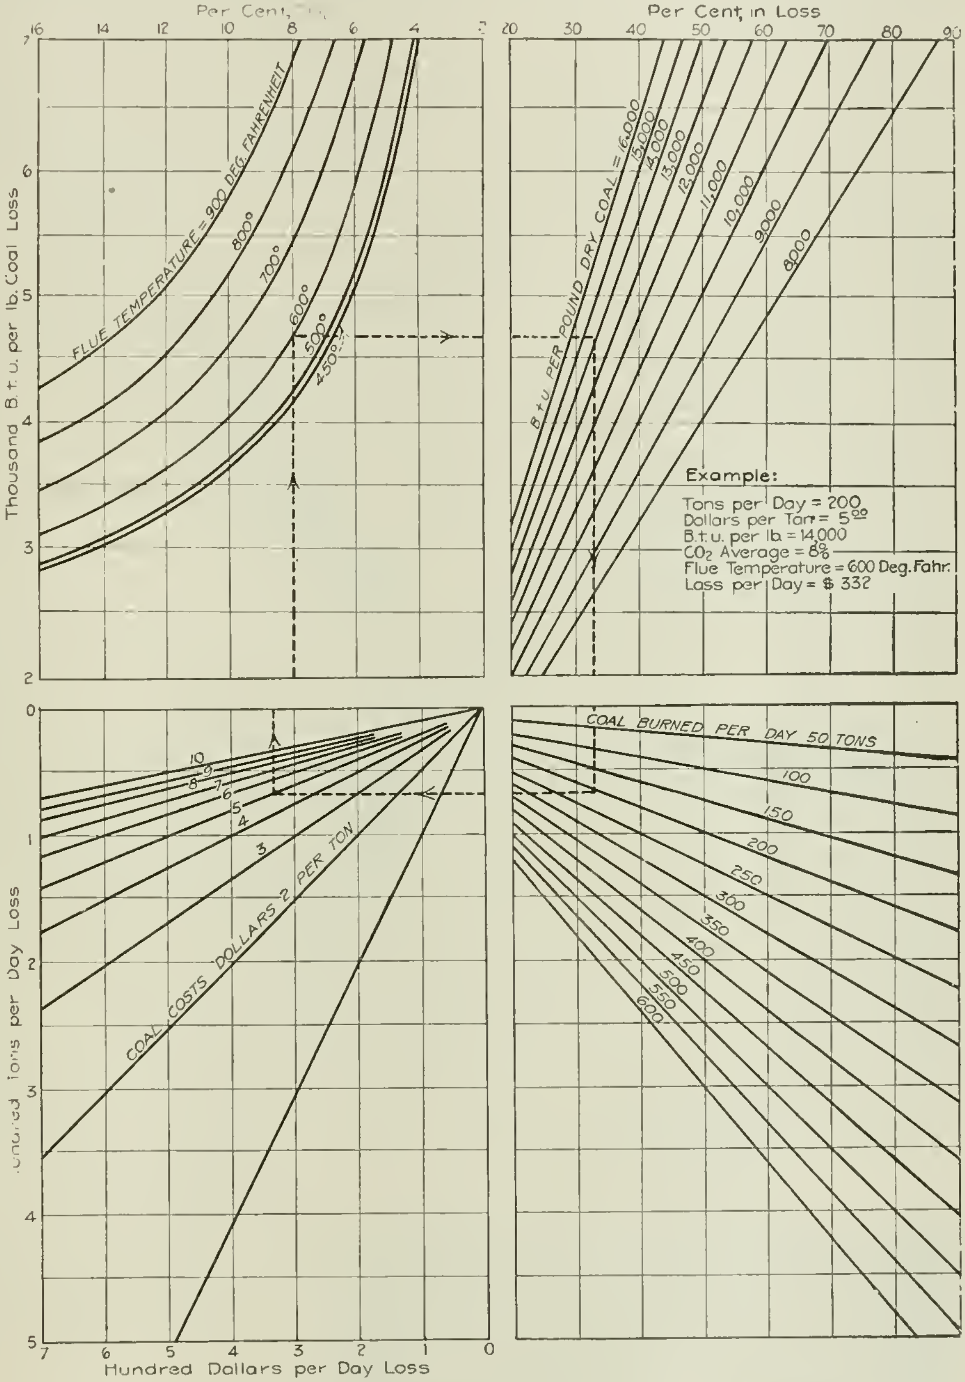

FIG. 5. FUEL LOSSES MEASURED BY CO_2 AND FLUE TEMPERATURES

Nearly all CO_2 bonus systems allow a fixed sum of money for each increase in CO_2 above a standard. The operating results may work out all right in the end, but there is a danger in the workman's not sharing in true proportion to his saving. That is, the percentage of fuel saving per CO_2 percentage increase is variable, depending upon the percentage of CO_2 and flue temperature. A fixed bonus rate results in the workman's receiving less than he is entitled to under certain conditions, and more under other conditions. For a plant run at high rating or with poor heating surface, the importance of high CO_2 percentage is greatest. There is a greater gain from boosting low CO_2 than from boosting high CO_2. That is, in Fig. 4, with 600 deg. flue temperature, a gain in CO_2 from 9 per cent. to 10 per cent. will save 3 per cent. coal, while a gain from 4 per cent. to 5 per cent. will save 20.5 per cent. coal. This explains the almost incredible savings that can be made in a poorly fired plant, with only a slightly increased effort by the management and the workmen. It is easy to make big savings in a poorly operated plant; but the savings become increasingly hard as perfection is approached.

Although there is theoretically a gain in increasing CO_2 up to a point of zero excess air, 18 per cent. to 19 per cent. for soft coal, there is probably no practical gain in going beyond 16 per cent. Engineers are not agreed upon this point because of the difficulty of getting sufficient accurate data, but it may be said that the gain would be next to nothing.

Thus a bonus system based on a fixed payment per percentage increase of CO_2 and planned to give to the workman a reasonable percentage of the savings made by improving poor operation may bring as large bonuses to the workman as the total saving to the plant, when top-notch results are obtained, in which case further improvement results in a loss to the owner.

The proposed bonus scheme is to pay a bonus to each of three classes—firemen, boiler cleaners and fire cleaners—who are respectively responsible for performances measured by CO_2, flue temperature and percentage of combustible in refuse, each of which values determines the bonus. Actually, the three classes may be vested in one man or several, in which case the bonuses are to be calculated in the same way, but payment is to be made according to responsibility. In a one-man plant one man would get three bonuses, etc. Each bonus is to be a fixed percentage of the fuel saving measured by CO_2, flue temperature and percentage combustible in refuse, for results better than those measured by standard CO_2, flue temperature and percentage combustible in refuse. Thus there will always be a fixed ratio between profits of workmen and owner, which is desirable.

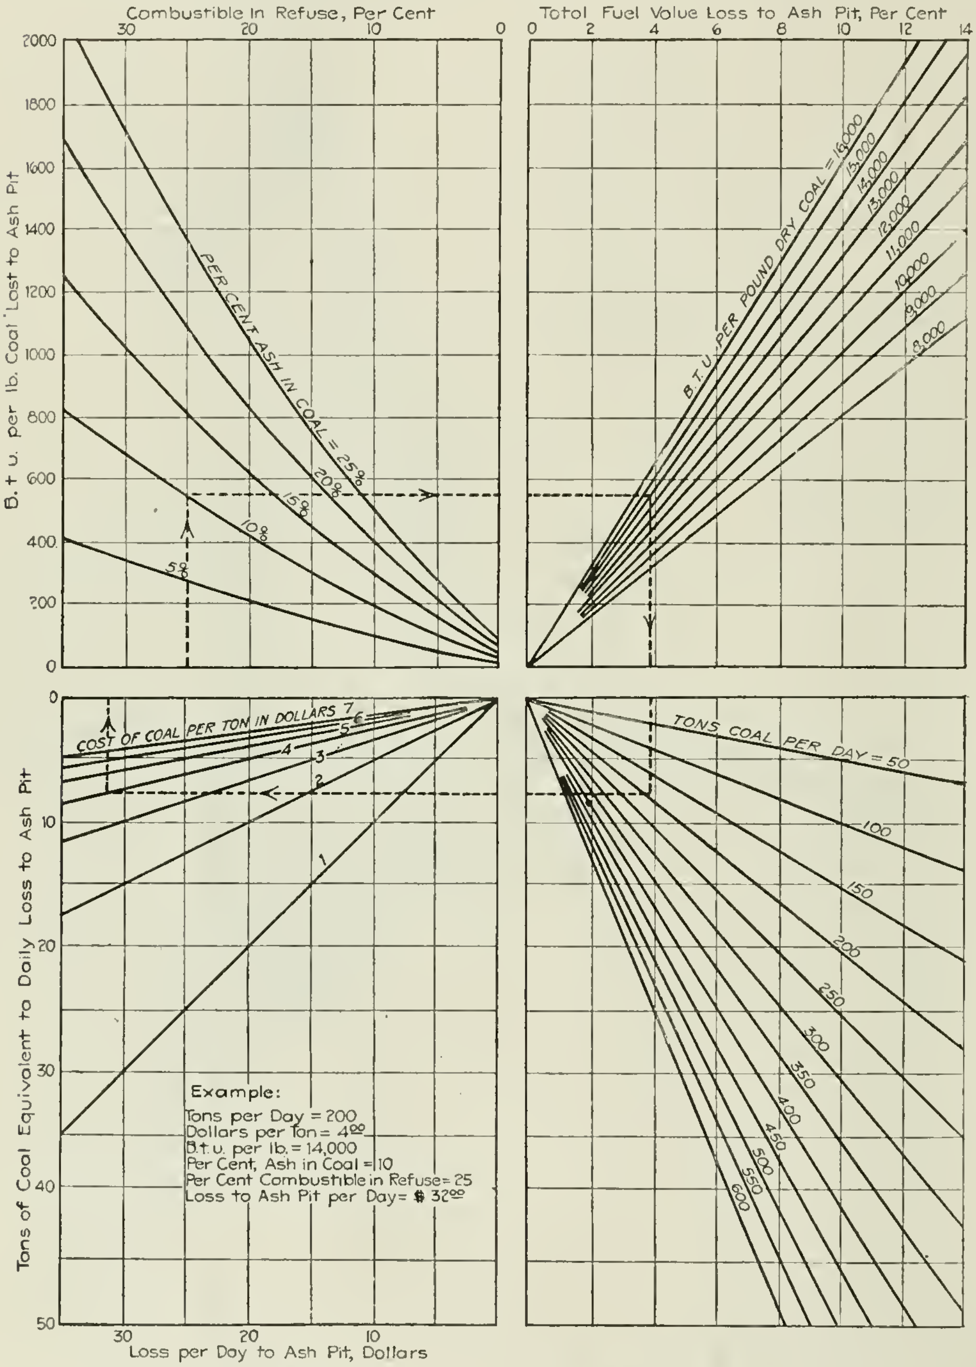

FIG. 6. BOILER-ROOM LOSS CHART, SHOWING FUEL LOSSES TO THE ASHPIT

Ordinarily, CO_2 depends upon the quality of firing, but it also is dependent upon the condition of the boiler setting and of the grates over which the fireman, as such, has no direct control. On the other hand, a good fireman would not allow himself to be deprived of the fruit of his efforts because of a poor setting or of poor grate. Knowing that such defects in the apparatus lead to unnecessary excess air, if the maintenance man fails to do his duty, the fireman naturally will report defects of apparatus to the chief for proper action.

The maintenance man or boiler cleaner can save money by keeping the boiler clean and the baffles in such shape that the boiler will readily absorb heat, so that the flue temperature will be low. An unscrupulous repairman may wilfully neglect the setting and grates in order to admit excess air to cool flue gas so as to increase his bonus. But such a condition would naturally be opposed by an active fireman.

It is true that the flue temperature is dependent not only upon the condition of the apparatus, but also upon the rate at which the fuel is fired. Even in the most efficiently designed installation the percentage of total heat absorbable falls off as the boiler rating increases and the flue temperature rises with increase of load. Therefore it is necessary to base the standard flue temperature for an average load by test. This is comparatively simple for industrial plants where the load is rather steady.

Fig. 5 shows the daily losses in dollars and cents based on the efficiency charts, for any condition measured by CO_2 and flue temperature. That is, under the conditions for the plant illustrated, the daily loss would be \$332. Loss from combustible in ashpit refuse is primarily up to the fire cleaner, who may be a special man or the regular fireman. In case the loss is great owing to poor condition of grates, the fire cleaner, whose interest is thereby prejudiced, should report conditions to the chief for proper action.

The losses on account of combustible in the refuse are measured not only by the percentage of combustible in the refuse, but also by the percentage of gas in the coal. Twenty per cent. combustible in refuse of coal containing 5 per cent. ash means a loss of 205 B.t.u. per pound of coal, while the same percentage of combustible in refuse of coal containing 25 per cent. ash means a 1023-B.t.u. loss per pound of coal.

Fig. 6 shows the daily losses in dollars and cents for any condition measured by percentage of combustible in the refuse and percentage of ash in the coal. That is, under the conditions of the plant illustrated, the daily loss is $32.

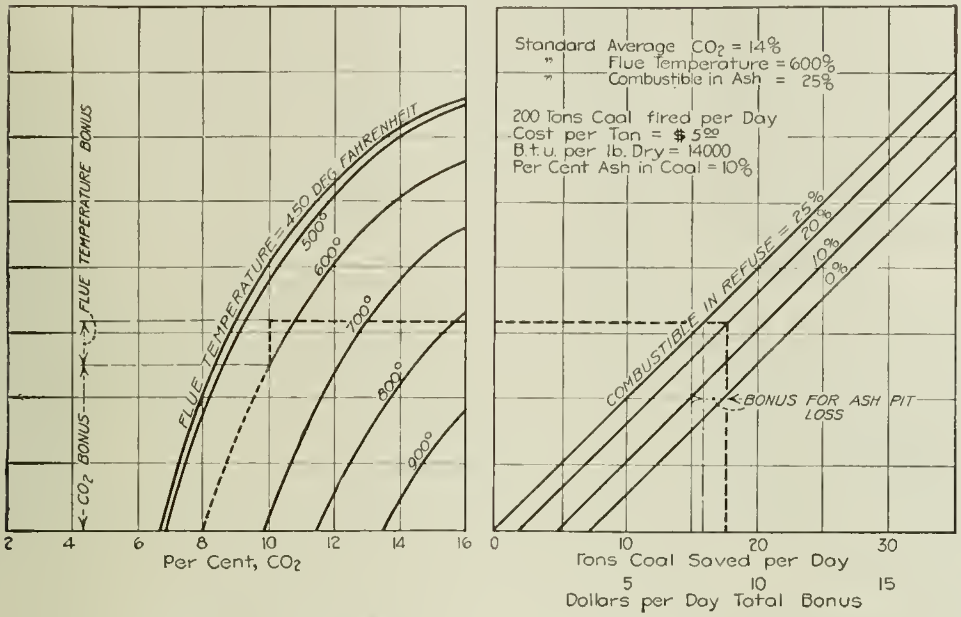

FIG. 7. CHART TO DETERMINE BONUS FOR BOILER PLANT OPERATIVES

Fig. 7 shows a bonus chart with assumed conditions as to quality, quantity and price of coal, with bonus equal to 10 per cent. of the savings calculated from the efficiency chart, to be made by obtaining results better than those measured by the standards of 8 per cent CO_2, 600 deg. flue temperature, 25 per cent. combustible in ash.

Assuming the following average attained:

CO_2, per cent	10
Flue temperature, deg. F.	550
Combustible in refuse, per cent	20

the daily bonus per day equals:

To firemen	$6 10
To boiler cleaners and maintenance men	1 80
To fire cleaners	1 00
	$8 90

The division of the bonuses to individual men is left to the judgment of the management. In the example given, it may be advisable to increase the bonus to boiler cleaners to $3.60 per day, in which case the bonus would be equal to 20 per cent. of this saving to the plant.

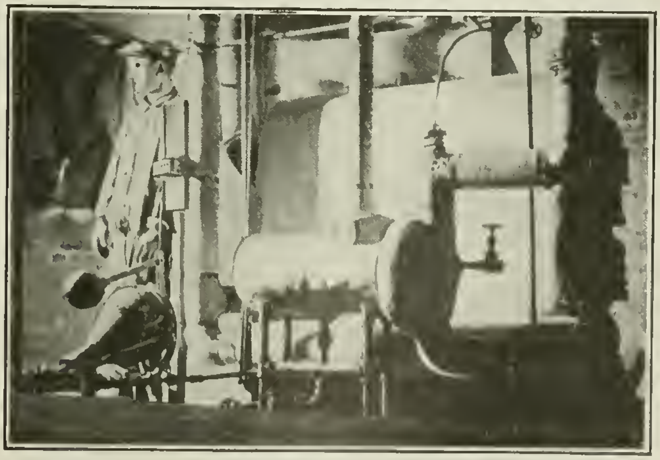
Steam To Heat Water for House Heating

By P. J. Bryant

The use of steam to heat water is not uncommon, but as to the economy of the transfer of the heat from steam to water there seems to be a scarcity of data at hand. We have such an installation at the institution where I am employed, and our operating experiences may be of interest to others. The large buildings are all heated by steam furnished from a central power plant through tunnels, but residences have individual heating systems in their basements. The chaplain's cottage is heated by hot water heated by steam from the tunnel steam main, and the illustration shows a tilting trap to which a tally is attached to meter the condensation during a test of the steam required to heat the cottage.

The heater, also shown, is 32 in. long and 14 in. in diameter, having 16 sq.ft. of heating surface, and the water circulates through the tubes by the thermo-siphon principle. High-pressure steam is delivered through a reducing valve at 2 lb. pressure, controlled by a temperature-regulating valve, so that the water in the system may be maintained at any predetermined temperature. Ordinarily, the condensation from the heater returns to the tunnel system through a seal, but in order to obtain operating data, the calibrated tilting trap with a counter attached, was installed temporarily and all the condensate during the month of February passed through this improvised meter. Daily readings of the counter were taken, and the daily consumption of steam, in pounds of condensation, was plotted for the month against the daily outside temperatures and, although the consumption varied inversely as the temperature change, there was no definite ratio. This is accounted for by variable winds as well as bright or cloudy days, snow, etc. Following is the result: February, 1917, average outside temperature, 25.2 deg.; pounds condensate for the month, 58,270; per day, 2081; cost per month at 20c. per thousand pounds, $11.65; day, $0.416. The cost of steam, 20c. per thousand pounds, was figured from the cost of evaporation at the power plant.

The convenience and flexibility of such a system are at once apparent.



TALLY COUNTER ATTACHED TO STEAM TRAP

Burning Slack Containing Excessive Moisture

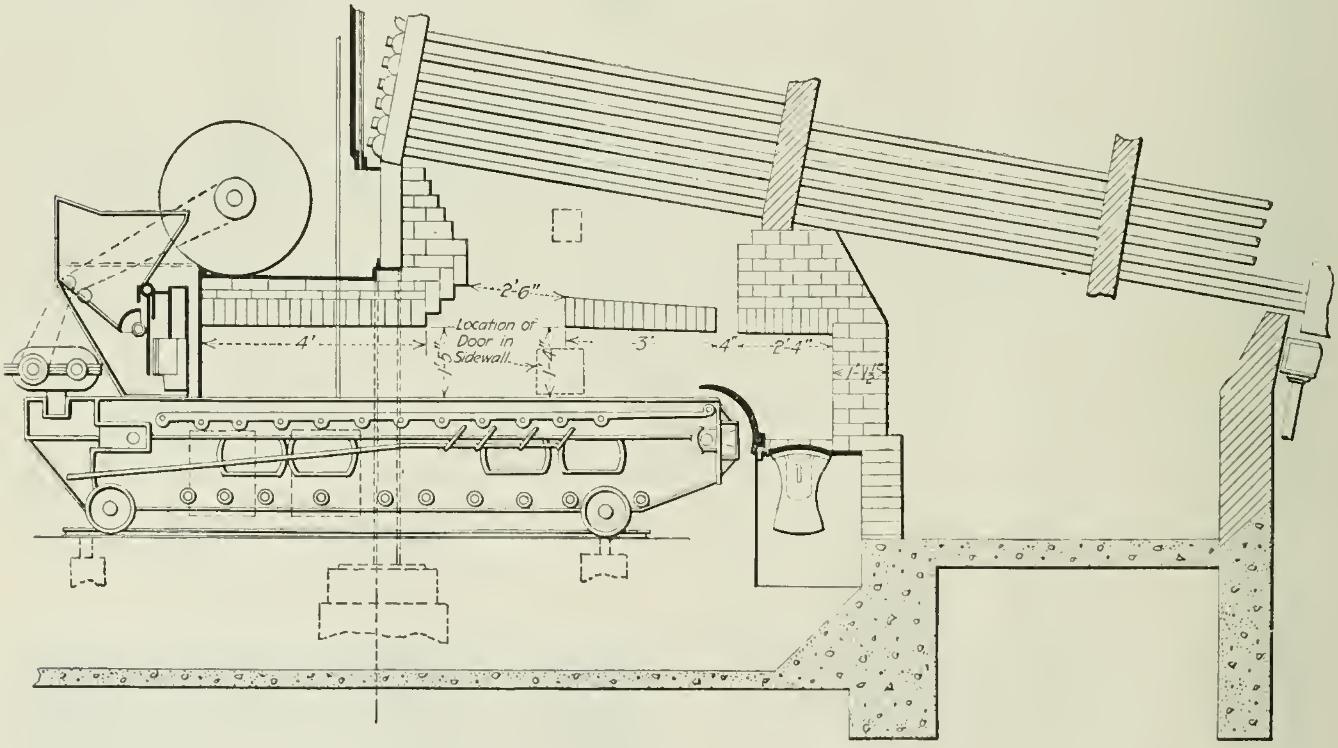
By J. F. McCALL

Superintendent and Chief Engineer, Municipal Power Plant, Calgary, Alberta, Canada

The author burns Drumheller (Alberta, Can.) slack coal, averaging 15 per cent. moisture and 12 per cent. ash on a chain-grate stoker with an arch over the entire grate except for a space 2 ft. 6 in. deep, and the width of the grate long. The long deflection arch extending forward 3 ft. from the brige-wall rolls the flame of the 30 per cent. volatile coal forward far enough to evaporate the moisture as the coal comes on the grate from the feed hopper, avoiding caking of the coal at the rear of the grate.

THERE is sufficient coal in the province of Alberta to supply the whole of the North American Continent for several centuries. The quality varies considerably from surface lignite to the excellent coking coal at Fernie and the valuable semi-anthracite in the Banff district. The known deposits extend over an enormous area, from the Peace River district in the north to the international boundary, and from Medicine Hat to the Rockies. Supplies are sent as far east as Regina, Saskatoon and Winnipeg; the hard coal at Banff finds its way to the coast, and the coke product of the south is extensively used in the smelters across the border. Freight rates, however, govern the extent of the market, the local requirements do not begin to absorb the possible output, and the greater part of the field lies undeveloped. A few years ago a new district, known as the Drumheller field, was opened, and immediately became a factor in the market. This coal was found to average around 11,500 B.t.u. on analysis, but contains excessive moisture, frequently over 15 per cent. I tried the Drumheller slack coal several times on our 335-hp. water-tube boilers with chain-grate stokers, invariably with very unsatisfactory results. It was impossible, owing to the excessive moisture, to ignite the coal sufficiently until it had passed about three feet into the furnace. This was the more disappointing as the freight rate from the Drumheller district was from 20 to 40c. per ton cheaper than the rate on the supply we were using, and in the class of coal we burn the freight is usually the larger item. This, however, did not affect us as much as it did the power plants at Saskatoon and some other towns and cities north of Calgary, all of which have the Drumheller field between them and the field south of Calgary, their freight rates in that case being more than double ours and their cost of production correspondingly higher. Their difficulty in burning the Drumheller coal was the same as we experienced.

Early in 1917 I learned that experiments were being made in Edmonton and Saskatoon with a view to burning the Drumheller coal, the idea being to dissolve the moisture immediately the coal reached the furnace grate. To find out what they were doing and to get some ideas for myself, I went to both places, and found that taking into consideration their higher costs for fuel as compared with ours, the Saskatoon and Edmonton plants had been fairly successful in burning the Drumheller coal. I was satisfied, however, that the arrangement made there of the furnace grate could be improved upon, and we made alterations to eight of our 335-hp. boilers, and eventually evolved the idea represented in the drawing. The chief feature is the center deflecting



SETTING FOR BURNING SLACK HIGH IN MOISTURE AND ASH arch, which deflects the flame from the burning coal to the front of the furnace and thereby ignites the fresh coal as it enters the grate. This flame evaporates all moisture, and the result is an intense heat evenly distributed. We have no trouble in getting 110 per cent. overload out of these boilers, and can burn anything which has anything in it to burn. We have been successfully burning coal with 22½ per cent. of moisture, so that we are able to use freely the slack from the Drumheller field.

We found it necessary to remove an 18-in. sector of the stoker (Babcock & Wilcox chain-grate) casing, to move the bridge-wall back to correspond, so that we could put the stoker back. We considered that it would be desirable to allow an ignition space of 18 in. below the hopper. Ignition takes place at from 8 to 12 in. The reason for the opening at the rear arch is that we found that the fuel on the grate showed a tendency to bank at the end of the grate and that this bank was rich in combustibles. By arranging the opening, a strong draft was created at this point and we were able to burn the carbon out of this bank. In our earlier alterations we allowed only a 4-in. space, but later we found a 6-in. space gave better results. A trial of an 8-in. space proved unsatisfactory. Much depends on the available draft. We used a 0.3-in. draft.

It will be understood that these boilers are equipped with chain-grate stokers of the close-link type. To find out how the arrangement of arches would work with other kinds of stokers or in hand-fired boilers must be a matter of experiment.

In September last we made several tests on the Drumheller coal. In each case the boiler was fired for 24 hours. The test lasted for 10 hours, the object being to test the coal and to obtain working results from the boilers under the new arch arrangement. The following is an average result:

Average pressure, gage, lb. per sq.in	149
Average draft (at furnace), water, in	0.31
Average temperature, steam (saturated), deg. F	364.6
Average temperature, steam (superheated), deg. F	512
Average temperature, flue gas, second pass, deg. F	690
Average temperature, flue gas at damper, deg. F	487
Average temperature water (at heater), deg. F	116
Average CO_2, per cent	11.33
Builder's rating, hp	335
Horsepower developed	458
Percentage of builder's rating	136.7
Water evaporated per pound of coal as fired, lb	6.65
Equivalent evaporation per pound of coal as fired, lb	8.02
Stoker speed, average, ft. per min	2
Thickness of fire, in	4

On analysis these coals from the Drumheller mines are quite uniform. The following is an analysis of an average sample:

Moisture, per cent	15.04
Ash, per cent	12.18
Volatile combustible, per cent	29.95
Fixed carbon, per cent	42.47
B.t.u	11,450

In view of the present shortage of coal these successful experiments will probably prove of interest. It is possible, under the conditions enumerated, to burn any fuel that has anything in it to burn, and it would be quite possible to utilize dumps of wet slack coal which lie at the mouth of coal mines all over the continent, rejected as being useless on account of the moisture content, the accumulation of long periods of exposure to the weather. It is quite reasonable to suppose that there are large quantities of fuels of this class which owners of boiler plants are at present unable to use, in some cases hauling their coal from a distance when they have a suitable fuel close at hand.

Sarco Metallic Gaskets

Lead would make a good gasket with high-pressure steam if it were not so liable to blow out. A lead gasket, being soft, fits into any depression in the flange and gives way for any protruding surface. A copper ring gasket makes a good joint, but being harder than lead, does not conform to the surface of the joint so readily.

A combination of a lead and a copper gasket has been devised by the Sarco Co., Woolworth Building, New York City. It is made for various purposes and in different forms. For flange work, Fig. 1, the lead ring *A* forms the inner member, and just fitting over the outer edge is a copper ring *B* of smaller cross-section. This is to permit the lead ring to come under considerable pressure in tightening up the joints before the flange begins to compress the outer copper ring.

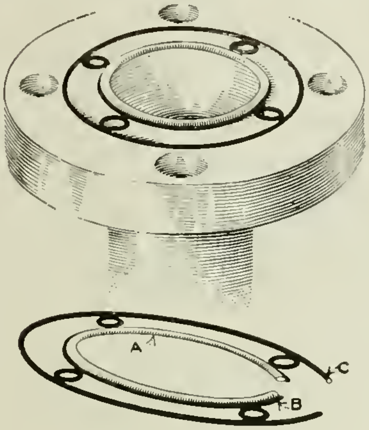


FIG. 1. GASKET FOR WIDE-FACED PIPE FLANGE

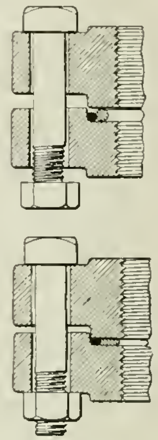

FIG. 2. BEFORE AND AFTER COMPRESSION

With this type of gasket the copper and lead elements, *A* and *B*, are surrounded by a centering ring *C*, the outer diameter of which is a trifle less than the diameter of the circle on which the inner edge of the bolt holes line; thus the bolts, when fitted into place, center the gasket. The centering ring *C* is held concentric with the gasket rings by small copper circles, all members of the gasket being lightly soldered to form a complete unit.

For union connections, where the coupling surfaces to be sealed are relatively narrow, the gasket is composed of a lead and a copper ring lightly soldered together at intervals. The application of the gasket is shown in Fig. 2, which also shows the gasket before and after the joint is tightened. The inner lead ring is of greater cross-section than the copper one and squeezes out into a ribbon form under pressure. The slightly compressed copper ring backs it solidly and prevents the lead ring from blowing out when it is under pressure.

A gasket for superheated steam above the safe working point for lead is made of a number of soft concentric copper rings. For joints the gaskets of which are subject to corrosive fluids from the outside the copper ring is surrounded by a lead one, which, as the gasket is compressed, forms an effective shield against the access of foreign matter. These gaskets are made in various sizes.

The Central-Station and Isolated-Plant Controversy

THE continuation of the hearing before the Public Service Commission for the First District of New York on Mar. 11 was taken up principally with an investigation of the relations between the New York Service Co. and the New York Edison Co. According to the testimony of several witnesses, the New York Service Co. is a company that undertakes the management and operation of isolated plants. In a number of instances the salesmen of the Edison company had suggested to prospective customers the advisability of discontinuing the private-plant generation of electricity and the purchase of current from the Edison company, at the same time allowing the New York Service Co. to operate the steam plant. The case of the Hotel Majestic, mentioned at the hearing of Mar. 4, was an instance of this sort of arrangement.

The purpose of the hearing at the outset was to investigate the service, facilities and rates of electrical corporations with regard to furnishing current for breakdown or auxiliary use, and for buildings having private electric plants. The interest of the Fuel Administration and the controversy between the private plant and the central station are matters that developed naturally from statements made at the first hearing in the case.

It had been suggested that if isolated plants could be supplied with current from the central station during those periods in which the isolated plants had no use for the exhaust steam from their engines, it would be possible to shut down those plants and save a considerable amount of fuel. It was pointed out that the additional burden thus thrown upon the central station would be in the nature of an off-peak load.

At the hearing on Mar. 11, John W. Lieb, of the New York Edison Co., made the emphatic statement that on Manhattan Island, and under Manhattan Island conditions, there was no such thing as off-peak service. To substantiate this assertion, he produced two load curves, one for Dec. 12, 1917, and the other for June 5, 1917. The former represented the maximum load for the year 1917, which was 234,736 kw. The latter showed a maximum load of 200,000 kw., due to a very sudden thunderstorm. The point Mr. Lieb sought to bring out was that during the summer—when the isolated plants would wish to use the suggested off-peak service—the Edison company was likely to be subjected to a demand for current equal to the capacity of the plant, and that at very short notice. From this he argued that an off-peak condition did not exist.

At the same hearing, Charles E. Stuart, representing the Conservation Division of the Fuel Administration at Washington, asked permission to read into the record a statement defining the position of the Fuel Administration in the matter of coal conservation by manufacturers of electric current. In part, his statement was as follows:

> The individualistic way in which fuel is now consumed in cities is not efficient. A ton of coal burned in a large central station will produce at least four times as much electric power as if burned in the average small plant, and if centralized burning could be introduced to a greater extent, the amount of fuel required could be largely reduced without reducing in any way the ultimate production of light and power.
>
> It may be generally stated that in buildings where electric plants are located and where exhaust steam from engines is utilized in the heating of the building, furnishing hot-water requirements, and possibly providing a very small amount of steam for industrial and other processes, such buildings can readily adopt central-station service without a loss of money and at a large percentage of saving in fuel.
>
> In many other cases it might be more economical from the viewpoint of fuel saving to utilize isolated electric plants in conjunction with central-station service. The ideal arrangement would then be to use the combination of services in such a way that no exhaust steam is sent to the atmosphere to be lost.
>
> It is the duty of the Fuel Administration to devise means for securing a curtailment in the use of fuel in ways which will impose a minimum of hardship. It is believed that there are many plants not only in New York, but throughout the entire country, which could, at least temporarily, shut down their own electrical machinery and purchase power from others at a financial advantage to both parties and with a considerable saving in fuel.
>
> The Fuel Administration believes that if even a comparatively small proportion of the plants throughout the country which could save fuel in this way at a profit to themselves would do so, it would prove a tremendous help in meeting the fuel situation with which the country is confronted, and in winning the war.
>
> While it may appear that the interests of the central station are being benefited to a large degree, such is not of necessity the case. In some cases, central stations may be shut down. In any event any connection between a central station and a building or a manufacturing plant that is affected, will, of necessity, be for the period of the war only or through the period where the coal situation is critical. The machinery of the isolated plant can be readily preserved through this period of necessity. Under these circumstances the heavy expense attendant upon the making of the connection by the central station may completely or even more than offset any profit which could be expected of such a load through a short period.
>
> At this point another very important question, that of the release of the operatives of the plants, presents itself. In those cases where small electric plants are closed down entirely, there will be a larger number of men available than in cases where a partial closing down is brought about. In any event these skilled men are vitally needed in many of the war industries of this country, and provision is now being made whereby men of such training will be assisted in obtaining profitable work suitable to their ability.
>
> Again, the conservation efforts of the Fuel Administration are being directed in order to conserve the interests of all with the least inconvenience and cost and with the object of making the coal supply that is available go just as far as possible and to prevent the necessity of further drastic measures such as were necessary in January. In this spirit the Fuel Administration invites the coöperation of the isolated plant owner, whether the question be of connecting in on the lines of a central station or whether it be that of operating his plant to maximum efficiency. The alternative will be at least the one if not the other.
>
> The administration at this time has no idea of attempting to bring about any such result by means of orders, or of even suggestions that fuel be saved by the closing of isolated plants where this would cause hardship to the owners, not commensurate with the benefit derived by the public. It is interested in the present hearings, however, in the hope that they will set forth the facts and also the savings which are possible in certain cases in so convincing a way that each plant owner will consider himself a volunteer member of the administration, charged with the duty of investigating his own condition in a nonpartisan way and, where circumstances warrant it, of taking the necessary steps to secure the saving.

The second paragraph of the foregoing statement is of especial interest to the owners of isolated plants in which a small part of the steam generated is used in producing electric current while the greater part is used for heating, drying, cooking, etc. Its conclusions are diametrically opposed to the results of experience in many instances in which isolated plants discontinued the generation of electric power and adopted central-station service, at the same time continuing to produce steam for heating and other purposes. The testimony of Copeland Townsend, of the Hotel Majestic, at the hearing of Mar. 4, showed that the adoption of such a plan not only failed to save coal, but placed the plant under additional heavy expense.

Mr. Stuart, who issued this statement on behalf of the Fuel Administration, is an electrical engineer and a member of the firm of Stuart, James & Cooke, whose business it was, previous to the war, to investigate power plants with a view to determining whether they could not be supplanted economically by electric power from large central stations. In an interview with the editor of *Power* Mr. Stuart said that his firm had investigated perhaps 800 plants, most of which were connected with mining operations, and that the majority of these eventually changed from individual service to central-station service.

When he was asked whether the statement he had read into the record was an expression of his own individual views, he replied that it represented the consensus of opinion of a number of the Fuel Administration's engineers, himself included; however, he finally admitted that there were numerous small plants, such as those carrying combined heating, power and lighting loads, in which the substitution of central-station service would undoubtedly fail to show a saving of coal.

This is the opinion held by many engineers who have carefully considered the problem. At the January meeting of the American Institute of Electrical Engineers, a paper was presented by Lynn S. Goodman and William B. Jackson on "The Effects of War Conditions on Cost and Quality of Electric Service," in which the authors made the following assertions: "When viewed from every standpoint, it will be seen that the economical central power generating station is the proper medium for the supply of the large power requirements arising on account of the war"; and "these advantages of the central-station power are so large that it is advisable for the Government to use every reasonable means to encourage the central-station companies and discourage individual power plants during the war period."

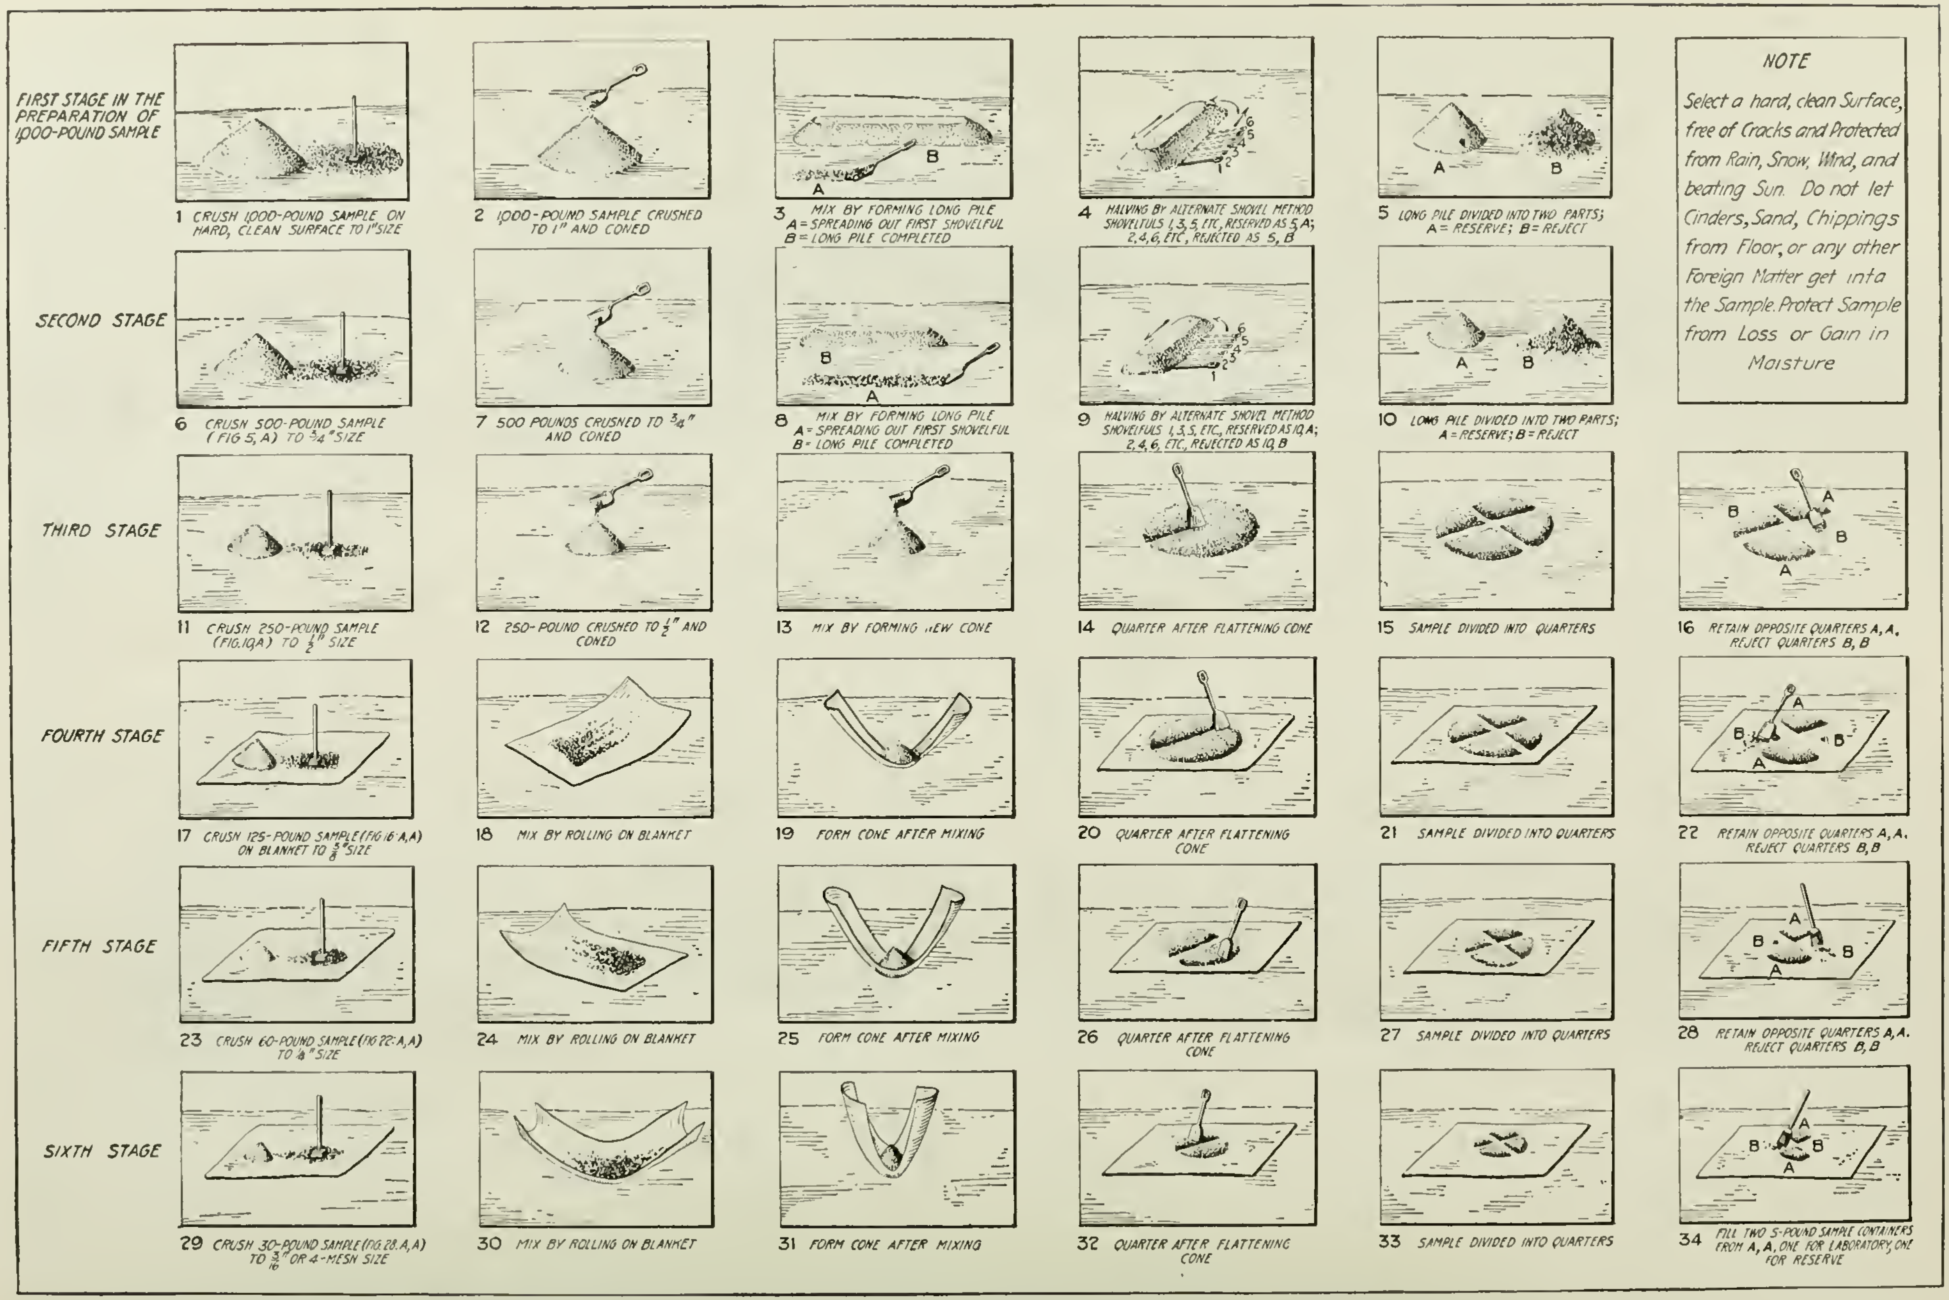
As might have been expected, such sweeping claims as these were not allowed to stand unchallenged. Bion J. Arnold, in discussing the paper, said:

> There is no question in my mind that where you can utilize steam for heating and have some use for that heat aside from merely heating in winter time, there is an advantage in having an isolated plant. For instance, in a hotel, where you need steam for cooking, under such conditions as that the isolated plant, in my judgment, will be superior to the central-station power; that is, it can produce its own heat and electrical energy cheaper than it can buy it from the central station. That is the only instance, in my experience, where I have found that it would work out in that way; otherwise, it is generally cheaper to buy energy from the central station.

The same topic was referred to in the discussion by Mortimer Freund, who said:

> I do not believe it proper to allow to pass unquestioned the authors' statement that "the economical central-power-generating station is the proper medium for the supply of large power requirements arising on account of the war," and further that "it is advisable for the Government to use every reasonable means to encourage the central-station companies and discourage individual power plants during the period of the war." Both of these statements are too sweeping in character and, as a matter of fact, only justifiable for such cases, where a careful and disinterested consideration of all the circumstances will warrant such a conclusion.
>
> It seems to me that the second statement might better be substituted by the following: It is advisable for the Government to encourage all consumers of fuel to use every effort to fulfill their heat, light and power requirements by such means as will utilize fuel most economically and do away with all existing wastes which are preventable.
>
> There are industrial plants, for example, where a great part, if not all, of the electricity used is virtually a by-product due to the utilization of exhaust steam from the electrical generating unit. I have in mind a large industrial plant which up to 1915 operated two separate boiler plants, the output of one of which was utilized almost exclusively for drying. The exhaust steam from the electric generating plant was wasted in the nonheating season and only partly used during the heating season. Substitution of purchased electricity had been suggested. Since 1915 the exhaust steam has been utilized in place of live steam, the use of one of the boiler plants has been discontinued and the actual cost of electricity, in view of the use of the exhaust steam, is far less than the best price which outside service can offer. The action on the part of the management of this mill in undertaking the change necessary to permit of this has not only paid them well on the investments made, but has benefited the country to the extent of reducing their fuel consumption. Surely, the authors do not recommend that the Government discourage such an individual generating plant, although such a conclusion might be drawn from their statements.
>
> I hold no brief for the private power plant. There are unquestionably many private plants now in operation which should be supplanted by central-station service. It has been my own practice to recommend central-station service in all cases excepting those where the installation of a new private power plant or the continuance of an existing plant would show a substantial saving in the cost of operation or other advantages of substantial worth. The private power plant is not an obsolete idea, as some have been trying to tell us. There are cases where it results in the most highly efficient production of heat, light and power. Each case should be decided upon its own merits and not on the basis of sentiment. Sweeping generalities are, in my opinion, unwarranted and misleading.
>
> The central-station service and the private power plant should not be in conflict, especially at the present time. Each has its proper sphere, and conditions may have arisen or will arise in particular instances to cause one service to supplant the other. It has been and will be to the mutual advantage of many central stations and private plants to coöperate by exchanging of service at different times of the day or during different seasons of the year. Friendly consideration and coöperation should exist between central-station management and the management of private power plants, so that maximum efficiency in operation may be maintained and the greatest benefit assured to the general public. This is a policy in keeping with the spirit of the times and necessary for the conservation of our natural resources.

If we help Uncle Sam by buying Liberty Bonds, we help ourselves. The buying of Liberty Bonds resolves itself into an expression of the highest form of intelligent self-interest. A British sergeant told a cocky young American, just off a troopship, "You aren't fightin' to save France, an' you aren't fightin' to save Belgium; you're jolly well fightin' to save your children and your grandchildren." The same line of reasoning applies to the buying of Liberty Bonds, for in the last analysis you aren't buying them to help a mythical old gentleman in a bestarred swallow-tailed coat and striped trousers who is having a lot of trouble purchasing ships and shoes and sealing wax; you're jolly well buying them to help yourself.



1 CRUSH 1000-POUND SAMPLE ON HARD, CLEAN SURFACE TO 1" SIZE

2 1000-POUND SAMPLE CRUSHED TO 1" AND CONED

3 MIX BY FORMING LONG PILE
A = SPREADING OUT FIRST SHOVELFUL
B = LONG PILE COMPLETED

4 HALVING BY ALTERNATE SHOVEL METHOD SHOVELFULS 1, 3, 5, ETC., RESERVED AS 5, A; 2, 4, 6, ETC., REJECTED AS 5, B

5 LONG PILE DIVIDED INTO TWO PARTS; A = RESERVE; B = REJECT

6 CRUSH 500-POUND SAMPLE (FIG 5, A) TO 3/4" SIZE

7 500 POUNDS CRUSHED TO 3/4" AND CONED

8 MIX BY FORMING LONG PILE
A = SPREADING OUT FIRST SHOVELFUL
B = LONG PILE COMPLETED

9 HALVING BY ALTERNATE SHOVEL METHOD SHOVELFULS 1, 3, 5, ETC., RESERVED AS 10, A; 2, 4, 6, ETC., REJECTED AS 10, B

10 LONG PILE DIVIDED INTO TWO PARTS; A = RESERVE; B = REJECT

11 CRUSH 250-POUND SAMPLE (FIG. 10, A) TO 1/2" SIZE

12 250-POUND CRUSHED TO 1/2" AND CONED

13 MIX BY FORMING NEW CONE

14 QUARTER AFTER FLATTENING CONE

15 SAMPLE DIVIDED INTO QUARTERS

16 RETAIN OPPOSITE QUARTERS A, A, REJECT QUARTERS B, B

17 CRUSH 125-POUND SAMPLE (FIG 16: A, A) ON BLANKET TO 3/8" SIZE

18 MIX BY ROLLING ON BLANKET

19 FORM CONE AFTER MIXING

20 QUARTER AFTER FLATTENING CONE

21 SAMPLE DIVIDED INTO QUARTERS

22 RETAIN OPPOSITE QUARTERS A, A, REJECT QUARTERS B, B

23 CRUSH 60-POUND SAMPLE (FIG 22: A, A) TO 1/4" SIZE

24 MIX BY ROLLING ON BLANKET

25 FORM CONE AFTER MIXING

26 QUARTER AFTER FLATTENING CONE

27 SAMPLE DIVIDED INTO QUARTERS

28 RETAIN OPPOSITE QUARTERS A, A, REJECT QUARTERS B, B

29 CRUSH 30-POUND SAMPLE (FIG. 28, A, A) TO 3/16" OR 4-MESH SIZE

30 MIX BY ROLLING ON BLANKET

31 FORM CONE AFTER MIXING

32 QUARTER AFTER FLATTENING CONE

33 SAMPLE DIVIDED INTO QUARTERS

34 FILL TWO 5-POUND SAMPLE CONTAINERS FROM A, A, ONE FOR LABORATORY, ONE FOR RESERVE

The Buying Line and the Firing Line

THE Buying Line Over Here and the Firing Line Over There, which our cartoonist has depicted in the foreword of this issue, makes us ask the question, Can there be any comparison? Although the buying of Government securities by those at home is absolutely necessary in order that supplies in a never-ending stream be kept flowing to the boys at the firing line, a comparison between the two is difficult of comprehension.

How many of us at home have made any real sacrifice? True, we have our wheatless days and our meatless days, but so far no eatless days, and whatever restrictions we have made, those of us who have made them, regarding our stomachs, have found it to have a beneficial effect. Therefore, in this respect our sacrifice has not been a hardship at all, but something that we should have done for our own physical well being, war or no war.

Most of us are employed in as congenial or even more congenial vocations than ever before, at better wages than received in pre-war periods and to a very large extent indulging in the same luxuries we always have.

As to buying Liberty Bonds, is this a sacrifice—to invest money in your Government's bonds, a security that is the safest investment in the world at a rate of interest that is as good and in some cases better than can be obtained in a savings bank? This act, even leaving all patriotic motives out of it, is nothing more nor less than a sound common-sense business transaction, in which you are absolutely sure of benefiting yourself financially.

How about the boys on the firing line over there—those who have given up their home and its comforts and all that most of us hold dear, for the life of the trench and the dugout? This is best expressed by the following letter received from Citizen Soldier No. 258, ——th District, National Draft Army. This letter should make every American do more than think. It should make him act.

> They say, who have come back from Over There, that at night the troubled earth between the lines is carpeted with pain. They say that Death rides whistling in every wind, and that the very mists are charged with awful torment. They say that of all things spent and squandered there young human life is held least dear. It is not the pleasantest prospect for those of us who yet can feel upon our lips the pressure of our mothers' good-bye kiss. . . . But, please God, our love of life is not so prized as love of right. In this renaissance of our country's valor, we who will edge the wedge of her assault make calm acceptance of its hazards. For us the steel-swept trench, the stiffening cold—weariness, hardship, worse. For you, for whom we go, you millions safe at home—what for you? . . . We shall need food. We shall need care. We shall need clothes for our bodies and weapons for our hands. We shall need terribly and without failure supplies and equipment in a stream that is constant and never-ending. From you, who are our resource and reliance, who are the heart and hope of that humanity for which we smite and strive, must come these things.

For us at home to do our bit isn't enough. Our utmost is mighty little compared to the supreme sacrifice our men are willingly making. We can't all fight, but we can all support the Government. We can all economize and we can invest our savings in Government securities. Remember this war won't be won if we depend on the other fellow to win it. It's up to you. Your bit isn't enough; we must see to it that the Buying Line Over Here is maintained in a way that will make it possible for the boys at the front to make the firing line Over There impregnable. One way of doing this is to buy all the bonds you can of the Third Liberty Loan, to be offered on Apr. 6.

Bandar-Log or Bee?

FROM the time a monkey opens his eyes in the morning until drowsiness overpowers him at night, he is pretty much a law unto himself. He does anything he wants to, when he wants to, and as long as he wants to. A whimsical individualism sums up his philosophy of life. The day's end finds him just where he was in the morning. The tribe—bandar-log, Kipling calls them—respond to any leader of the moment and as quickly quit him to follow another or to fetch up individually with a brand-new, suddenly caught and all-absorbing idea.

Like any other philosophy, it is a charming one if you like the net results of it. The monkey does. On the contrary, the bee doesn't. The bee insists on organization by functions. His philosophy is self-sacrificing, vigorous and stern—a Spartan philosophy applied to production. "Beeficiency" is the Taylor System raised to the nth power; and the bee doesn't get the honey.

If the bee had sense, he'd maintain his present organization a few hours a day—which would easily supply his wants—and be a bit bander-logish the balance of the time. But he cannot. The reason is because he doesn't think. He's a machine that is a part of a bigger machine. On the other hand, if he did think, he'd immediately tend to become individualistic, and the moment that happened the organization would begin to wabble. There would be argument about how the comb should be built, who should build it, who should boss it, how much honey should go to each; societies for the prevention of this and that would be formed. Social workers must eat; so must bosses; so must societies for the prevention of things.

Nature did not see fit to devise a species having the merits of both bandar-log and bee—a sort of bandar-bee.

A bandar-bee would help us a lot just now. It would be the real super-thing. It would be highly coöperative for a few working hours and highly individualistic the rest of the day. It would accept the notion that working together bee-fashion is the answer to the question of maximum production in minimum time; but being a super-thing, it would reject the notion that the honey gathered should all get into the hands of a few crafty speculators to be sold back at the speculators' price. It would control distribution with the same bee-like coöperative efficiency that it used in production.

It would accept the axiom that self-expression is necessary to a thinking super-thing—that monkey play in a monkey way is after all the best fun in life. It would approve the bandar-log system, in which the individual in his idle hours may sit on a limb and philosophize, or try a new way of weaving twigs, or join the bunch in a frolic, or play with the kids.

Obviously, the bandar-bee would be a clear and direct thinker. He would be an intense individualist—so intense an individualist that in order to have the maximum number of hours a day for individualism, he would sink his individualism when he came to his production and distribution hours, and be an intense coöperator. He would treat as wasters those superbees who would work themselves and others without any thought of the monkey play, merely to amass a personal pile of honey. There would be piles of honey, adequate personal piles, but not huge ones.

Individualism and self-interest are about the same thing. The date when the bandar-bee will appear on the earth depends upon the amount of hammering which mankind must undergo, to pound into it a realization of the fact that in the long run self-interest can be most permanently promoted by intense and unselfish coöperation in production and distribution.

The Water-Power Bill

A SPECIAL committee of eighteen members of the House has devoted a week to hearings upon the Administration's Water Power Bill. This bill, which is a proposed House substitute for the Shields Bill as passed by the Senate, creates a commission consisting of the Secretaries of War, Interior and Agriculture and having an executive officer to be appointed by the President. This commission may grant licenses for the development of power projects upon navigable streams or streams located upon public lands for terms not to exceed fifty years, at the end of which time the Government may renew the license, transfer it or take the project over itself.

The tentative draft of the bill, commented upon in *Power* of February 19, provided that the Government on recapture should pay for the project "the fair value not to exceed actual cost of the property taken." Inasmuch as a large proportion of the original investment might have been retired through depreciation and amortization during the fifty years' tenure, it would be possible, as was pointed out in the editorial referred to, for the promoter, in addition to a fair profit during that time, to receive back much more than he put into the project. This has been taken care of in the draft of the bill now before the committee by providing that the Government shall have the right, on the termination of the license, to take over the project upon the payment of the "net investment" of the licensee. This net investment is defined as the actual legitimate cost as defined and interpreted in the "Classification of Investment in Road and Equipment of Steam Roads, issue of 1914, of the Interstate Commerce Commission" plus similar costs of additions thereto and betterments thereof minus the sum of the following items properly allocated thereto, if and to the extent that such items have been accumulated during the period of the license from earnings in excess of a fair return on such investment: (a) Unappropriated surplus, (b) aggregate credit balances of current depreciation accounts, and (c) aggregate appropriations of surplus or income held in amortization sinking fund or similar reserves or expended for extensions or betterments.

Dependence for the regulation of rates, service, issue of securities, etc., is placed upon the public-service commissions or other authorities of states where such regulation is provided. Where no such local regulation exists, the Federal commission has authority. A rental, not less than ten cents per horsepower per annum, is to be charged, except to states and municipalities. Whether this is based upon the potential, installed or developed capacity, or the amount of power sold is not clear. This, if kept to the minimum, represents not much more than an administrative charge, but is applied in part to the improvement of the lands and rivers upon which the project is located. There was no objection to the rental, as the operator will simply pass it on to the consumer. One of those who took part in the discussion suggested making the maximum fifty cents per horsepower annually so that it would not become a burden in meeting competition.

The presentation was arranged to show the benefits that would accrue from the development of the powers; then that the privileges that the Government is offering are not so valuable as is popularly supposed because water powers can compete with steam power only under favorable conditions, and that projects must not be burdened with too many restrictions and handicaps; then to seek the modification of the bill in those respects in which these handicaps might be supposed to lie. These were chiefly in the tenure and recapture provisions.

Our preference has been for a license revocable at any time on repayment of the net investment. There is an argument for the term license, however—not that which is usually advanced, that the project cannot be financed without a franchise valid over the lifetime of a long-term bond, for the recapture provisions of an indeterminate license could protect the investment however soon it was taken over, but that the chance of making a profit is the incentive for the promoter. If the Government can take it by restoring what has been put into it as soon as it begins to pay a profit, his chance for remuneration is jeopardized.

The bill provides that the commission may in its discretion give preference to applications for licenses by states and municipalities for developing power for state and municipal purposes. Municipal purposes are defined as "all purposes within municipal powers as defined by the constitution or laws of the state or by the charter of the municipality where any such purpose is directly pursued by the municipality itself with the primary object of promoting the security, health, good government or general convenience of its inhabitants," and licenses may be issued without charge for the development, transmission or distribution of power solely for state or municipal purposes.

As the Federal Government would be unlikely to recapture a project and operate it by selling the power, the opinion seemed to be that unless it acquired it for a governmental purpose, as for making nitrate, ammunition, etc., or operating Government-owned railways, projects would, on the expiration of the licenses, pass into the possession of the municipalities that they served unless satisfactory terms could be made for renewal. Municipality, as used in the bill, means a city, county, irrigation district or other political division of a state competent under the laws thereof to carry on the business of developing, transmitting or distributing power.

At the present rate of development it is difficult to predict what social and industrial conditions may be fifty or more years from now, but the bill appears to safeguard as well as possible the interests of the public while offering security to capital and incentive to enterprise.

America Calls to Americans

ON APRIL 6, one year from the day the United States entered the war, the Third Liberty Loan will be offered for subscription. It is imperative that it should be oversubscribed. It is frequently asserted that the moral effect of a magnificent response will be felt among our Allies and by the enemy. While this is undoubtedly true, there is another reason why the money should pour in, which must not be overlooked—*It is needed!*

Each day sees some new demand for extraordinary expenditure. The shipbuilding program alone will entail an outlay that must be stupendous. The building of aircraft calls for immense appropriations. And these are only two items in the cost of the war. The maintenance of troops at home and abroad and a hundred other expenses are mounting every day.

There can be no question that this Third Loan will be made at a time when the war has reached a critical stage. Money and more money must be expended. The Allies can no longer contribute in amounts that are necessary at this crucial time. America must furnish the sinews of war. And America calls to Americans. That is all that need be said. To think that she should appeal in vain is impossible.

The school children of New York City alone are preparing to raise $50,000,000. Surely, American men and women would be ashamed to look these children in the face if they failed to grasp the privilege which is offered of aiding America at this critical time in the history of the nation.

Conservation of Natural-Power Resources in Australia

THE article on hydro-electric power development in Australia and New Zealand, published on page 465 of this issue touches a question which is just now of great interest to the American reader. It appears that the Australians have decided to make as wide a use as possible of their natural-power resources in the future, and also that they are not willing that these resources shall be exploited by private capital, but shall be developed by the nation in the interest of the nation.

The realization of the great importance which hydro-electric development will play in the economic life of Australia and New Zealand so far has found expression in the carrying out of vast schemes of hydro-electric power generation. Of these, the great development contemplated in the North Island of New Zealand deserves special attention. When completed, this enterprise will not only tap most of the best power sources known at present, but will also be interconnected in such a way as to make the resources of each development available for all the other developments.

The whole of the work is carried out by the government, and the government will be the owner of the generating stations and the means of distribution. The cities and large consumers of electrical power will buy from the government. By this scheme a guarantee is offered that the resources of the country will be developed so as to give the best results.

Australia and New Zealand have been very farsighted and fortunate in taking early steps to prevent the unhealthy exploitation of their natural-power resources. Laws passed years ago have made the undertaking of electrical enterprises dependent upon government license, and when the time came to tap the great dormant power resources of the country the government's position was strengthened by additional laws giving to the nation virtual control of all the existing resources.

Does Rhode Island Need a License Law?

DURING the last few weeks we have published accounts of an unusually large number of boiler explosions. On page 463 of this issue is a report of another one in which three persons were killed and four were seriously injured.

Nothing is definitely known as to the pressure carried at the time. One hour and forty minutes before the explosion the gage registered fifty-five pounds pressure and sufficient water was showing in the gage-glass. Two factors stand out prominently, one being that the safety valve was found frozen solid the day after the explosion, although the weather was not sufficiently cold to produce this result. The other is that the man who was operating the boiler was performing this duty without a license, and, furthermore, the State of Rhode Island does not make it necessary for a boiler attendant to have one.

Some good may result from this explosion in that it may lead to the adoption of a city, if not a state, law governing the supervision of steam plants and the licenses of those engaged in their operation.

Suggested Caution Warranted

In spite of the coal shortage this winter, the showing made in the annual statement of the Rhode Island Coal Co., just issued, is the worst on record, with a deficit of more than half a millions dollars. The December deficit alone was $102,347.76. And yet coal mining is generally a profitable business, and Rhode Island coal has lasting qualities.—*Boston Globe*, Feb. 27, 1918.

Before purchasing any of the 400,000 shares of stock offered in the pamphlet previously mentioned, investigators would do well to make a thorough investigation, visit the mine and form their own conclusions.—*Power, Oct. 5, 1909.*

Does a Bonus System for Firemen Pay?

Many articles have been written advocating bonus systems for firemen on a CO_2 or high-evaporation basis, but my experience is that competition among firemen has not always produced the desired results when the actual conditions are known, for, however dense and ignorant of the laws of combustion a fireman may be, it does not usually take long for him to learn how to beat a CO_2 recorder or to find means whereby he can juggle evaporation.

Almost every fireman, whether he is working under a bonus system or not, likes to receive credit for a good day's work, and there are always a few unscrupulous ones who will adopt underhand tricks in order to increase their own prestige. The percentage of these unscrupulous ones may be small, but they are usually present in sufficient number to defeat the object of any system or friendly competition ever devised or inaugurated.

In a small hand-fired installation where a CO_2 recorder is used, the fireman on each watch tries to make a good showing on the chart. One fireman in cleaning the fire under the boiler to which the recorder happens to be attached does a "half job"; merely pulling out the loose dirt and clinkers, leaving the heavy clinker formation on the bridge and side walls, cleaning the fire just sufficiently to enable him to "get by" for the remainder of his own watch. As a result of such a cleaning, the CO_2 on the chart is down for but a short time. When it is the next man's turn to clean that particular fire it is in an awful condition—the clinker formation on the walls is hard as cement and has covered a large part of the great area. This fireman is perhaps conscientious in the discharge of his duties, and by hard labor and loss of considerable time he manages to remove the clinker and regain the lost grate area. But the record he has made on the chart is anything but "pretty," the CO_2 has been down for a long interval.

The chances are that the unscrupulous fireman is credited with being a speedy and skillful man, while the conscientious fellow is criticized for his poor showing. The usual result is that the fireman so censured, rather than start a controversy, either seeks another position or else resorts to the other fireman's underhanded methods. The efficiency of the plant suffers in either case. When there is considerable difference in the results obtained by the different firemen, the engineer should ascertain the true reasons for such before bestowing praise or censure.

Some time ago I read an article about a certain plant where a competition was fostered between the boiler-room crews on the different shifts to see which crew could obtain the best evaporation. The results so obtained and published were misleading, the actual conditions were not made known—some of the tricks resorted to by the night crew to bolster up the evaporation on that shift. The coal passer who was responsible for the weighing of the coal, after having got well caught up on his work was in the habit of going to a quiet corner best known to himself, for a little nap. The fireman would seize this opportunity to sneak in an extra car or two of coal, which of course was never recorded. "Cracking" the blowoff and other means they had of getting rid of the water were resorted to. Whether any such methods were practiced by the crews on the other shifts or as to how long these practices went undetected, I do not know, but certainly the competition so fostered came far from attaining the desired results.

In my estimation intelligent and appreciative supervision, good working conditions, fair wages and reasonable hours will pay the plant owner greater dividends than all the bonus systems or competitions ever devised or inaugurated. By reasonable hours I do not mean seven days a week for, however interested an engineer or fireman may be in his work, he needs one day of rest and relaxation if he is to maintain his maximum efficiency. I am glad to note that there seems to be a growing tendency among the more reasonable employers to recognize this fact. L. L. SPRAGUE.

Andover, Mass.

There Should Be an Ash Inspector

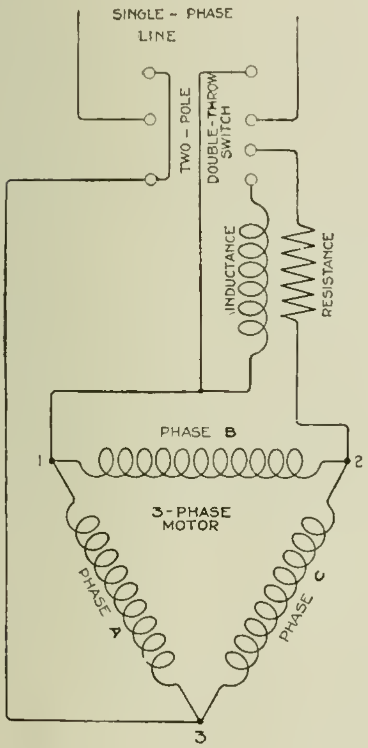
Reading the editorial, "Why Not Have an Ash Inspector?" in the issue of Feb. 19, page 267, reminds me of a suggestion that I made the local fuel administrator some time ago—to appoint a capable man clothed with authority to visit plants, commercial and domestic, and to say to the owners or operators: "Your fuel is not suited to the conditions," or "Your grates are not right," or "Your draft is not handled rightly," "Your settings are leaking," or any of the many things that go to prevent getting good results. He should show the operator how to handle the furnace, then see that instructions are followed or cut the fuel off, whether it be the fault of the installation or of the men handling it. In homes there are many heaters that are wasting a lot of fuel where an expert could help out, and the owners would be glad to save if they knew what steps to take to do so.

My suggestion to the fuel administrator was not acted on for the reason, as stated, that there was no provision for such a man nor funds with which to pay one. Why should a power plant, where the men and the company are trying in every way to save and run economically, be compelled to stop to save coal for those who are wantonly wasting it? It is not fair and is very discouraging to the ones that are trying and "working their heads" off to save. There certainly should be an ash inspector and one who knows something besides what he has learned from some textbook.

Binghamton, N. Y. ASA P. HYDE.

Operating Polyphase Motors Single-Phase

The letter in the issue of Jan. 29, by F. W. Plumb, on operating two-phase motors single-phase recalls two incidents in my experience along a similar line. A power company in a Southern city made it a practice to run long single-phase primary extensions out into the country in order to furnish lighting and single-phase power to the farmers. One such customer had ordered a corn shredder and a single-phase motor to drive it. The machine was delivered, but the motor was delayed in transit and it became necessary to get the machine running. No other single-phase motor of sufficient size was available, so it was decided to attempt the work with a large three-phase machine. The motor was installed and a phase-splitting device built, as shown in the figure, to assist in starting. After some adjustment of the phase-splitting coils and a little assistance on the belt, the motor came up to speed with the switch in the down position; then the switch was thrown up, which connected the motor directly to the single-phase current. The motor continued to operate in this manner until the single-phase machine was delivered and installed.



PHASE-SPLITTING CONNECTION

In another case a small central station had two generators, one single-phase and the other a three-phase. The single-phase machine was used only in emergencies and to furnish light when there was no power load on the plant. One of the manufacturing plants in the town used several small three-phase motors and one larger machine of the same type, which, however, was only partly loaded. The three-phase generator broke down and required several days for repairs to be made; in the meantime, the power consumers desired to continue operations.

A temporary single-phase connection was made to the large motor and a split-phase device constructed for the purpose of starting the large machine. After the large motor was started on the single-phase circuit, it was thrown over on the three-phase line, one phase of which was connected to the single-phase generator. In this way the three-phase motor was made to operate as a single-phase to three-phase converter in addition to pulling its own load on single-phase power, so that the small motors could be started and operated on three-phase power as formerly. The large motor now operated at nearly full load, but the small motors took about the same power from the circuit as when supplied from the three-phase generator.
D. R. SHEARER.

Johnson City, Tenn.

Single-Phase Operation Caused Low Power Factor

With frequency changers operating in parallel, both the motors and the generators must be in phase. With the motors locked in phase with the main generators and the motors having a different number of poles than the generators of the frequency changers, there is evidently only a certain relative position in which the generators of the sets will be in phase. If this position is not obtained when the motors are switched in, it becomes necessary to do what the operators term slipping poles on the motor. This is accomplished by opening the motor switch long enough for the synchronizing indicator on the motor to make a complete revolution, indicating that the rotor of the motor has dropped back one pair of poles, with regard to the main generator, and then closing the switch when the motor is again in synchronism.

This may have to be repeated a number of times on some occasions, to bring the generator of the frequency changer sets to be paralleled in phase with the one that is running. It is a job that requires careful handling even for an experienced operator, because the machine drops out of phase at an increasing speed when the switch is opened, and by the time it comes into phase again, the hand on the synchronoscope may be moving quite rapidly. If the change is not made properly, the whole starting operation must be done over again.

When two alternating-current generators are paralleled, the indicator of the synchronoscope always swings to the zero point and remains rigidly in this position. One morning, however, after cutting in the motor of a 2000-kw. frequency-changer set, the indicator made several swings back and forth across the zero point before it finally decided to stay there. Nothing else happened and the machine kept on running, so I went ahead and cut in the generator. As luck would have it, the generator happened to be in phase, and it was not necessary to slip poles on the motor to get the latter in phase. When the exciting current of the motor was adjusted so as to maintain unity power factors, it required something like twice normal value.

I had always made it a practice to go up on the switch gallery and examine the high-tension switches as soon as possible after each operation. This is what probably saved trouble this time, as there was only a small fraction of a load on the machine and no doubt, under the conditions afterward found, as soon as load came on the machine would have pulled out of step. When I came to examine the switch, the cause of the trouble was at once evident. One of the wooden rods which closed the switch, there being one on each phase, had been broken; consequently, the motor was operating single-phase. As a temporary measure I took a stick and pushed the broken section into place, thus closing the third phase of the circuit. This made it necessary to reduce the exciting current for the motor to its normal value, to maintain unity power factor.

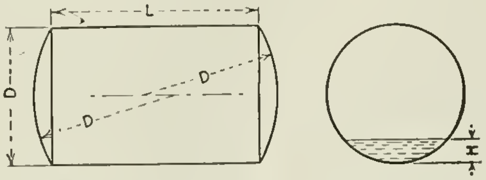
Calculating the Contents of Oil Tanks

There is a timely article in the Jan. 22 issue of *Power*, on the calculation of the contents of horizontal cylindrical tanks with dished heads, when the liquid is at different levels. The writer has no criticism whatever to offer concerning Mr. Strohm's method, which is the most logical way; but the time involved in getting up a table of capacities by that process is a nerve-trying ordeal—as the writer knows! It is evident that for the tank mentioned in Mr. Strohm's article it would be necessary to use the circular-segment formula forty-eight times, to obtain the volume at every inch of depth of the liquid for one-half of the tank.



DIMENSIONS USED IN FINDING CONTENTS OF TANK

The writer is employed by a large byproduct coke company, and the average plant of this nature has many storage tanks which must be calibrated and for which gages must be provided, so that the contents may be read at any time. He calibrated our tanks for a long time by the method given by Mr. Strohm, using a planimeter to obtain the areas of the segments, thus decreasing the labor somewhat. But our troubles came to an end when the writer discovered, in an old paper on chemistry, the formula,

$$V = 7.48D^2Lf_1 + 14.96D^3f_2$$

in which

V = Contents of tank in U. S. gallons at the depth considered;
D = Diameter of tank in feet;
L = Length of tank in feet;
H = Depth of liquid in tank;
f_1, f_2 = Factors whose values depend on the value of H, as shown in the table.

The meanings of the several letters may be more readily understood from the accompanying illustration.

VALUES OF f_1 AND f_2 FOR DIFFERENT DEPTHS

H	f_1	f_2	H	f_1	f_2
0.05	0.014681	0.00017	0.30	0.198168	0.01048
0.10	0.040875	0.00085	0.35	0.244980	0.01386
0.15	0.073875	0.00221	0.40	0.293370	0.01805
0.20	0.111824	0.00420	0.45	0.342783	0.02234
0.25	0.153546	0.00687	0.50	0.392699	0.02697

It should be noticed that the table gives the values of the factors only for every 0.05 of the diameter of the tank, whereas it is usual to calibrate tanks for each inch of depth. This difficulty can be overcome by calculating the capacities at all depths from 0.05D to 0.50 D, and then plotting the results in the form of a curve on cross-section paper, to a sufficiently large scale. The vertical scale can be used to represent depths and the horizontal scale to represent capacities in gallons. After the curve is carefully plotted, the capacity at any inch of depth may be read from the horizontal scale. By this means the formula need be used only ten times, instead of once for each inch of depth.

Pittsburgh, Penn. William C. Strott.

[From the sketch shown by Mr. Strott, it appears that his formula is strictly applicable only in case the radius of the dished head is equal to the diameter of the tank, although it will probably give results accurate enough for all practical purposes when applied to any horizontal cylindrical tank with dished heads.—Editor.]

Sucking from a Condenser

In the issue of Jan. 29, 1918, there is another letter [Others on pages 807, Dec. 11, and 740, Nov. 27—Editor.] on "Sucking from a Condenser," and I have read all the previous articles, but the matter was brought home by the same thing happening in the plant of which I have charge, breaking both steam valves of a Corliss engine. The circumstances as reported to me were as follows: The engineer had just shut off the steam to stop the engine, and was going around to the other side of the cylinder to shut the valve in the exhaust line between the engine and air pump or jet condenser, when there was a sound of water in the cylinder and a discharge of water from the relief valves. On examination I found both steam valves in eight or ten pieces each and the floor wet from the water, although it must have been twenty minutes after the accident before I got to the engine room.

The question is, Where did the water come from if not from the condenser? My conclusion, after studying the matter, is this: When this plant was built, the exhaust from the engine was dropped about 2 ft., then carried horizontally for about 15 ft.; there is a tee and two 45-deg. bends in this length; the condenser is connected to the tee, then it turns up with an elbow to the relief valve to the atmosphere. Now this pipe past the tee makes a dead end in which a certain amount of water is held by the exhaust from the engine; and when the steam was shut off, a few strokes of the pump cleared the engine of steam pressure, so that there was a partial vacuum as far back as the throttle valve, as the action of the piston would raise the exhaust valves off their seats and give the water in the dead end a surge or wave toward the engine—in fact, enough to carry it past the tee and into the engine so that the action of the piston would be as much of a vacuum pump as the pump itself.

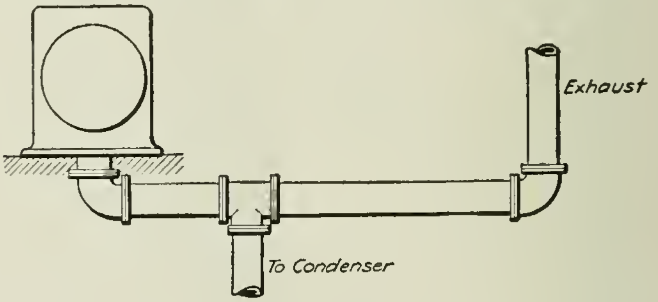


DIAGRAM OF EXHAUST PIPING

This is the second condenser that I have found connected in this way (off a tee). In the other case the condenser was condemned as "no good" until I changed it from the tee to the end of the pipe and put the relief valve on the tee; since then it has been working satisfactorily. The same change is required in this latter case, but the engine is used only in case of emergency and it is difficult to make the change, so it has not been done yet.

Telescopic-Oiler Discussion*

The discussion of telescopic oilers recently appearing in *Power* has brought out useful points. As H. Hamkens pointed out at the beginning of the discussion, the main disadvantages of most telescopics, especially the older ones, are too many parts, leakage of oil, tendency to irregular feeding and too rapid wear.

It is true that the older telescopics were somewhat complicated and that, with numerous springs, locknuts, washers, etc., they were hard to keep in repair and in good working order. But the design has gradually been simplified and improved until today oilers can be procured which are apparently as simple as it is possible to make them.

As Mr. Fenno pointed out in his article in the July 17, 1917, issue, the tendency to pumping and irregular feeding can be overcome simply by providing suitable clearance between the inner and outer telescopic tubes.

The rapid wear of the tubes noticed by Mr. Hamkens in some instances, is the result of their binding upon each other due to imperfect alignment either when installed or after reassembling. This can be avoided by due care when installing and, with some telescopics, extreme care when reassembling. It all depends upon the type of joint employed.

By employing the special design of true male and female joint shown in the illustration, all wear due to imperfect alignment, except that due to poor installation, is completely avoided, because no threading is even disturbed. Also, because this joint permits of gravity feed, the pumping tendency is practically, and leakage completely, eliminated.

With the arrangement shown by Mr. Fenno and illustrated in Fig. 1, the oil accumulated at the bottom of the outer element as at *A*. In other words, the flow of oil is against the direction of the joint instead of with it. Hence, the fiber packing *B* is always in contact with the oil and subject to deterioration and leakage.

In most of the older designs the joint could not be taken apart without first unscrewing the telescopic pipe. This meant that with any irregular alignment whatsoever in the initial assembling, the pipe would have to be screwed up to exactly its original position when reassembled, or extreme wear was sure to ensue.

With the type of joint shown in Fig. 2, both wear and leakage are practically overcome. The overhanging lip *D* drops the oil from the movable element *E* directly into the hollow of the fixed element *F*, and hence, unless the oil is fed in a flood greater than the latter can conduct it to the pin, the joint *G* remains leakless.

The joint is taken apart by sliding off the spring clip *H*, which is attached to the loose collar *I*. The movable element *E* then slides out of the fixed element *F*. As the construction at the top of the telescopic is similar, the telescoping pipes may both be removed without detaching them from their parts of the joints. Hence, they can always be replaced in alignment. As no nuts or screws are used in putting the joints together, they may be taken apart for cleaning or inspection while the engine is running unless the speed is uncomfortably high.

WILLIAM W. NUGENT.

Chicago, Ill.

Lime As a Protection for Steel

In the issue of Feb. 26, on page 301, there is an interesting letter by N. Bowland, on "Why Hot Water Pipes Pit," which gives as the reason for the rusting of steel and iron the unlike polarity of different parts of the material, setting up galvanic currents. To have a galvanic current requires, as is well known, an electrolyte, usually an acid, however weak, such as comes from vegetation sometimes and through the pollution of streams by sewage and the liquids from factories of different sorts.

In this connection I was led to the belief that if the solution was made alkaline there would be no electrolysis. To test this out, two pieces of commercial angle iron were cut from the same bar and placed in separate jars filled with river water, but to the water in one jar a handful of spent lime was added, while that in the other jar was left natural. Before immersing the two specimens in the water thus prepared, they were sandblasted to remove all mill scale and rust except one face that was left as it came from the mill and one face of each specimen, in addition to sandblasting, was polished to a fine surface. Both specimens were immersed in the jars on the same date, Oct. 2, 1915. The one in the natural river water began to rust immediately and is now covered with a thick coating, and much oxide has fallen off and covers the bottom of the jar. The other remains exactly as when put in. The polish on this specimen, immersed in lime water, is as perfect as on the day it went into the jar. The sandblasted side shows no rust whatever, but on the natural side there is one small speck about ⅛ in. in diameter which is brown in appearance, but there seems to be no appreciable increase in area or thickness of this brown spot from month to month.

This protective action of lime water is made use of by English hostlers, who are accustomed to take the highly polished steel bits from the horses' bridles when they come in from a trip and throw them into a bucket of lime water to prevent them rusting before they get time to give them their daily polishing. I find that lime water is effective in preventing rust in the bottoms of steel hulls, which nearly always have more or less bilge water in them, often from condensation of atmospheric moisture when there is no leakage. Whitewash is also an excellent preservative of steel in inclosed places like the air tanks in steel gates, where it effectually banishes rust and at a fraction of the cost of paint. It needs occasional touching up where condensation water drips from the top of the tank. It is a cheap remedy where applicable, but of course it will not stand abrasion or where the steel is under running water. It has been used for coating the tanks of the 50-ft. gates of the Mississippi River lock with the best of results. It seems to show that where the acid of the water is killed with lime, no electrolysis can take place.

The experiment is easy to make, but it seems not generally known what a good and cheap preventive of rust lime is when mixed with water. Readers of *Power* may find many uses for this simple protective and possibly someone may find a way to combine lime with a paint that will stick to the metal under water, making an ideal coating for steel.

Keokuk, Iowa. MONTGOMERY MEIGS.

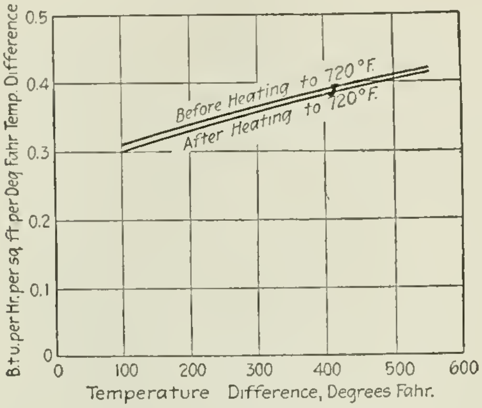
*See "Power" 1917, Jan. 30, p. 142; Mar. 6, p. 325; Apr. 3, p. 463; May 22, p. 707; May 29, p. 748; July 17, p. 96; Sept. 18, p. 399; Dec. 11, p. 806.

A Correction Regarding the Use of 85 Per Cent. Magnesia

In the May 1, 1917, issue of *Power* there appeared, on pages 593-6, a reprint of a report made by the Mellon Institute on heat-insulating materials. In both this report and in the editorial commenting thereon (page 604 of the same issue) statements regarding magnesia were made, which should be clarified and corrected, particularly as, in view of the present urgent necessity for conserving our coal supply, the true value of steam-pipe and boiler coverings for saving coal should be recognized and the proper use of such coverings encouraged. The editorial was partly rectified in the July 17, 1917, issue (page 90), but in view of the fact that reprints of the original article and editorial are being freely circulated, we desire to emphasize the true meaning of the original report.



CONDUCTIVITY OF MAGNESIA HEATED TO 720 DEG.

It was stated in the original that "even when subjected to low temperatures, it is only a matter of time before disintegration (of magnesia) takes place, as is well known from the behavior of magnesia coverings for steam pipes." And in the editorial this assertion was regarded as proved by the report, since the comment made was: "It is brought out that when subjected to low temperatures it is only a matter of time before disintegration of this material (magnesia) takes place."

The tests reported upon in the article cited were made for the purpose of determining the relative values of various refractory materials for furnace insulation, involving a set of conditions totally different from those for which magnesia is intended for use, conditions for which magnesia is admittedly unfitted. The high temperatures necessary in furnace practice are far in excess of those demanded by the highest steam pressures, even with a considerable degree of superheat in addition. It is well known that at a high temperature carbonate of magnesia loses combined-water and carbon dioxide, but this takes place at temperatures above 700 deg. F.

On page 594, in the article referred to, the statement was made: "It is well known that magnesia is equal in insulating value to many times its thickness in ordinary firebrick, so long as disintegration does not take place." We should like to restate this as follows: "It is well known that magnesia is equal in insulating value to many times its thickness in ordinary firebrick, when applied to temperatures suited to its use."

Magnesia is not a refractory; and the statement that disintegration of magnesia takes place at *low temperatures* refers to the temperatures of *furnace linings*, where 700 deg. F. might reasonably be called a low temperature. Such a temperature is much higher than magnesia, as a heat-insulating material, encounters in its regular day-in and day-out service. Even this temperature, however, can safely be used in steam pipes covered with 85 per cent. magnesia. In the accompanying diagram the upper curve shows the conductivity of a 2-in. thick magnesia covering before being subjected to a temperature of 720 deg. F. The lower curve was taken just after this test and shows that no damage was done to the covering but, on the contrary, that the thermal efficiency was slightly improved by the high temperature to which it had been subjected.

Pittsburgh, Penn.

Repairing Worn Valve Stems

I have had experience with worn valve stems on Corliss engines as referred to by Mr. Oakley in the issue of Feb. 12, page 230, and find that it is best to build them up by the oxyacetylene process and turn them to the original size in a lathe, making a mechanical job of it.

Sleeves may be all right when one knows just what the conditions are, but the next man that takes charge does not know what has been done. So, if the bracket is cut away, it means that if he orders new ones from the manufacturer they will not be of much use without a ring in the bottom of the stuffing-box to keep the packing in place; and it will also be necessary to have special packing for the stems with sleeves on, whereas one size should fit all four stems. J. B. Freeman.

La Grande, Ore.

Measuring High Pressures with Dead Weight

In my article, "Measuring High Pressures with Dead Weight," appearing in *Power*, Feb. 26 issue, at the bottom of Table II, on page 288, is a note which reads: "Fifteen pounds per sq. in. equals 30.35 in. of mercury; 1 in. of mercury equals 13.6 in. of water." This note should read: "Fifteen pounds per sq.in. equals 30.53 in. of mercury at 32 deg. F.; 1 in. of mercury equals 13.6 in. of water." Sanford A. Moss.

Lynn, Mass.

A Liberty Bond will soon become a badge of loyalty.

A Liberty Bond is a profit-sharing certificate on the prosperity of America.

A Liberty Bond is an old-age insurance policy, fully paid and nonassessable.

A Liberty Bond gives you a look into the future, but defeat in the war will tie you to an unfortunate past.

A Liberty Bond will pay you interest on the future of America. Defeat will make you pay compound interest on the future of Germany.

Inquiries of General Interest

Hotter Feed Water at Expense of Heating Capacity—We have use for all the exhaust steam from an engine that develops about 50 hp., but the exhaust-steam feed-water will not raise the temperature of the feed water higher than 200 deg. F. Would it pay to increase the size of the heater? K. R. R.

Where there is use for all the exhaust steam that is available, an increase of feed-water temperature would be of no benefit, for to accomplish the same heating by the exhaust as at present, the heat going to increase the feed-water temperature would need to be made up by live steam or some other source of heat.

Two Induction Motors on the Same Load—Is it practical to connect two induction motors on the same lineshaft where the load is varying? One motor is 300-hp. and the other 100-hp. capacity. G. C. T.

It would not be advisable to attempt to operate two motors of any type on the same load. If the machines are the same size and constructed to have the same characteristics, they probably would operate fairly satisfactorily. But when they are of different sizes or types, the probabilities are that one motor will take over more than its share of the load. This is readily understood when it is considered that one machine may take its full load at 5 per cent. and another at 10 per cent. decrease of speed.

Heating Surface and Grate Area for Steam-Heating Boiler—What number of square feet of heating surface and grate area should a boiler have for a low pressure steam heating apparatus to supply 1500 sq.ft. of direct radiating surface? W. B. C.

In estimating the required size of boiler, the number of square feet of direct radiating surface must be understood to include the surface of uncovered piping. Using good anthracite, or the better grades of bituminous coal, and with a good draft and usual frequency of firing, the boiler-heating surface should be equal to the total number of square feet of radiating surface divided by about 7.5 and the grate area should be equal to the total radiating surface divided by about 160. Hence for 1500 sq.ft. of radiation and pipe surface, the boiler should have about 200 sq.ft. of heating surface and 9⅓ sq.ft. of grate area.

Testing Out Correctness of Indicator Reducing Motion—How may it be determined whether an indicator-reducing motion is correct? E. T.

For determining the truthfulness of a reducing motion as used with a given indicator on a given engine, place the engine on a center, make a mark on the crosshead corresponding with one made on one of the guides and then turn the engine over to the other center and make another mark on the guide to correspond with the mark on the crosshead previously referred to. The distance between the marks made on the guide will be the length of stroke. Subdivide this distance corresponding to eighths of the stroke and, for greater accuracy, lay off sixteenths at the ends of the stroke, having all divisions so located that they may be matched with the mark on the crosshead for properly placing the crosshead and piston at the different positions they would occupy for the selected fractional parts of the stroke. With a spring in the indicator and a blank card on the paper drum, trace a long atmospheric line by drawing out the cord by hand. Then hitch the cord to the reducing motion and with the engine placed so the crosshead mark registers with one mark after another on the guide, raise the pencil arm of the indicator a short distance above the atmospheric line and obtain a trace for each position of the crosshead. If the reducing motion is correct, the distances between the tracings of the pencil will be in proportion to the corresponding fractions of stroke laid off on the guide.

Allowable Boiler Pressure for Stay-Bolted Water Leg—What would be the safe working pressure for the water legs of a locomotive type of boiler having plates ⅜ in. thick, with screwed and riveted stay-bolts ⅞ in. outside diameter, pitched 6 in. centers? F. R. B.

According to the A.S.M.E. Boiler Code, the maximum allowable working pressure for stayed flat plates should be calculated by the formula

$$P = C \times \frac{t^2}{p^2}$$

in which

P = Maximum allowable working pressure, pounds per square inch;
t = Thickness of plate in sixteenths of an inch;
p = Maximum pitch of stay-bolts;
C = 112, for stays screwed through plates not over $\frac{7}{16}$ in. thick.

By substituting,

$$P = 112 \times \frac{6 \times 6}{6 \times 6} = 112 \textit{ lb. per sq.in.}$$

Screwed stay-bolts ⅞ in. diameter, 12 threads per inch, would be 0.7307 sq.in. diameter at the bottom of the screw thread and have a net cross-sectional area of 0.419 sq.in. With an allowable load of 7500 lb. per sq.in., each stay-bolt would be capable of sustaining a load of 0.419 × 7500 = 3142.5 lb. The plate area occupied by each stay would be $(7/8)^2 \times 0.7854 = 0.6013$ sq.in. and the net plate area supported per stay would be $(6 \times 6) - 0.6013 = 35.3987$ sq.in. Hence the safe working pressure would be limited to the allowable working pressure for the stay-bolts, namely, $3142.5 \div 35.3987 = 88.7$ lb. per square inch.

Temperature of Steam After Passing Through Reducing Valve—If steam at 90 lb. gage pressure and 97 per cent. dry is passed through a reducing valve and the pressure is reduced to 5 lb. gage, what will be the temperature and quality? C. A. C.

According to the steam tables, the heat of a pound of dry saturated steam at a pressure of 90 lb. gage, or 105 absolute, consists of 302 B.t.u. in the water and 885.2 B.t.u. latent heat, so that if 97 per cent. dry, each pound of the initial steam contained $302 + (885.2 \times 0.97) = 1160.6$ B.t.u. In passing through the reducing valve, some heat is lost by radiation from the surface of the valve to the surrounding medium, depending on the character of insulation, but as loss of heat from friction is small, as the temperature within the valve is rather less than the temperature of the initial steam, loss of heat from radiation may be neglected; and as any work done on the steam in moving itself through the valve is restored when the steam is brought to rest, it may be considered that each pound of the steam after passing through the reducing valve, although reduced to the pressure of 5 lb. gage, contains as much heat as it contained in the initial condition, namely, 1160.6 B.t.u. Reference to the steam tables shows that a pound of dry saturated steam at 5 lb. gage, or 20 lb. absolute, contains 1156.2 B.t.u., hence each pound would contain $1160.6 - 1156.2 = 4.4$ B.t.u. in excess of the heat required for a dry saturated condition. Allowing the specific heat of superheated steam at the reduced pressure to be 0.48, the steam would be superheated $4.4 \div 0.48 = 9$ deg. F. As the temperature of dry saturated steam at 5 lb. gage is 228 deg. F., the actual temperature would be $228 + 9 = 237$ deg. Fahrenheit.

The Water-Power Bill

THE Administration's bill for the development and control of the water powers was referred to a special committee of 18, consisting of Titus W. Sims, Tennessee, chairman; Scott Ferris, Oklahoma; Asbury F. Lever, South Carolina; Frank E. Doremus, Michigan; Edward T. Taylor, Colorado; Gordon Lee, Georgia; Dan V. Stephens, Nebraska; John E. Raker, California; Ezekiel S. Candler, Mississippi; Carl Hayden, Arizona; John J. Esch, Wisconsin; Irvine L. Lenroot, Wisconsin; Gilbert N. Haugen, Iowa; Edward L. Hamilton, Michigan; William L. LaFollette, Washington; James C. McLaughlin, Michigan; Richard Wayne Parker, New Jersey; Sydney Anderson, Minnesota.

The week commencing Mar. 17 was set apart for hearings upon the measure. The bill, which has been considered in recent issues of *Power*, creates a commission consisting of the Secretaries of War, Interior and Agriculture and provides for the issue of licenses to those who wish to undertake the development of water powers upon navigable rivers or public lands for terms not to exceed fifty years. Rates and service will be regulated by the commission where there is no state regulation. The provision that the Government could take the property at the expiration of the license upon the payment of a "fair value not to exceed the original investment," which *Power* criticized in the original draft of the bill, has been changed so that the Government shall pay the "net investment of the licensee" as defined and interpreted in the Classification of Investment in Road and Equipment of Steam Roads, issue of 1914 of the Interstate Commerce Commission, plus similar costs of additions thereto and betterments thereof, minus the unappropriated surplus aggregate credit balances of current depreciation accounts, aggregate appropriations of surplus or income held in amortization, sinking fund or similar reserves or expended for extensions or betterments.

MR. MERRILL'S STATEMENT

On Monday O. C. Merrill, of the Forestry Division, one of the authors of the bill, presented a statement on behalf of its projectors. He showed that although there was a very considerable drop in the prices of material after the fixing of prices by the Government in 1917, prices still remained at the close of the year far above the pre-war level. Hydraulic machinery has advanced from 100 to 150 per cent. over 1914 prices; electrical apparatus, from 125 to 150 per cent.; steam-turbine generators, 150 per cent., and water-tube boilers, 170 per cent., with uncertain deliveries. The union scale of wages in classes of work found in power-plant construction has advanced in many cases from 25 to 40 per cent. since 1913. Operating costs have increased, owing to the higher prices of labor, maintenance, materials and fuel. Increased fuel costs have made the development of power by water increasingly desirable.

The demand for power has increased at an accelerated rate, until during the last two years the annual increment in power generated by commercial central stations alone has been from three to four billion kilowatt-hours, requiring an annual increase in installation of from one and one-half to two million horsepower. In the United States the kilowatt-hour output by central electric stations was 61 per cent. greater in 1917 than in 1914. During the four years from 1913 to 1917 the ratio of the operating expenses to gross revenue had increased from 62 to more than 68 per cent. The greater costs of construction and operation in connection with other demands upon capital make financing difficult. These conditions make water-power legislation that will offer capital a fair return and a certainty of tenure desirable.

Although new developments and extensions will be necessary to meet the demands of the immediate future, a considerable increase in the output of electrical energy could be secured by the combination of existing isolated plants into a single system through the medium of high-tension transmission lines. In 1912 the capacity load factor averaged only 26 per cent. for the United States and probably is not above 30 per cent. today. Eighty per cent. of the electric power development of Montana is in one system, and it has a capacity load factor of 58 per cent. Studies made in 1912 for New York City and Chicago showed that the consolidation of the operating stations in the latter city would have saved from $10,000,000 to $12,000,000 in investment. In New York it would have saved from $18,000,000 to $20,000,000 and would have reduced operating expenses by $1,000,000 a year.

EXTENT OF WATER-POWER RESOURCES UNKNOWN

Nobody knows whether our water-power resources are 30 million or 300 million horsepower, or what is the relation of the powers to any particular market. An intensive study should be made of the conditions and possibilities. The bill coördinates the activities of the three departments that have to do with water power. Our industrial efficiency both during the war and thereafter will be increased or diminished according to whether we do or do not make adequate provision for the development of our water-power resources. Water-power legislation should be considered a war emergency measure and as such should be taken up by Congress and passed at an early date.

Following the presentation of his formal statement Mr. Merrill was questioned by members of the committee, remaining upon the stand all day Monday and Tuesday forenoon. He was interrogated principally on the following phases of the bill: Licenses, rentals, rates and rate regulation, and recapture of project. His replies brought out the following points:

The terms of the license should be absolutely definite and unchangeable for the entire period of issue. This is quite necessary in order to prevent any uncertainty in the mind of the licensee as to the conditions under which he can operate. It would be inadvisable to introduce any factor that would make the terms of the license subject to change. One member of the committee suggested that the term of the license should be for an original period of 50 years "unless the applicant should request and the commission agree upon a shorter term."

It was suggested that the application by the licensee for a new license should antedate the expiration of his original license by a definite stated period of time, which should be long enough to permit the delivery of a new license on the expiration of the old one. There was considerable discussion on the tenure of the license, but it was Mr. Merrill's opinion that the original term should be for 50 years and that any unusual conditions should be met by an adjustment in the rental charge.

RENTAL CHARGES NOT FOR REVENUE PURPOSES

Mr. Merrill felt that the rental charge should apply to the total capacity of the project and not to production only. While the rental would not have much to do with encouraging or discouraging the development of a project, yet any effect which it might have should be in the direction of securing maximum development. The idea of the rental charge is not to secure revenue for the Government, but it is made in return for the issuance of a license. The money thus received is to be used (1) to defray the cost of administration and (2) the possible necessity of recovering excess earnings which it is impossible to reach in any other way.

While the rentals should be nominal, they should be greater in those cases where the Government contributes land or some other tangible property to a project, and less where the Government has nothing to offer but the license. Whatever provision is made should be clearly stated in the license before it is accepted by the licensee. It was Mr. Merrill's opinion that it would be a better fiscal policy to charge a rental that would be nominal and that would not reduce earnings below a fair return or increase rates to the consumer. As between getting revenue for the Government and reducing rates to the consumer, rental charges should operate in favor of the latter.

Rate regulation on interstate business should be left to the several state authorities and handled locally as long as local authorities show the ability to act and as long as there is no disagreement between states. Federal jurisdiction should come in when other authority is insufficient.

The recapture clause is considered to be the most important in the bill, and it was Mr. Merrill's opinion that the basis for recapture should be an actual legitimate original cost of the property plus additions, less any funds accumulated in unappropriated surplus, depreciation and amortization. The price should allow nothing, however, for any unearned increment in value of the property, good will, going value or expected profit.

Judge Raker, of California, was solicitous regarding the effects of the measure upon the use of water for irrigation purposes.

Chairman Sims said that the Government was concerned with projects upon navigable rivers simply as means for improving navigation. A 10-ft. dam might effect this purpose, but a licensee might put up a 50-ft. dam in order to get the power byproduct. In case the Government recaptured such a project, could it operate it as a power plant and enjoy the returns from the greater investment? In other words, can the Government, under the Constitution, go into the power business? Mr. Merrill could not say. We do not know what the powers of the Federal Government may be fifty years from now.

Henry J. Pierce, of Seattle, told of a $25,000,000 project in which he was interested at the Priest Rapids on the Columbia River. It would make the river navigable from its mouth to 200 miles above the rapids, nearly to the Canadian border, develop 250,000 horsepower at the lowest flow of the river and as much again or more during the season of high water. This season of surplus power synchronized with the irrigation demand, and the extra power could be used to pump water to arid lands above the watered level. He thought that in the granting of licenses preference should be given to those who were already in the business and best qualified to carry out the development.

Calvert Townley, assistant to the president of the Westinghouse Electric and Manufacturing Co., although anxious in the interest of his company, which furnishes machinery for hydro-electric installations, to see the water powers developed, was a bear on the value of such projects, claiming that there were few water projects that offered much of an advantage over steam-operated plants. For this reason the Government should not encumber the privilege with onerous restrictions.

Public Interest Should Be Protected

E. K. Hall, vice president of the Electric Bond and Share Co., spoke for the investor. The interest of the public, he said, is to get the water powers into use. The first thing in any bill is to protect the public interest. Rates and service should be regulated through state or some Federal commission so that it will be certain that no unreasonable profit shall be made. But in order to interest capital the interest of the investor must also be protected. A hydro-electric development calls for a tremendous investment, with a very short tenure of the title and a very slow turnover. The money to build the public utilities of the country comes from small investors. From the point of view of the investor there are two fundamental defects in the bill. The contract has been made definite, and the investor knows what he is getting and what is expected of him. He is assured of the enjoyment of the privilege for fifty years and of the return of his capital at the end of that period if the Government at that time wishes to recapture the project. But if the Government does not want to take the property, he must continue to run it under an indeterminate and uncertain tenure. He cannot issue refunding bonds, because he does not know how long he may be allowed to hold the property. For this reason Mr. Hall urged that if the Government did not wish to take or transfer the property on the expiration of the license the license should be reissued to the holder for a term of thirty years.

The other defect was the provision that the Government could acquire the property at the expiration of the license on payment of the net investment. This assured the investor the return of what he had put into the project and had not already taken out besides his fair profit, but did not allow him to profit by the enhanced value of the property. In all other businesses the investor was allowed, besides what fair current profit he could make, to benefit by an increase in the value of the property while in his hands. In response to an inquiry by a member of the committee, he said that he considered this the best bill offered to date.

On Wednesday morning John A. Britton, vice president and general manager of the Pacific Gas and Electric Co., told of two projects in which his company is interested—one at Lake Spaulding and one on the Pitt River—which would be affected by the pending legislation. The company owned or controlled practically all the land, but in one case the pipe line would have to pass for a short distance through a portion of the forest reserve, and in the other case about 36 acres of Government land would be subjected to occasional flooding. It did not appear just, on account of these minor concessions, that the whole great project of which they were such an inconsiderable part should be brought under the provisions of the act, and he suggested amendments whereby such minor concessions might be granted upon a lease basis. He also suggested limiting the rental to not more than 50 cents per annum per horsepower generated. The bill provides that the president may take the plant for war purposes, and upon restoring it shall pay such just and fair compensation for its use as may be fixed by the commission upon the basis of a reasonable profit in time of peace. Mr. Britton pointed out that such a settlement would not recompense the company for the loss of customers driven over to competitors or for the investment in other plant necessary to hold them, and urged that this be made to read, "shall pay to the party or parties entitled thereto just and fair compensation for the use of the property."

Indeterminate Franchise with Investment Return

In response to an inquiry of a member of the committee as to how he would regard an indeterminate franchise with a guarantee of the return of the investment in case of recapture, he answered that that was just what they wanted. With these amendments the bill is the most workable bill that he has ever seen. Asked by Representative Taylor if he knew of any water-power trust interlocking directorates or combination of interests, Mr. Britton said that he could speak only for California, but there was nothing of the kind evident there. Even if there were, with the present method of rate control and regulation it could not be made onerous upon the consumer. Every public utility ought to be a regulated monopoly.

Chairman Sims asked what would happen if at the expiration of the license there were no other applicant, and the Government must either take the plant over, involving a large appropriation, or allow the licensee to continue, the licensee would not be in a position to dictate terms to the Government. Mr. Britton's reply was that with the present tendency of public thought, at the end of fifty years it would be no shock to the public if the Government took over and operated the plant itself. To Mr. Sims' urging that the money would have to be appropriated, Mr. Britton replied that it would be paid for a going concern and immediately begin to return a revenue under which conditions public and congressional approval of the appropriation would not be difficult to obtain.

The chairman thought that it would be impossible to obtain the appropriation of such large sums and that therefore the license would be in effect perpetual. Mr. Britton thought that the Government would be glad to recapture the project and turn it over to the municipality that would have grown up around it. The most that the original grantee can make is a reasonable return. If he makes a paying concern out of it, the Government can take it when the license expires. If he does not make good, the Government can leave him in his misery.

Asked whether this bill or the Shields bill, both unamended, was the better, Mr. Britton replied that in his opinion the bill under discussion by the committee would be the most attractive to capital.

H. T. Freeman, of Hartford, of the Connecticut River Co., said that his company in the first half of the last century had put a dam in the Connecticut River by the consent of the state legislature, before the Federal Government had begun to exercise control in such matters, and urged that the provision under which the commission might grant licenses to parties operating projects upon public lands or navigable rivers "under authority heretofore lawfully granted" might be so modified as to include such a case. He also argued for "just compensation" instead of return of net investment as the condition of recapture. .The bill excludes as an element in determining cost, expenditures from funds obtained through donations by state, municipalities, individuals or others. Mr. Freeman said that in some cases customers paid for extensions of lines necessary to furnish them power, and it was explained that if the company eventually reimbursed the customer and acquired the line it became a proper element of cost, but if it involved no expenditure by the company it could not be so included.

The first excess-profit act ever passed in New England gave his company the right to make 8½ per cent. on its investment, after which the Government took 8 per cent. and any excess was divided equally between the company and the Government.

To Mr. Taylor's inquiry as to whether there was any water-power trust in New England, Mr. Freeman replied that on the contrary there is the fiercest kind of competition.

John J. Harris, of Hardin, Mont., president of the Big Horn Canyon Irrigation and Power Co., described the project in which he was interested and claimed that the Government would receive a benefit from it in flood control equivalent to what it received in improved navigation on navigable rivers and that this benefit ought to be considered in fixing the rental charge. Three years is not enough time to do the preliminary work. He was still presenting his case when the committee took a recess until Thursday morning.

THURSDAY MORNING'S SESSION

On Thursday morning Charles N. Chadwick, chairman of the Committee on Conservation of State Waters, Lands and Forests of the Chamber of Commerce of the State of New York, appeared in behalf of House Bill No. 9681. This bill seeks to create a national board of water conservation consisting of seven members appointed by the President by and with the advice and consent of the Senate, not more than four to be members of the same political party, each to be a citizen of the United States, and none to hold any other Federal, state or municipal office. They are to be appointed for seven-year terms so that the term of one commissioner will expire each year, and are removable only for incompetency or misconduct.

This board would have the control and the jurisdiction of the interstate waters of the United States. It would ascertain what are the interstate streams of the United States most available, desirable and best for development, control and jurisdiction, and study the problems relating to the conservation of the rainfall, the control of freshets, recovering desert and waste lands by irrigation and swamp lands by draining, and the pollution of interstate rivers; the utilization of the rainfall for potable purposes and for navigation and water transportation aided by storage reservoirs, regulation of stream flow and waterways, and for the development of hydro-electric and other power, and the control thereof. It would study the climatic conditions of the state and compile information and make recommendations concerning the revision and codification of the water laws and the passage of new laws coördinating Federal and state jurisdiction. It would make surveys, maps, plans, specifications, estimates and investigations with regard to interstate streams, and report to Congress with recommendations as to what action should in its opinion be taken with reference thereto.

Mr. Chadwick explained that interest has been centered upon the one problem of hydro-electric development, while the bill in favor of which he appeared dealt with the conservation and utilization of the rainfall for all purposes. The broad policy of the nation with regard to the disposition and use of its rainfall for various and conflicting purposes could not be determined by busy and transient cabinet officers but required the concentrated and continuous attention of specialists. The single executive provided for by the Administration Bill could not, single-handed, deal with the determination of the national policy in all phases of the question, and cabinet officers would become but rubber stamps for his recommendations. He doubted the constitutionality of that provision of the Administration Bill which conferred the right of eminent domain upon the licensee. Under it a licensee might condemn even municipal or state property, and the taking of private property for private use cannot be justified by a declaration of beneficent purpose. Under the Administration Bill there is likely to be a conflict of authority between state and Federal Government. There is also the question of riparian rights vs. rights of appropriation for beneficial purposes. In the East, with its congested population, the large question is the use of the water for potable purposes; in the West, with its large arid sections, that for irrigation. The commission should be composed of big men who will put in all their time, and the bill should be so drawn that they can deal with the whole, broad, general question.

Mr. Anderson, of the committee, pointed out that under such a bill each project would require an act of Congress.

Judge Raker, of California, evinced a live interest in the irrigation phase of the question and asked if the witness considered hydro-electric power as secondary to the other uses. Mr. Chadwick replied that the use for potable purposes should come first; next commercial uses, then navigation, and then hydro-electric.

CHADWICK BILL SAME IN SUBSTANCE AS ADMINISTRATION BILL

Mr. Chadwick admitted that in substance his bill was the same as the Administration Bill, with the exception of the personnel of the commission. But, under his bill, the commission would not be subject to the will of one man who could reverse the policy of the country with regard to the administration and utilization of the rainfall.

C. F. Kelley, counsel for the Montana Power Co., said that the bill, though a compromise, appeared to afford a workable measure. He said that the bonds should be amortized within the duration of the original license, and stood out for "just compensation," instead of a return of the "net investment," as the condition of recapture. He agreed that unappropriated surplus accumulated from earnings in excess of a fair return on the investment should be deducted in computing the net investment, but claimed that such portion of such funds as had been reinvested in improvements and betterments should not be so excluded. He claimed that inasmuch as the prospective applicant would be at great expense in making surveys, maps, plans, etc., a preliminary permit should be exclusive to its holder. Section 8 provides that any successor or assign of the rights of a licensee shall be subject to all the conditions of the license under which such rights are held by the licensee. Mr. Kelley suggested that such conditions may have been so onerous as to have led to the failure and foreclosure of the operation under the original license, and that there should be some arrangement whereby they might be modified with the transfer of the license. He thought that the provision that the licensee shall convey to the United States free of cost its lands and rights-of-way, and right of passage through its dams or other structures, as might be necessary to complete navigation facilities, would be likely to be burdensome. The repealing clause stipulates that "no alterations, amendment or appeal shall affect any license heretofore issued under the provisions of this act, or the rights of any licensee thereunder," which language unwittingly shuts the license off from desired modification. Mr. Kelley therefore suggested the insertion of the word "adversely" before "any license."

Chairman Sims said that upon the expiration of the license the Government had three alternatives—to continue the license in the hands of the original licensee, to transfer it to another licensee, or to take the plant over. Unless the Government had some use for it for a strictly Governmental purpose, it would not take it over. And if nobody else wanted it, there would be no alternative but to leave it in the hands of the original licensee, and that upon his own terms, so that the grant was virtually one in perpetuity.

Mr. Kelley thought that renewals and replacements were not properly taken care of in the depreciation charge, and that there was likely to be a conflict between public officials that will be zealous in protecting the public interest and the building up of a surplus. The question of what is a fair return cannot be decided at the time of granting the license, and at the end of the term a manager who thought he had a comfortable surplus for distribution to his shareholders might find it wiped out entirely upon the ground that it had been earned by charging a rate which would yield more than a fair return. No other class of property is subjected to such "discrimination." There is no limit in the bill to the reserve fund that a promoter may be required to maintain. It is not quite clear in Section 5 just what rights are conferred upon the holder of a preliminary license.

Asked if he would give a municipality a better rate than another consumer, Mr. Kelley answered that in case there were a limited amount of power available he would give a municipality the preference as to service, but at the same rate.

Mr. Ferris, of the committee, pointed out that an amortized concern could keep going very cheaply. Mr. Kelley said that the tendency in all public utilities is to increase the amount of business done by decreasing the rate, and so to make more money. Further, he thought this bill more workable than any of the others which had been offered, and he would sooner see it adopted than none.

Miss Rankin, member of Congress from Montana, asked the witness about interlocking directorates, but obtained no admission that the Montana Power Co. was so interconnected with other interests. In reply to a question by Judge Raker as to price and service to small consumers, Mr. Kelley said that there was more power developed per capita in Montana than in any other part of the United States, and that the rates were the lowest. He said that he did not know of any water-power development in the United States that was paying more than 5 per cent. dividends. He justified the common stock, usually referred to as water, as a just return to the promoter for his enterprise.

Mr. Stuart's Paper

Charles E. Stuart, of the United States Fuel Administration, read a short paper dealing with the efforts of the Administration to conserve fuel, and suggested, as possible aid by the Government in this direction, assistance which may be rendered to the power system wherever interconnections may be deemed practicable and desirable, the rendering of financial aid for the enlargement of central-station systems to produce increased power, a radical fuel saving, or where there will be obviated what practically amounts to a duplication of investment, as in the case of the construction of isolated plants at this time; the necessary help to enable the complete systemization of the power situation of the entire country, the avoidance of duplication of investment, and the establishment at some centralized point, as at Washington, of a complete perspective of the entire power situation which would prevent any of the now recognized errors or abuses, such as exist in the duplication of investment.

John J. Harris, of Hardin, Mont., President of the Big Horn Canyon Irrigation and Power Co., resumed the stand to describe some of the preliminary operations which were necessary in working up a project of this kind.

A. P. Morrison, of the Electro-Metallurgical Co., Niagara Falls, spoke from the point of view of the user of power, to whom stability of service and of rates was of the first importance. While he is apparently taken care of by the public service commissions, the fact that his investment is entitled to protection against increase of rates or diminution of service has not been given the importance that it warrants. The investment of the user of power is greater than that of the furnisher of power. No power can be developed on a franchise revokable at will, and a revokable contract is of no use to the user of power. He suggested an amendment to the bill to prevent existing projects coming in under the law to get a chance to raise rates.

Commenting upon Mr. Kelley's testimony that a project should be amortized within the life of the license, Mr. Pierce said that the Priests Rapids development could not be developed under a law that required its amortization within 50 years, and in his opinion 95 per cent. of the available water powers could not.

S. P. Weston, representing the Water Power Legislation Committee of the American Newspaper Publishers Association, also questioned Mr. Kelley's position upon the question of amortization, and said that English companies always differentiated between stock and bond capital. He showed that the available paper-pulp material outside of private ownership in the United States was in the Western States contiguous to the undeveloped water power necessary for its manufacture. He was personally interested in a project which had obtained contract for $75,000,000 worth of print paper, but was unable to finance it on account of the Supreme Court decision in the Utah case.

A discussion ensued with regard to the provisions of recapture, and Mr. Ferris, of the committee, said it appeared that the Government would either have to take the projects over, or allow them to go on. It was practically a mandatory proposition. An inquiry by Representative Lever as to whether, in the opinion of the witness, the present tendency is not in the direction of Government ownership, was followed by a speedy adjournment.

Possible Conflict with State Laws

Augustus H. Houghton, representing the Conservation Committee of the State of New York, called attention to certain possibilities of conflict with the New York State laws, and suggested amendments which would avoid these. The term of five years provided for the executive was too short. It ought to be ten or fifteen years at least. Asked by Representative Taylor why the state had not gone about developing its water powers, the witness replied that the present commission does not believe in the state going into business and competing with existing companies.

William B. Matthews, of Los Angeles, which has its own municipal plant, believed that a license to a state or municipality should be perpetual, where the United States does not wish to take it back. The commission should not have jurisdiction or regulation over the rates and service of a municipal corporation, where the power is used for state or municipal purposes. He believed that the proposed law should not only give encouragement to private capital, but to states and municipalities. It is not likely that the National Government will be disposed to recapture and operate the project itself, and that a license once granted to a private corporation will be in effect perpetually. Under this condition, which would not be compatible with the public interest, the project should be recaptured and given to the municipality, or the municipality should have a prior right to it.

A few other witnesses remain to be heard, but the bill as a whole appears to meet with general commendation, and there is every evidence that it will be reported favorably without radical changes. How it will be received by the Senate, which has already passed the Shields Bill is not so evident.

The Netherlands Government has fixed maximum prices for coal and coke, says *Commerce Reports*, which are an advance on previous prices. They are stated in florins per hectoliter, but in American terms are equivalent to about $22 a ton for anthracite and $17 for bituminous coal; coke, about $10 a ton; coal briquets, about $25 a ton. The distribution is carefully regulated by cards in specified quantities, varying with the size and nature of the residence or the place of business. The quantity allowed, especially to residences, is much smaller than the amount they consumed in peace times.

John P. Sparrow, Dead

John Porterfield Sparrow, chief engineer, New York Edison Co., and for many years a member of the American Society of Mechanical Engineers, died at his home in Flatbush, Brooklyn, on Mar. 18, 1918. He was born in Portland, Me., Mar. 17, 1860; he died therefore at the age of fifty-eight.

Mr. Sparrow was an engineer by inheritance and education, his father, John Sparrow, being well known in the engineering field. His early education was obtained in the public schools of Portland, but this was largely supplemented by his father's teachings in physics, chemistry and engineering. In 1879, being interested in sugar manufacture, he was taken to Europe by his father to study the industry, and while there visited all the larger engineering works.

JOHN P. SPARROW, FOR MANY YEARS CHIEF ENGINEER, NEW YORK EDISON COMPANY, WHO DIED OF PNEUMONIA AT HIS HOME, BROOKLYN, N. Y., MONDAY, MARCH 18. MR. SPARROW HAD CHARGE OF THE DESIGNING AND BUILDING OF THE FAMOUS WATERSIDE POWER STATIONS. BESIDES HIS MANY CONTRIBUTIONS TO ENGINEERING, HE WAS A PHYSICIST OF NO MEAN ABILITY, MADE VALUABLE INVESTIGATIONS INTO THE MICROSTRUCTURE OF THE NONFERROUS ALLOYS AND DID MUCH PIONEER WORK IN COLOR PHOTOGRAPHY.

In 1880 he entered the Portland Co.'s locomotive and marine engine works as an apprentice. He served his apprenticeship and became a toolmaker and erector for that company, leaving it in 1888 to work for the Sprague Electric Co. During the next two years he acted as superintendent for the Sprague company in charge of construction of electric railways in the various parts of the country.

In 1890 he went to New Orleans for the New Orleans Electric Co. on construction work. In 1892 he joined the construction staff of the Edison General Electric Co. and was employed in building lighting and power plants for them and the Canadian General Electric Co. until 1895. He then joined the staff of the Construction Department of the Edison Electric Illuminating Co. of New York, and in 1898 became superintendent of construction, having charge of all the construction, which included the new Waterside Station, at that time the largest and most important construction of its kind which had been attempted. In 1906 he became chief engineer of The New York Edison Co. in charge of construction and operation, the position he held at the time of his death.

Mr. Sparrow became a member of the American Society of Mechanical Engineers in 1898, and has been an active member serving on various committees. At the time of his death he was chairman of the Committee on Standardization of Flanges and Pipe Fittings and had just finished the completed report on that subject. On Feb. 1, 1918, he was appointed chairman of the Advisory Board of the Power Test Committee. His work along these lines has been particularly valuable as his long experience, trained judgment and personal influence insured the reconciliation of conflicting interests.

In the Association of Edison Illuminating Cos. he was a member of the Committee on Steam Plants from 1906 up to the time of his death, and was chairman in 1910, 1912 and 1913. In this work his most valuable contributions were those in connection with coal testing and burning. Before the Edison Association he presented a number of papers on boiler-plant problems.

In the National Electric Light Association he was a member of the Committee on Prime Movers for a number of years.

Shortly after the United States entered the war, he made a number of tests for the Naval Consulting Board in connection with smoke abatement on ships as a protection against submarines.

Mr. Sparrow's hobbies were largely of an engineering character. In photography his work as an amateur rivaled that of many professionals, and he was one of the first to take up color photography. Microscopy, as a result of his early training, was always one of his chief aids, and his work on the photomicrography of lamp filaments is well known. In later years he turned to metallography in connection with the ever-present subject of the corrosion of condenser tubes, and assisted in the settling of important questions of heat treatment in the manufacture of this material. His knowledge of physical science was fundamental, and he was an adept in the mechanical handling and manipulation which is a necessity in research work of this kind.

Mr. Sparrow had a charming personality and his optimistic temperament, uniform courtesy and entire absence of contentiousness endeared him to a host of friends. He was held in affectionate regard by the officials of The New York Edison Co. to whom his passing away comes as a personal loss.

Struggling with Poor Coal*

By George E. Wood

Mechanical Engineer, Connecticut Company

The Connecticut Co. has six generating plants ranging in capacity from 16,500 kw. to 350 kw., which supply the entire system with energy, with the exception of the New Britain, Waterbury, Norwalk and Stamford divisions, the latter sections being supplied with purchased power. The total installed capacity is 40,000 kw., of which 12,000 kw. is held in reserve. The Bridgeport, Hartford and New Haven plants supply 85 per cent. of the total output.

Since the latter part of 1916 the quality of the coal has been gradually deteriorating and at present it is a continual struggle to keep the plants operating, to say nothing of trying to improve the efficiency. If good coal could have been obtained last year a 10 per cent. increase in efficiency over 1915 would have been attained in fuel consumption, due to new and reconstructed plants. However, as the fuel was below standard, the actual tonnage consumed increased 24 per cent. over that required in 1915 and 31 per cent. over what would have been required in 1917 with standard-quality coal. It appears that with good-quality coal 7 per cent. less cars would be required on the railroads compared with the rolling stock needed to handle what one of the company's engineers terms "black asbestos."

Soon after the first lot of poor coal was received the tonnage consumed began to rise. The company engaged the services of a competent combustion engineer, who instructed the various boiler-room engineers in the vagaries of combustion under the conditions attending the constantly changing grades of coal. Without his aid the tonnage consumed would have been considerably greater.

Plants Were Designed for High-Grade Fuel

It is possible economically to consume low-grade fuels of uniform quality and corresponding low price, where the furnaces are designed to suit the fuel, with ash-removal machinery capable of meeting the heavier demands and, of course, suitable unloading facilities. When, however, a plant is designed for a high-grade coal and the fuel actually used is worse than a uniform low-grade product, there is no doubt as to what the results will be. Thus, one consignment of fuel received would pack down on the tuyeres so solidly that the combined capacity of all the blowers in the plant could not force sufficient air through to allow it to burn. To attain any semblance of combustion, it was necessary to apply slice bars through the observation doors, and even then interruptions of varying duration could not be avoided.

About the time this coal had been "run through the furnaces" and the firemen were able to attain better results, the next shipment would be received. As this new coal followed the last of the previous shipment through the bunkers, the firemen would find that with the usual plenum in the wind boxes, the coal would be blown over onto the dump plates and pile up in a red-hot mass to a depth of three to four feet. Often the entire dump plate and shaft twisted out of shape so badly that they had to be entirely renewed. Within a few days some coal was received that would burn nicely for about an hour, after which it could be seen gradually to shut off the air supply. The shaking grates could not be moved more than one-half inch, and a slice bar thrust in along the grates would lift nearly half the fire up from the grate. Steam jets in the ashpits were of little assistance in preventing this "india rubber" like clinker, and after a short time the plant was shut down for two hours. Section breakers and feeder switches were relocated to relieve the load on the plant, and the arrival of more coal made it possible to resume operation under these conditions. It also gave the operators a chance to take the boiler out of service and clean the heating surfaces, which were covered with soot and slag.

This boiler had been in service continuously for three weeks and as a result of the cleaning five barrows of stalactites were taken out, in spite of the fact that the boiler was dusted daily. If the boiler had not been taken out of line at the time, a deposit would have formed which practically would have closed the gas passage.

An investigation of the records of fuel analysis shows samples containing 24 per cent. of volatile hydrocarbons, 45 per cent. fixed carbon, 29.8 per cent. ash and 3 per cent. sulphur, with a calorific value of 10,300 B.t.u. per lb. One particular cargo "passed through the furnace" with the ash running close to 37 per cent. by weight. The average for all coal received in 1917 was but little better than the case cited.

Poor Coal Increased Maintenance

In addition to serious interruptions, great trouble has been experienced from stoker failures. These occur at some plants at the rate of two a day, and on this account it is impossible to repair them in a first-class manner. This is not to be wondered at when one stops to think of the foreign substances found in the coal, such as traprock, short bolts, coupler pins, slate, slag, brickbats and even pig iron. The smaller pieces pass through the crushers and into the furnaces, in spite of the vigilant eye of the weigh-hopper man, and then there is a cracked bearing cap, broken bracket or sprung crankshaft. Stoker repairs are tripled, and the stock of repair parts seriously depleted.

The poor quality of coal has added to the difficulties of the labor situation. It has been particularly difficult to retain the ashmen and firemen. For every carload of ashes taken out of the ash hoppers during 1915 three carloads are taken out today.

An inspection of the operating records shows that the total unit cost of production for 1917 was 1.48c., or double the cost for 1915. Of this, 82.5 per cent. is due to fuel cost. Comparing the total amounts for the fiscal years 1915, 1916 and 1917, the total cost of production for 1915 was $630,000; for 1916, $745,000 (an increase of 18 per cent. for 8 per cent. increase in production), and in 1917, $1,187,500, an increase in production of 11 per cent. and a cost increase of 90 per cent. In 1915 the total amount paid for fuel for the six plants was $425,000, or 67 per cent. of the total production cost. In 1916 it was $520,000, or 70 per cent., and in 1917 it was $976,900, or 83 per cent., which is more than twice that paid under normal conditions. Labor shows an increase of $33,000 and maintenance an increase of $70,000. It is not unreasonable to state that fully 90 per cent. in the company's increased cost of power is due solely to the fact that the road is paying for, but not getting, coal.

Company Plans Additional Equipment

Several plans are afoot to relieve conditions in the near future. The most important is the installation of additional ash-handling facilities and coal-handling equipment and storage space. In the last case it is proposed to discharge sufficient coal at each plant between the dates of Apr. 1 and Nov. 1, 1918, to take care of the needs during this period and have stored at the latter date sufficient coal to carry the plants through until the spring of 1919. To do this it will be necessary to receive in 214 days 150,000 gross tons of coal, which is equivalent to unloading 692 tons per day. To attain this result the Connecticut Co. will have to expend between $200,000 and $300,000. For the New Haven power plant it will have to furnish additional storage space. In the Hartford plant the same thing pertains, and in the Bridgeport plant another dock will have to be built, with facilities for reclaiming the coal and getting it into the bunkers. To put in this coal and get it into storage about $500,000 will have to be expended. A quotation received in this connection for an eight-wheel locomotive crane with 50-ft. boom and a 1½-cu.yd. bucket was $18,458, compared with $7,650 in 1915. This plan will relieve much anxiety as to coal shortage next year and will relieve traffic congestion.

The company has exerted every effort to reduce fuel consumption to a minimum. Strict attention has been paid to turning off all unnecessary lights and electric heaters; the skip-stop system of operation has been inaugurated; a vigorous campaign in power saving has been instituted with good results.

---

*Abstract of address before New England Street Railway Club, Boston, Feb. 18, 1918.

The National Chamber of Commerce Vote on the Water Powers

1. That Federal legislation encouraging the development of water powers should at once be enacted. Adopted by the almost unanimous vote of 1324 to 6.

2. That authority to grant permits should be vested in an administrative department. Carried by a vote of 1253 to 17.

3. That the permit period should be at least fifty years, any shorter period being at the applicant's option. In favor, 1216; opposed, 42.

4. That tolls should attach only to use of public lands or benefits derived from headwater improvements. Adopted by vote of 1191½ to 40½.

5. That permittees should be entitled to acquire the right to use public lands forming only a small and incidental part of the development. Carried by a vote of 1210 to 25.

6. That recapture should be exercised only upon payment of fair and just compensation. In favor, 1234; opposed 25.

7. That if recapture is not exercised, the investment of the permittee should be adequately protected. Adopted by a vote of 1226 to 26.

8. That rates and service should be regulated by state commissions where the service is intrastate, with Federal regulation only where several states are directly concerned and do not agree or there is no state commission. Carried by a vote of 1177 to 57.

9. That if any jurisdiction to regulate the issuance of securities is exercised, it should be solely by the state. In favor, 1114; opposed, 117.

10. That no preference should be granted as between applicants amounting to a subsidy from the government creating unequal competition. Adopted by a vote of 1191 to 38.

Navy Engineers to Train at Stevens

The Navy Department, after consultation with President Humphreys, has designated the Stevens Institute of Technology, Hoboken, N. J., as the headquarters for the new United States Naval Steam Engineering School for training engineer officers for the Naval Auxiliary Reserve.

This school is the only one devoted to training engineer officers for steam-engine service, and is a branch of the large training school now located at Pelham Bay Park, New York. There is at Pelham, in addition to the school for general training of enlisted men, an Officers' Material School, Naval Auxiliary Reserve. Both the school at Pelham and the engineer officer school at Stevens are under the supervision of the supervisor, Naval Auxiliary Reserve. The education of the engineer officers at Stevens is directed by Prof. F. L. Pryor, of Stevens, who has been appointed by the Navy Department, with the approval of President Humphreys, civilian director.

It is contemplated to make a five-months course for the training of an officer; one month to be devoted to military and ship duties training at Pelham, one month at Stevens to receive the preliminary requirements and duties of an engineer, one month in inspection and repair duties at local shipyards, machine shops and boiler shops, one month at sea in the engine room of different type boats, and one month subsequent training and examination at Stevens. It is expected to have about one hundred men in each of these divisions, or five hundred in all.

Three of the divisions will be quartered in barracks now in the course of construction on the college grounds at the corner of Sixth and Hudson Sts., adjoining the Carnegie Laboratory of Engineering. The school divisions will attend classes in the lecture rooms of the college and will take their meals at the college mess hall at Castle Stevens.

The instructors for the school, with the exception of the civilian director, will be regularly appointed commissioned officers of the United States Naval Auxiliary Reserve, selected particularly for their especial work.

Quotas are furnished for this school by the various Naval Districts throughout the country as outlined by the Navy Department and are required to meet the following qualifications: (a) Men of ability and officer material; (b) age 21 to 30, inclusive; (c) completed high-school course and graduate of engineering course at a recognized technical school or an equivalent of the above; (d) must be regular Navy, N. N. V., or N. R. F. (any class) for general service; (e) physically qualified for line officer—standard of regular Navy.

Men may be newly enrolled specifically for this course by applying to their Naval District enrolling officer and then be transferred by the commandant of that district to the school in his weekly quota.

That the students will be required to perform hard work is evidenced by the routine of duty which has been posted as follows: 6, reveille; 6:15, assembly; 7, breakfast formation; 7:15, breakfast; 8:15, study call; 9:45, retreat; 10, study call; 11:30, retreat; 12:15, dinner formation; 12:30, dinner; 1:15, study call; 2:45, retreat; 3, study call; 4:15, retreat; 4:30, drill; 5:30, retreat; 6, supper formation; 6:15, supper; 7, study call; 9:30, retreat; 10, taps.

It was expected that the first course would start on Mar. 25 and the second course about Apr. 22. After the barracks are completed, a unit of 25 men will be enrolled each week, and after the school is in full operation about one hundred engineer officers will be graduated each month. The rank of the successful students will be that of ensign; the unsuccessful students will be given appropriate ratings by the Supervisor, Naval Auxiliary Reserve and transferred to Pelham Park for general detail.

Turbine Propelling Units Wanted

Quotations are requested by the Emergency Fleet Corporation, Washington, D. C., on one hundred turbine propelling units, to be constructed in accordance with the following general specifications: (1) Capacity, 3000 s.hp.; (2) propeller speed, 90 r.p.m.; (3) steam pressure, 210 lb.; (4) superheat, 50 deg. F.; (5) vacuum, 28 in.; (6) each propelling unit is to consist of a high-pressure turbine and a low-pressure turbine with backing turbines, and a double herringbone reduction gear and housing, and is to be complete with all necessary attachments including a forced-oil lubricating system, cross-connecting piping, overspeed emergency valve and other necessary appurtenances. The propelling unit shall meet the requirements of Lloyd's and of the American Bureau of Shipping.

Segregated prices are to be stated for complete sets of spare parts. No auxiliary equipment, such as condensers and circulating pumps, is to be provided with the main propelling unit.

The time of delivery is of prime importance. Bidders are to state in proposal the earliest possible delivery of complete units and are to tabulate a complete schedule of deliveries which are to be guaranteed.

Proposals are to be complete in every respect and are to be accompanied by a full set of specifications and general and detail drawings showing the equipment contemplated.

Bidders are to state the type of turbine proposed; the turbine speed; the steam consumption at ¼, ½, ¾, full load and 1¼-load (in pounds of steam per s.hp.-hr.); gear efficiency; the length, width, height and weight of the propelling unit; the sizes of the steam and exhaust pipes; and a list of all gages, valves, strainers, case-hardened wrenches, wrench-boards, packing, lifting bolt, and similar devices supplied with the unit. The name of manufacturer and the point of manufacture and delivery are to be stated.

It is contemplated that manufacturers will bid on their standard turbine propelling equipment complete in every respect. Proposals must be submitted within ten days after date hereof. No bidding bond is required.

Alternative proposals are expressly desired on equipment conforming generally to the specifications of this inquiry. Alternatives will be received upon turbines operating at a shaft speed of 100 r.p.m.

Washington, D. C., Mar. 23, 1918.

New Publications

THE PETROLEUM AND NATURAL GAS REGISTER 1917-1918. Published by The Oil Trade Journal, New York. Size 9 x 11½ in.; 548 pages. Price, $12.

This is a representative catalog of the trade and is a collection of much valuable information about the petroleum and natural-gas industries of the United States, Canada and Mexico, giving names of officers, capital stock, location of properties and other valuable data, together with financial statements that fit in with facts as to organizations and operations. The text is divided into lists of refiners of petroleum; manufacturers and compounders of lubricating oils, greases, petroleum, etc., and gives marketers and jobbers grouped under Eastern, Central and Southern, and Western States; producers of petroleum, Eastern and Central States, Oklahoma and Kansas, Texas and Louisiana, and Western States; also lists of oil pipeline companies, casinghead-gasoline manufacturers, natural-gas producers and distributers, manufacturers of and dealers in supplies and equipment for the oil and natural-gas industries, and a directory of officers and members of the oil and gas associations and clubs in the United States. The arrangement and classifications of data are well planned for enabling the reader to obtain the desired information with little difficulty.

Personals

Joseph Harrington, of Chicago, the well-known combustion engineer, has been elected vice president and advisory engineer of the Chicago Superheater Co. E. A. Geoghegan has resigned.

A. F. Ausman, formerly vice president of McMaster-Carr Supply Co., of Chicago, is now Chicago district manager of Nagle Corliss Engine Works, of Erie, Penn., with offices in the Monadnock Block.

Frederick L. Ray, past president of the National Association of Stationary Engineers, has resigned as chief engineer of the Merchants Heat and Light Co., of Indianapolis, Ind., to take a corresponding position with the Erie Lighting Co., Erie, Penn.

A. D. Alexander has purchased the Pittsburgh (Penn.) office of the Richard D. Kimball Co., consulting engineers, and will continue the business under his own name. Mr. Alexander has been resident engineer in charge of the Kimball office for the last three years and was formerly engineer with the Pittsburgh Board of Public Education.

C. H. Van Hooven, claim agent of the Manila, (P. I.) Electric Railroad and Light Co. who has been visiting the United States for the purpose of consulting with officers of the J. C. White Management Corporation, New York, the operating managers of the Manila Co. is returning to the Philippines by way of Hawaii and Japan. While in the United States, Mr. Van Hooven also devoted considerable time to inspecting the claim methods of electric railways in a number of large cities. He has been connected with the Manila Electric Railroad and Light Co. for the last ten years. He was recently admitted to the Philippine bar, having successfully completed the law course at the Manila University.

Miscellaneous News

The Wentworth Institute, Boston, Mass., held its seventh public exhibition of work done in the various departments on Mar. 21. It appealed especially to persons interested in modern methods of training young men for skilled occupations in the trades and industries. A short, intensive 12-weeks' full-time day course in military engineering will be given at the Institute, in coöperation with First Corps Cadet Veteran Association, April 8 to July 1.

Steam Power Plants Close to Save Oil—All but one of the steam plants of the three big electric power companies operating in San Francisco closed down on the night of Mar. 19 and will remain closed for the remainder of the season if possible. The Pacific Gas and Electric Co., Great Western Power Co. and the Sierra & San Francisco Power Co., have inter-connected their heavy power lines and plants and the one operating steam plant will act as a standby in case of accident to the transmission lines from the hydro-electric plants of the three companies. The shutting down of the steam plants is in line with the program adopted for the conservation of fuel oil. The Potrero plant of the Pacific Gas and Electric Co. will act as the standby at night and the steam plants of the other two companies will alternate as standbys during the day, each plant taking an eight-hour shift.

Business Items

The H. W. Johns-Manville Co. has opened a branch office at 1015 A Street, Tacoma, Wash.

The Duquesne Electric and Manufacturing Co., of Pittsburgh, Penn., announces the opening of a branch office at 230 South La Salle St., Chicago.

The Vulcan Soot Cleaner Sales Co. has transferred its general sales office from 230 So. La Salle St., Chicago, to Du Bois, Penn., in order to bring the sales, factory and engineers in immediate touch. G. L. Simonds is in charge.

The American Thread Co.'s general engineering department will be transferred from the Merrick Mills at Holyoke, Mass., to the company's head office at 260 West Broadway, New York City, on Apr. 1. Malcolm Curry, general engineer, Kenneth B. Millett, assistant general engineer, and A. C. Richardson will be located at this latter office.

The Jos. W. Hays Corporation, of Michigan City, Ind., has purchased the business and good will of the Combustion Appliance Co., of Chicago, manufacturers of the Hays line of combustion testing apparatus. The general offices will be maintained at Michigan City. Following are the authorized representatives of the company: For New England States, Eagle Oil and Supply Co., 45 India St., Boston, Mass.; New York City and vicinity, Stephen H. Payne, 30 Church St., New York; Pennsylvania, New Jersey, Delaware, Maryland, Virginia and West Virginia, the Paul B. Huyette Co., 5 So. 18th St., Philadelphia, Penn.; Ohio, the Hays Engineering Co., 614 Commerce Bldg., Columbus, Ohio; Indiana, Acme Engineering Agency, 423 Fletcher-American Bank Bulding, Indianapolis, Ind.; Illinois and Wisconsin, The Hays Instrument Co., 1426 Consumers Bldg., Chicago, Ill.; Minnesota, Montana, North and South Dakota, The R. B. Whitacre Co., 205 S. Robert St., St. Paul, Minn.; Oklahoma and Texas, The Chas. W. Hays Co., Tulsa, Okla.; Louisiana and Mississippi, Henry J. Malochee, 917 Hennen Bldg., New Orleans, La.; The Pacific Coast, The Braun-Knecht-Heimann Co., 576-584 Mission St., San Francisco, Cal., and The Braun Corp., 363-371 New High St., Los Angeles, Cal. Agency arrangements will be considered with aggressive and responsible people in unoccupied territory. E. A. Acers is president and general manager of the Jos. W. Hays Corporation.

NEW CONSTRUCTION

Proposed Work

Vt., Brattleboro—The Twin States Gas and Electric Co. has been granted permission by the Public Service Commission to build transmission lines in Brattleboro, Bennington and St. Johnsbury, and to improve its power plant at West Dummerstown. W. H. Richardson, local mgr.

Mass., Adams—The Renfrew Manufacturing Co. plans to build a power plant on Columbia St.

Mass., Fall River—The stockholders of the Fall River Electric Co. will petition the Gas and Electric Light Commissioners for authority to increase its capital stock from $1,400,000 to $2,100,000; proceeds to be used for paying its outstanding indebtedness, also for new high tension transmission system to be built over the Taunton River. A. H. Kimball, 85 North Main St., Gen. Mgr.

Mass., Millbury—The New England Power Co., 18 Grafton St., Worcester, is having surveys made for the construction of a high tension transmission line from here to Webster. S. C. Moore, Gen. Mgr.

Mass., Worcester—The W. H. Sawyer Lumber Co., 26 Lincoln St., is having plans prepared for the construction of a power house in connection with its new plant. Estimated cost, $70,000.

N. Y., Buffalo—The J. H. Williams Co., 400 Vulcan St., plans to increase the capacity of its power plant during the year.

N. Y., Lockport—The Lockport Light, Heat and Power Co., controlled by the United Gas and Electric Co., 61 Broadway, New York, has been authorized by the Public Service Commission to issue $106,700 capital stock; proceeds to be used for paying the outstanding indebtedness. J. A. Perkins, Gen. Mgr.

N. Y., New York—The Interborough Rapid Transit Co. has filed plans for the construction of a 3-story, 40x41 ft. transformer station on 74th St. east of Ave A. Estimated cost, $12,900. G. H. Pegram, Ch. Engr.

N. Y., Rochester—The Rochester Railway, Light and Power Co. has been granted permission by the Public Service Commission to issue $2,000,000 capital stock to cover the cost of the recent improvements in the equipment of its Genesee River hydraulic plant. T. H. Yawger, 34 Clinton Ave., Supt.

N. Y., Sandlake—The McLaren Knitting Co. has applied to the Town Board for a franchise to construct an electric transmission line to enable it to secure electricity to operate its mills here.

Penn., Chester—The Delaware County Electric Co., Lansdowne, controlled by the Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, is building a large steam power station on the Delaware River here. A. R. Granger, Mgr.

Penn., Philadelphia—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, here, under Schedule No. 1725, plain enameled magnet wire; Schedule No. 1726, 300 counter scales; Schedule No. 1727, standard steel bolts.

Del., Bowers—W. E. Kelly is interested in a project to organize a company to install and operate an electric light plant here.

Md., Ellicott City—The Town Commissioners plan to issue bonds for the construction of an electric-light plant.

Md., Pylesville—The Fawn Grove Light and Power Co., Fawn Grove, Pa., will construct a new concrete dam at their Eden Mills plant on lower Deer Creek near Pylesville, about 300 ft. long to carry 30 ft. of which only 16 ft. will be built this season. The company will install water wheels and one 125 kva. generator, 3 phase, 60 cycle, 2200 volts with exciter, switchboard, etc., and require from four to seven miles of No. 6 copper transmission wire. Work will be done by day labor. William Russell Smith Co., York, Pa., Engr.

N. C., Southport—J. G. White & Co., 43 Exchange Pl., New York, has purchased property of Southport Electric Light and Power Co. The new owners plan to spend about $20,000 for improving same.

S. C., Charleston—Charleston Consolidated Railway and Lighting Co. plan to increase the capacity of its power house on Meeting St. P. H. Gadsden, Pres.

Ga., Jackson—City plans to improve the electric-light plant to include rebuilding 1½ mi. of pole line and installation of high pressure centrifugal pump, 2 stage, electrically driven. W. E. Merck, Gen. Mgr.

Ala., Ensley—The Tennessee Coal, Iron and Railway Co. will install a 7500 k.w. generator in power station No. 1 at the Ensley blast furnaces.

Ala., Mobile—The Chickasaw Shipbuilding Co. is constructing a power plant at its yards, here. Estimated cost $750,000. The plant will have two 4000 k.w. turbo generator units and three air compressors of 8800 cu.ft. per minute will be installed. Equipment has been purchased.

La., Oak Grove—City plans to install an electric lighting plant soon. Address L. Grathwell, Oak Grove.

Ky., Graham—The W. G. Duncan Co., Greenville, plans to construct a 75x100 ft. power house, also build from 4 to 5 mi. transmission line to connect Greenville, Luzerne and Depoy. Material and equipment purchased.

Ky., Hazard—The Perry Coal and Lumber Co. plans to install an electrically operated plant for a coal development on Louisville & Nashville Railroad in Perry County.

Ky., Indian Bottom—The Middle West Coal Co. will receive bids until Mar. 30, for the erection of a power plant midway between here and Jeremiah. Estimated cost, $50,000.

Ind., Attica—The city plans to rebuild its electric-light and water-works plants which were recently destroyed by fire with a loss of $60,000. G. McDonald, Mgr.

Ind., Gary—The Gary Street Railway plans to construct a new power station on 11th Ave.

Ind., Indianapolis—Bids will be received by the Board of Trustees of Indiana University, Bloomington, for the construction of a 1-story, 88x91 ft., brick and reinforced concrete power house in connection with the new medical building to be built on West Michigan St. Bids will be received at the same time for furnishing the electric equipment, boilers and heating equipment, refrigerating and ice-making equipment, hot water equipment, heating and ventilating apparatus, electric wiring, etc., for both buildings. R. F. Daggett, 956 Lemcke Annex, Arch.

Ill., Biggsville—The Biggsville Light Co. plans to change its system to alternating current, single phase, and extending its service to two small towns and farms along the line. A 75 kva. single phase, 2200 or 1199 volt machine will be required D. W Lee, Vice-Pres.

Ill., Charleston—Council authorized $20,000 bond issue, proceeds of which will be used for improving electric-light plant and water-works system.

Ill., Mt. Olive—City will hold an election Apr. 16 to vote on $8000 bonds to be used for the improvement of the electric-light plant. It is also proposed to equip the water-works pumping station with electrically operated machinery. W. S. Merkle, Federal Reserve Bank Bldg., St Louis, Mo., Engr

Ill., Rockford—City will hold election in April to vote on $500,000 bonds to install an electric-light plant.

Iowa, Boyden—Veenschoten Bros., Boyden, have been granted a franchise by the Board of State Railroad Commissioners to construct and operate electric transmission lines on certain highways and roads in Sioux County for a period of 25 years

Iowa, Dubuque—The Chicago, Milwaukee and St. Paul Railway plans to improve the power plant at its shops here. Estimated cost, $50,000. C. F. Loweth, Chicago, Ill., Ch. Engr

Iowa, Lanesboro—City will hold election March 8 to vote on $7000 bonds, proceeds will be used for building electric-light plant.

Ia., Ossian—Harry Bullard, owner of the local electric light and power plant, has sold same to A. G. O'Rear of Mason City The new owner plans to improve the same

Minn., Ionn—City plans to install electric-light and power plant to cost approximately $10,000.

Kan., Chapman—The United Telephone Co. is building a new transformer station here. Plans are also being considered by the company for other improvements.

Kan., Lawrence—The Bowerstock Mills and Power Co., Lawrence, plans to build a large boiler house soon. R. C. Jackman, Mgr.

Kan., Oakley—Plans are being considered by the city for the construction of a transmission line from here to Colby to secure electricity to operate the local system.

Kan., Ottawa—City plans to build a transmission line on South Willow St., from 11th to 15th St., thence on 15th St. from Willow to Locust Sts. W. O Myres, Supt.

S. D., Miller—The City Council contemplates calling an election to vote on $30,000 bonds to install an electric-light and power plant.

Ark., Helena—The Helena Gas and Electric Co. plans to enlarge its plant and install new machinery.

Tex., Bryan—City will purchase additional transformers for its electric-light and power system.

Tex., San Angelo—Plans are being considered by the Interstate Corporation, 141 Broadway, New York, for extending its electric transmission system now running from San Angelo to Ballinger to Coleman and Brownwood. E. Burrow, San Angelo, Ch. Engr.

Okla., Hominy—The Hominy Ice, Light and Power Co. has purchased an additional electric generating unit consisting of a 150 h.p. gas engine directly connected to a 100 k.w., 3 phase, 60 cycle, 2300 volt generator for its plant here

Okla., Laverne—City will spend $13,000 to construct an electric-light plant. Address The Mayor. Noted Dec. 18.

Okla., Miami—City will expend about $45,000 to improve and extend its electric-light plant. Address The Mayor. Noted Nov 6

Okla., Shattuck—City plans to spend between $20,000 and $30,000 to build electric-light plant to develop 150 to 300 h.p. A. C. Oliver, Mayor. Burns & McDonnell, Interstate Bldg., Kansas City, Mo., Engr

Colo., Colorado Springs—The Golden Cycle Co. has under consideration the construction of an electric lighting plant.

N. M., Des Moines—Village Trustees will call an election to vote on $50,000 bonds to purchase the local electric-light plant and water-works system and improve and extend same.

Ariz., Yuma—The City plans to improve and enlarge the electric-lignt and power plants and the water-works system. Among improvements contemplated is the erection of an electric transmission line of 6600 volts to supply nearby ranches. Fred Kuecke, Supt.

Wash., Tacoma—City will hold an election soon to vote to purchase either a completed power plant at a cost of approximately $5,000,000 or a site on which a plant may be built. L. Evans, Gen. Supt. Noted Feb. 8.

Wash., Tacoma—City is having plans prepared by its Electrical Department for the erection of a substation L Evans, Gen. Supt

Wash., Tacoma—Light and Water Department plans to replace conduits underground from Nisqually sub-station at 23rd and C Sts., to Winthrop Ave. New circuits will be for shipyards and tide flats L Evans, Gen. Supt.

Calif., Hanlon—The Imperial Irrigation District, Masonic Temple Bldg., El Centro, plans to construct a new power line from here to point on the Alamo Estimated cost $11,000.

Calif., Los Angeles—The Public Service Commission authorized the leasing from the Harbor Commission of a tract of land on the east side of the Harbor Blvd. to be used as a site for a sub-station for the municipal power system. The site adjoins the property of the Los Angeles Dry Dock and Shipbuilding Co. A Scattergood, Ch. Electrical Engr.

Calif., Los Angeles—The Riverside-Southern Sierras Power Co., 611-12 Lymes Bldg., Denver, Colo., plans to expend about $279,000 for reconstructing one of its main transmission lines, extending for distance of 60 mi. from hydro-electric plant located on Rush Creek. V. Presto, Riverside, Gen. Mgr.

N. B., Woodstock—The Woodstock Electric Railway Light and Power Co. plans to improve its plant here this summer. Improvements contemplated include installation of Hercules turbine, type D of Holyoke Manufacturing Co. developing 137½ h.p. at 13 ft. head, belt connected to a Westinghouse generator in synchronism with two generators. C. D Johnson, Mgr

Ont., London—The Helena Costume Co., 190 King St., is in the market for a 60 k.w., 110 volts, 680 r.p.m., compound wound, direct current generator.

CONTRACTS AWARDED

Mass., New Bedford—The Union Street Railway has awarded the contract for the construction of the superstructure of a 2-story, 98x126 ft., brick and steel building to be used as a boiler house and turbine room, to J. W. Bishop Co., 109 Foster St., Worcester. Estimated cost, $135,000.

N. J., West Orange—T. A. Edison, Inc., Lakeside Ave., has awarded the contract for the construction of a 1-story, 100x100 ft. reinforced concrete power plant, to the Underpinning and Foundation Co., 270 Broadway, New York City. Noted Oct. 23.

Penn., Nanticoke—The Board of Managers of the State Hospital, has awarded the contract for a 1-story, 50x65 ft. power house, to John Curtis & Co., 1 Hickory St., Wilkes-Barre.

Penn., Reynolds—The Atlas Powder Co. has awarded the contract for the construction of a power plant here, to A. Breslin, Summit Hill.

O., Salem—The Salem Lighting Co. has awarded the contract for a 1-story, 31x40 ft. boiler house addition, to Walker & Curley Co., East End Trust Bldg., Pittsburgh, Pa. Estimated cost, $30,000.

Ind., Robey—The Western Products Co., Robey, has awarded the contract for the construction of a 1-story power house, to the Industrial Building Co., 38 South Dearborn St., Chicago, Ill. Estimated cost, $5600.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1] Mar. 28, 1918	Individual[1] Mar. 28, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	1.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $1, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1] Mar 28, 1918	Individual[1] Mar. 28, 1918
Pea	$5.05	$5.80
Buckwheat	4.30—5.00	5.50—5.80
Barley	3.25—3.50	4.00—4.25
Rice	3.75—3.95	4.50—4.80
Boiler	3.50—3.75	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Mar. 28, 1918	One Yr. Ago	Mar 28, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties Mar 28, 1918	Mt. Olive & Staunton Mar. 28 1918	Standard Mar. 28, 1918
6-in. lump	$2.65-2.80	$2.65-2.80	$2.65-2.80
2-in.-lump	2.65-2.80	2.65-2.80	2.65-2.80
Steam egg	2.65-2.80	2.65-2.80	2.65-2.80
Mine-run	2.40-2.55	2.40-2.55	2.40-2.55
No. 1 nut	2.65-2.80	2.65-2.80	2.65-2.80
2-in. screen	2.15-2.30	2.15-2.30	2.50-2.65
No. 5 washed	2.15-2.30	2.15-2.30	2.50-2.65

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

Prices—Materials and Supplies

These are prices to the power plant by jobbers in the larger buying centers east of the Mississippi. Elsewhere the prices will be modified by increased freight charges and by local conditions.

ELECTRICAL SUPPLIES

KNIFE SWITCHES—Following are net prices each in cities named for knife switches mounted on slate base, front connected, punched clip type, 250 volts:

	30 Amp.	60 Amp.	100 Amp.	200 Amp
D. P. S. T. fuseless	$0.52	$0.93	$1.90	$3.42

Steam—Discounts from list

First grade... 30%   Second grade... 30-5%   Third grade... 40-10%

RUBBER BELTING—The following discounts from list apply to transmission rubber and duck belting:

Competition	50%	Best grade	20%
Standard	35%		

LEATHER BELTING—Present discounts from list in the following cities are as follows:

	Medium Grade	Heavy Grade
New York	40%	35%
St. Louis	45%	40%
Chicago	30+10%	40+5%
Birmingham	35%	35%
Denver	35%	30%

RAWHIDE LACING—40%.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.90
Asbestos for high-pressure steam	1.60
Duck and rubber for piston packing	1.00
Flax, regular	.90
Flax, waterproofed	1.10
Compressed abestos sheet	1.00
Wire insertion asbestos sheet	1.20
Rubber sheet	.60
Rubber sheet, wire insertion	.90
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided and graphited, for valve stems and stuffing boxes	1.10
Asbestos wick, ½- and 1-lb. balls	.70

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING		BLOCKS AND SHEETS	
Pipe Size	Standard List Per Lin.Ft.	Thickness	Price per Sq.Ft.
1-in.	$0.27	½-in	$0.27
2-in.	.36	1 -in	.30
6-in.	.80	1½-in.	.45
4-in.	.60	2 -in.	.60
3-in.	.45	2½-in.	.75
8-in.	1.10	3 -in	.90
10-in.	1.30	3½-in.	1.05

85% magnesia high pressure		5% off
For low-pressure heating and return lines	4-ply	58% off
	3-ply	60% off
	2-ply	62% off

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots:

	Cincinnati	Chicago	St. Louis	Birmingham	Denver
Cup	7	5¼	6.1	7½	10
Fiber or sponge	8	6	6.4	15	15
Transmission	7	6	6.4	10	15
Axle	4½	4	3.3	..	5
Gear	4½	4½	6.5	7½	6
Car journal	22 (gal.)	3½	4.6	5	6

COTTON WASTE—The following prices are in cents per pound:

	New York		Cleveland	Chicago
	Mar. 28, 1918	One Year Ago		
Colored mixed..	8.50 to 12.00	10.00 to 12.00	12.50	12.00 to 12.50
White	11.00 to 13.00	13.00 to 15.00	16.00	10.00 to 11.00

WIPING CLOTHS—In Cleveland the jobbers' price per 1000 is as follows:

13¼ x 13½ .... $45.00   13¼ x 20½ $52.00

In Chicago they sell at $30@33 per 1000.

LINSEED OIL—These prices are per gallon:

	New York		Cleveland		Chicago	
	Mar. 28, 1918	One Year Ago	Mar. 28, 1918	One Year Ago	Mar. 28, 1918	One Year Ago
Raw per barrel	$1.56*	$0.99	$1.60	$1.05	$1.65	$0.98
5-gal. cans	1.66*	1.09	1.75	1.15	1.75	1.08

* Nominal.

WHITE AND RED LEAD in 500-lb. lots sell as follows in cents per pound:

	Red				White	
	Mar. 28, 1918		1 Year Ago		Mar. 28, 1918	1 Yr. Ago
	Dry	In Oil	Dry	In Oil	Dry and In Oil	Dry and In Oil
25- and 50-lb. kegs	11.50	11.00	10.50	11.00	10.50	10.50
12½-lb. keg	11.75	11.25	10.75	11.25	10.75	10.75
100-lb. keg	11.25	11.50	11.00	11.50	11.00	11.00
1- to 5-lb. cans	13.25	13.00	12.50	12.50	13.00	12.50

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel 7⁄16 and smaller	30%	35%	40%*
Tinned	30%	35%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York ..... $6.09½   Cleveland ..... $5.85   Chicago $5.50

Coneheads, same sizes:

New York ..... $6.19½   Cleveland ..... $5.95   Chicago $5.60

FIRE BRICK—Quotations on the different kinds in the cities named are as follows, f.o.b. works:

	New York	Chicago
Silica brick, per 1000	$50.00 to 55.00	$50.00
Fire clay brick, per 1000, No. 1	45.00 to 55.00	....
Magnesite brick, per net ton	135.00 to 145.00	....
Chrome brick, per net ton	135.00	....
Deadburned magnesite brick, per net ton	85.00 to 90.00	....
Special furnace chrome brick, per net ton	60.00 to 70.00	60.00 to 80.00

Standard size fire brick, 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade, $55 to $65; St. Louis grade, $40 to $50.
Birmingham—Fire clay, $25 to $30.
Chicago—Second quality, $25 per ton.
Denver—Silica, $35 per 1000.

FUEL OIL—Price variable, depending upon stock. New York quotations not available owing to this fact. In Chicago and St. Louis the following prices are quoted:

	Chicago	St. Louis
Domestic light, 22-26 Baumé	5c.	None
Mexican heavy, 12-14 Baumé	7c.	7⅒c.

Note—There is practically no fuel oil in Chicago at present time.

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Mar. 28, 1918	One Year Ago
New York	$15.00	$8.00
Cleveland	15.30	7.50
Chicago	15.00	6.00

In coils an advance of 50c. usually is charged.
Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St. Louis	Denver
6 in. by 30 ft	$5.59	$4.94	$4.94	$4.32
7 in. by 30 ft	7.40	6.60	6.60	5.80
7 in. by 35 ft	10.70	9.60	9.60	8.55
8 in. by 35 ft	12.20	10.90	10.90	9.65
7 in. by 40 ft	12.35	11.00	11.00	9.75
8 in. by 40 ft	13.75	12.15	12.15	10.65
8 in. by 45 ft	18.20	16.20	16.20	14.30
8 in. by 50 ft	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads.

For plain pine poles, delivered New York, the price is as follows:

10-in. butts, 5-in. tops, length 20-30 ft	$6.00
12-in. butts, 6-in. tops, length 30-40 ft	8.50
12-in. butts, 6-in. tops, length 41-50 ft	9.50
14-in. butts, 6-in. tops, length 51-60 ft	17.00
14-in. butts, 6-in. tops, length 61-71 ft	18.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh, basing card in effect July 2, 1917, for iron, and May 1 for steel:

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized
BUTT WELD					
¾ to 3	49%	35½%	¾ to 1½	33%	17%
LAP WELD					
2	42%	29½%	2	26%	12%
2½ to 6	45%	32½%	2½ to 4	28%	15%
7 to 12	42%	28½%	4½ to 6	28%	15%
13 and 14	32½%	....	7 to 8	20%	8%
15	30%	....			
BUTT WELD. EXTRA STRONG PLAIN ENDS					
¾ to 1½	47%	34½%	¾ to 1½	33%	18%
2 to 3	48%	35½%			
LAP WELD. EXTRA STRONG PLAIN ENDS					
2	40%	28½%	2	27%	14%
2¼ to 4	43%	31½%	9 to 12	15%	3%
4½ to 6	42%	30½%	7 to 12	25%	12%
7 to 8	38%	24½%	2½ to 4	29%	17%
9 to 12	33%	19½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts hold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	38%	42%	34.27%
3½ to 6 in. lap welded	18%	38%	21.27%
7 to 12 in. lap welded	10%	35%	21.27%

	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	22%	22%	19.27%
3½ to 6 in. lap welded	List	18%	13.27%
7 to 12 in. lap welded	List+20%	20%	6.27%

Malleable fittings, Class B and C, from New York stock sell at 5 and 5% from list prices. Cast iron, standard sizes, 34 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13, as agreed upon by manufacturers and the Government:

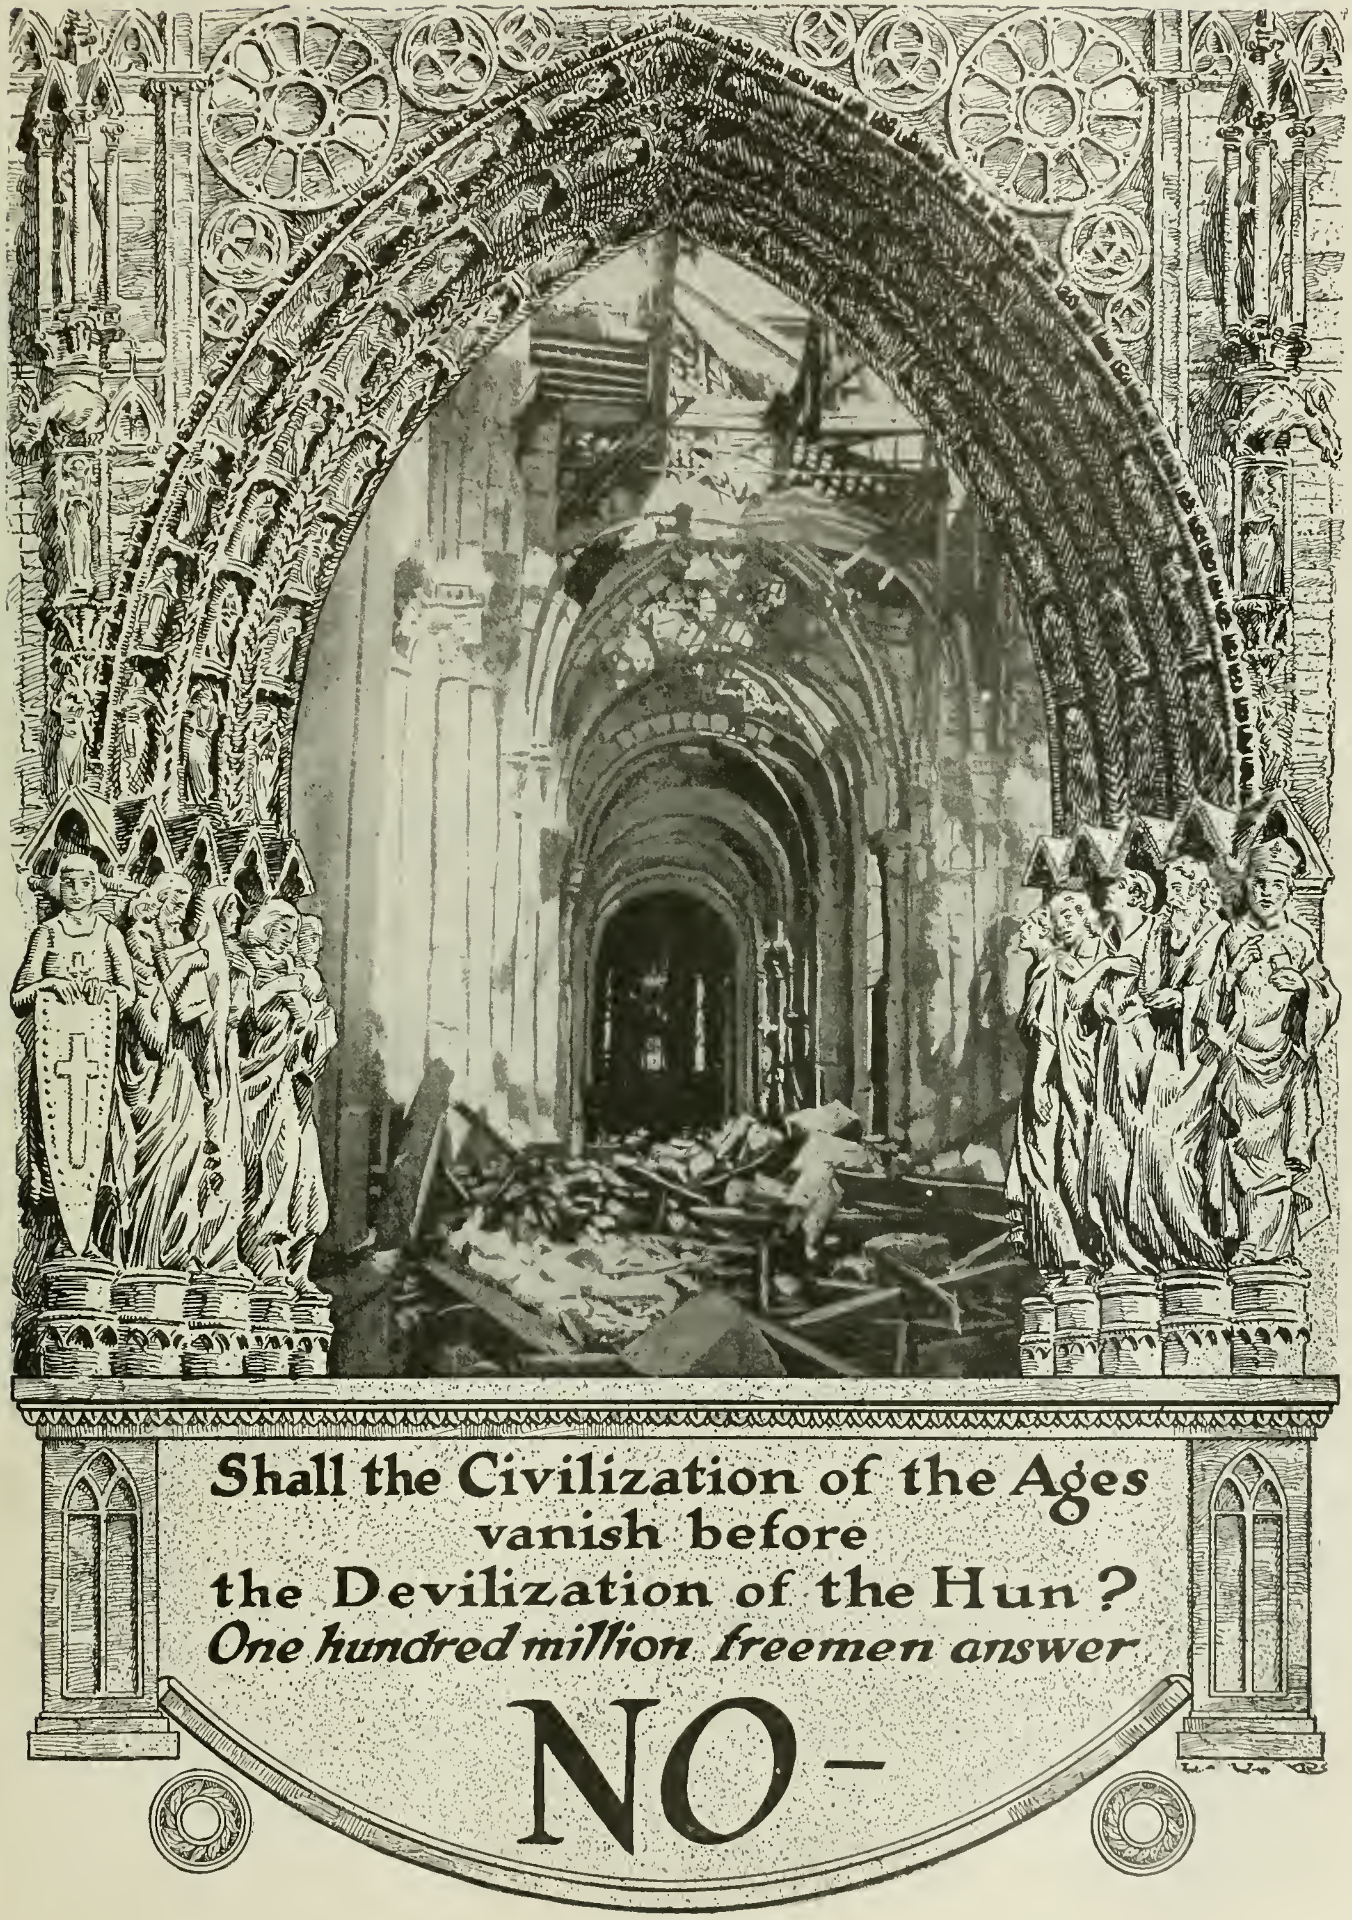
Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+5
2¼ in.	17½	2½ to 2¾ in.	+7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

	Per Net Ton		Per Net Ton
1 in.	$310	1¾ in.	$220
1¼ in.	280	2 to 2¼ in.	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

Vol. 47, No. 15 POWER April 9, 1918



Reconnecting Induction Motors—For Changes in Number of Poles

By A. M. DUDLEY

Designing Engineer, Westinghouse Electric and Manufacturing Co.

The effect upon the operation of the machine caused by changing the number of poles in an induction-motor winding is discussed. Tables are given in which data are compiled for a 54-coil winding having a coil spread of 1 to 7, reconnected for 4, 6, 8, 10 and 12 poles. These data are discussed in a way that will make them easily applied to any induction-motor winding.

THE speed of an induction motor expressed in revolutions per minute = (cycles × 120) ÷ number of poles. The speed so determined is called synchronous speed and is very nearly the same as the no-load speed. When operating under full load the speed will be a few revolutions less than this—for ordinary motors, on an average of about 95 to 97 per cent. of the synchronous speed. The synchronous speed is the speed at which the rotating magnetic field is traveling around in the stator, and the difference between this and the full-load speed of the rotor (3 to 5 per cent.) is called the "slip" of the motor.

From the equation for revolutions per minute it can be seen at once that if the speed of the motor is to be changed, it is necessary to change either the cycles or the number of poles. Or, assuming that the cycles have been changed and that it is necessary to keep the same speed as before, it will be necessary to change the number of poles. So far as the cross-connections themselves are concerned, and admitting windings where all the pole-phase groups do not have the same number of coils, as discussed in the article in the May 22, 1917, issue of *Power*, it is evident that any winding might be connected for several different numbers of poles and for either two-phase or three-phase, by the simple expedient of changing the number of coils in each pole-phase group.

For example, a winding having 54 slots and 54 coils if arranged for three-phase 6 poles would have 3 coils per group and 18 pole-phase groups. If the same winding is rearranged for three-phase 4 poles there will be 12 pole-phase groups having alternately 4 and 5 coils per group. Or, if the same winding is arranged for two-phase 4 poles there will be 8 pole-phase groups, 6 of which would have 7 coils and 2 of which would have 6 coils, or 54 total. There are practical limits beyond which this form of reconnection cannot properly be carried and which are discussed farther on in this article, but before proceeding to a discussion of them attention is called to some typical cases of reconnection of this nature.

Fig. 1 shows a 54-slot winding having a coil pitch of 1 and 7 as arranged for 6 poles and connected series star. There are 3 coils in every group. Fig. 2 shows the same winding as Fig. 1 except grouped and connected for 4 poles. It will be noted that there are now 3 × 4 = 12 pole-phase groups containing alternately 4 and 5 coils per group. Fig. 3 shows the same winding as in Fig. 1 arranged and connected for 8 poles; there are 18 pole-phase groups with 2 coils and 6 with 3, making a total of 24 groups and 54 coils. Fig. 4 is the same winding as Fig. 1 connected for 10 poles. There are 24 groups having 2 coils each and 6 groups with 1 coil, making a total of 30 pole-phase groups and 54 coils. Fig. 5 shows the winding, Fig. 1, connected for 12 poles. There are 18 groups of 2 coils each and 18 groups of 1 coil each, making a total of 36 groups and 54 coils.

Of course all these connections would not normally operate at the same voltage, nor would the horsepower developed be the same, and the speed would vary inversely as the number of poles. Assuming, for example, that the motor was 100-hp. 60-cycle three-phase 440-volts and run at 1160 r.p.m. on the 6-pole connection, the characteristics for the other connections are shown in Table I. Three-phase is assumed throughout.

TABLE I. CHARACTERISTICS OF A THREE-PHASE MOTOR CONNECTED AS IN FIGS. 1 TO 5

Poles	H.P.	Voltage	R.P.M.	Connection
6	100	440	1,160	Fig. 1
4	110	484	1,750	Fig. 2
8	86	375	860	Fig. 3
10	68	300	690	Fig. 4
12	50	220	580	Fig. 5

The only commercial voltages in Table I are the first and last, 440 and 220. To operate the motor on the other connections would require special taps from the transformer, unless some other change could be made in the motor's winding at the same time that the number of poles was changed. For example, the 8-pole connection requires 375 volts. If it so happened that the 6-pole motor was connected in parallel star, then the 8-pole motor could be connected series delta, which would be the same thing as operating the motor on a voltage in the ratio of 1.73 to 2 or $\frac{375 \times 2}{1.73} = 434$, which is approximately the voltage required.

Table I of horsepowers and normal voltages is figured by taking account of the speed and of the chord factor in the following way:

One of the functions of the winding is to be acted upon by the rotating magnetic field and to actually generate a counter-electromotive force which is opposed to and almost equal to the applied line voltage. If, then, in reconnecting for a different number of poles, the assumption is made that the magnetic field in the teeth and air gap remains at a constant value irrespective of the connections, it is at once evident that the generated electromotive force, and consequently the applied line voltage, should vary directly as the speed of the rotating magnetic field, which is practically the same as the revolutions per minute of the motor at no load. For example, in the case cited in the foregoing, if the normal voltage on the 6-pole connection is 440, everything else being equal, the normal voltage on the 12-pole connection should be 220, since the revolutions per

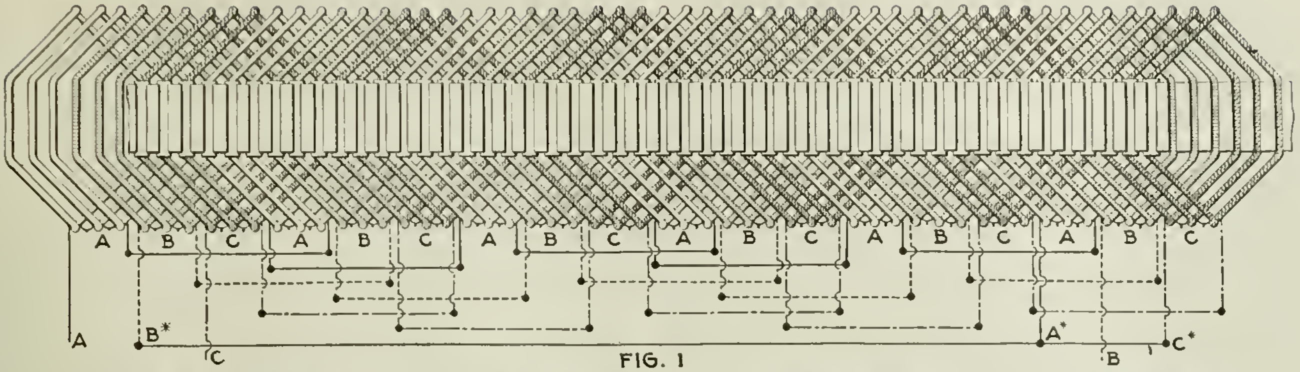


FIG. 1

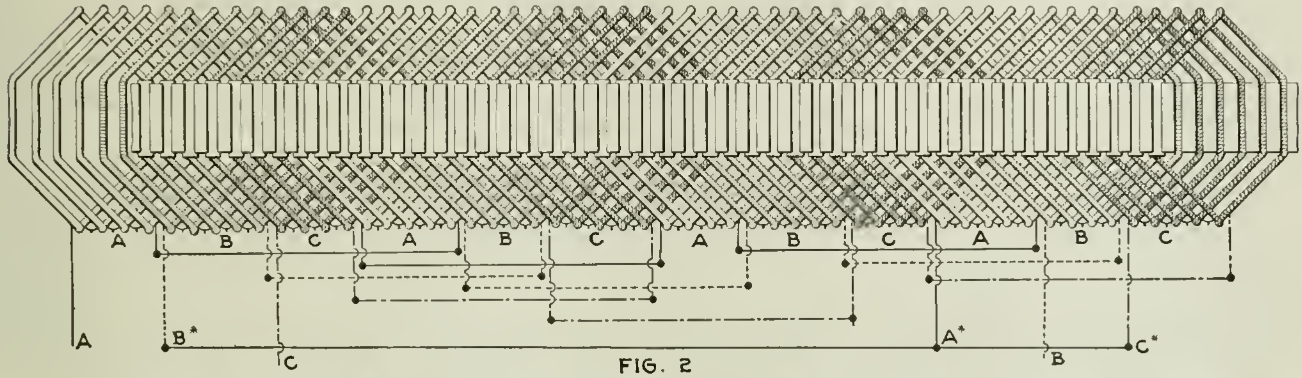

FIG. 2

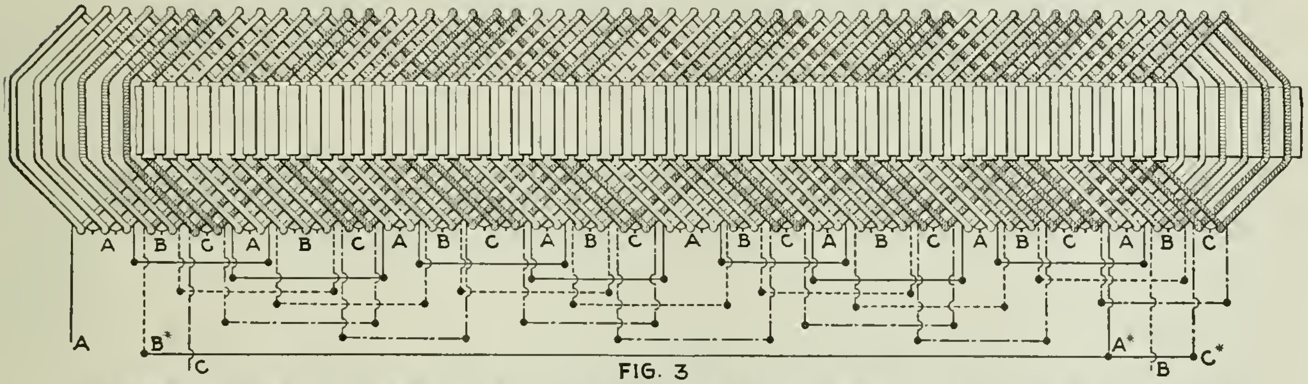

FIG. 3

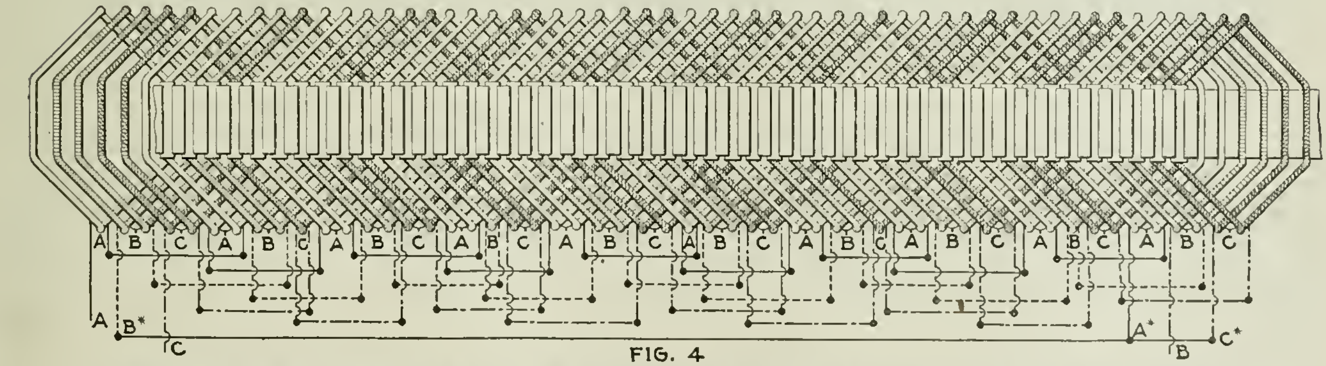

FIG. 4

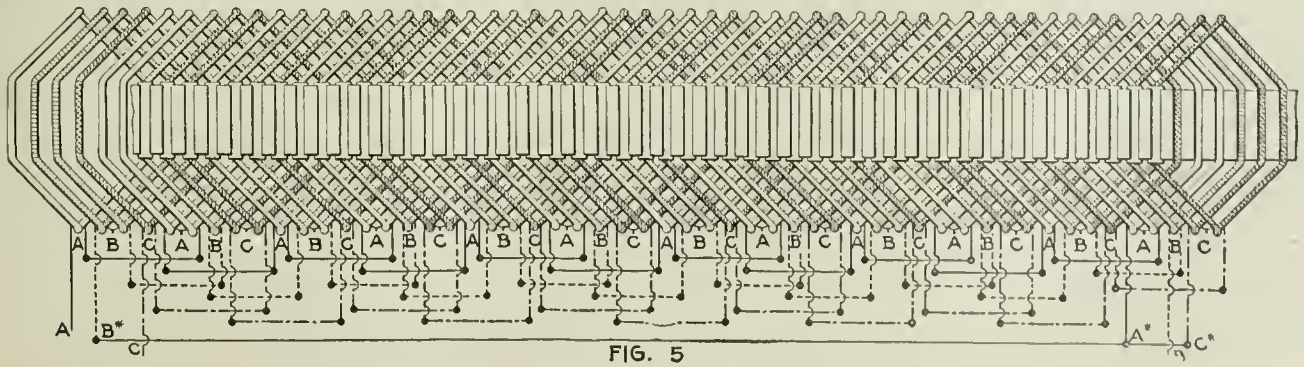

FIG. 5

FIGS. 1 TO 5. INDUCTION-MOTOR WINDING OF 54 COILS GROUPED FOR 4, 6, 8, 10 AND 12 POLES minute of a 12-pole motor are just one-half those of a 6-pole machine.

Practically, the only condition which enters to change the voltage from varying directly as the speed is the "chord factor," which is due to the throw or pitch of the coil. This was described under "Fractional Pitch Windings" in the July 31, 1917, issue. It will be recalled that this is a factor which reduces the voltage generated in a coil because one side of a coil is not exactly under the center of a north pole when the other side is exactly under the center of a south pole. The numerical value of this factor is expressed as the sine of one-half the electrical angle which is spanned by the coil. It may appear in the example given in Figs. 1 to 5 that the chord factor should remain constant since the physical throw of the coils is unchanged. It should be carried in mind, however, that while the coil spread remains unchanged, the number of poles is changed, consequently the pole arc is changed; hence, the relation of the throw of the coil to the pole arc is different in each case. The foregoing can be best shown by Table II, remembering that the throw of the coils is slots 1 and 7 in all cases.

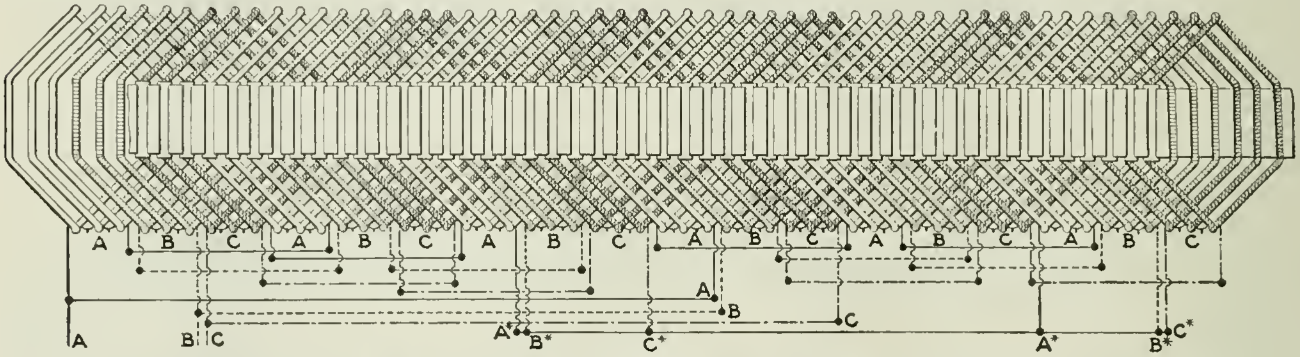

FIG. 6

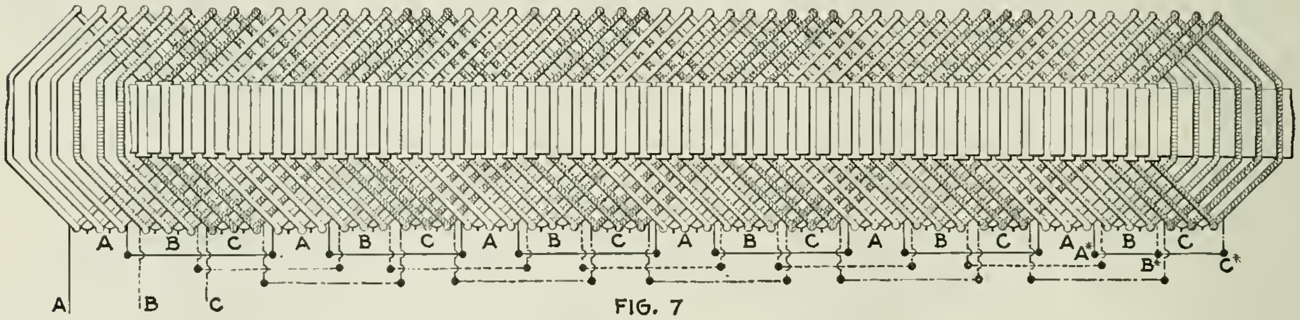

FIG. 7

FIGS. 6 AND 7. INDUCTION-MOTOR WINDING OF 54 COILS GROUPED FOR 6 AND 12 POLES

Fig. 6—Two-parallel-star, connected, 6-pole winding. Fig. 7—Same winding as in Fig. 6 reconnected series-star, consequent pole, for 12 poles.

TABLE II. EFFECTS OF CHANGING THE NUMBER OF POLES IN AN INDUCTION-MOTOR WINDING

Number of poles	4	6	8	10	12
Throw of coil	1–7	1–7	1–7	1–7	1–7
Slots spanned by coil	6	6	6	6	6
Number of slots equivalent to 180 electrical degrees $= \frac{54}{\text{No. of poles}}$	13.5	9	6.75	5.4	4.5
Electrical degrees represented by six slots	80	120	160	200	240
Sine of half the electrical angle covered by the coil throw or pitch = chord factor	0.64	0.866	0.99	0.99	0.866

Table II indicates that the normal 6-pole voltage of 440 must be modified by two factors to find its value for other speeds. These factors and their results are combined in Table III.

On first comparison of Tables II and III it seems peculiar that the 4-pole connection having the lowest chord factor, which is 0.64, operates at 484 volts, which is the highest voltage, while the 8- and 10-pole connections, having a high chord factor of 0.99, operate at 375 and 300 volts respectively. It must be remembered that the speed at which the magnetic field is rotating comes into effect and changes the result of the chord factor. Throughout this series of articles we have considered the induction motor as being an alternating-current generator, generating the counter-electromotive force, or back voltage. Hence, in this case, the assumption has been made that the magnetic field in the air gap remains the same in density for all these connections, and when connected for 4-pole this field will rotate twice as fast as when connected for 8-pole, and thus generate twice as much voltage. This is the reason that the two factors, one due to changing the speed of the field and the other due to changing the throw of the coil, are introduced, as shown in Table III. The product of these two factors governs the voltage which must be applied to the windings to give normal operation.

TABLE III. FACTORS, DUE TO CHANGE IN NUMBER OF POLES, MODIFYING INDUCTION-MOTOR VOLTAGE

Number of poles	4	6	8	10	12
Factor for changing voltage on account of changing speed	1.5	1	0.75	0.60	0.50
Factor for changing voltage on account of change in chord factor = chord factor for new No. of poles ÷ 6-pole chord factor	0.74	1	1.14	1.14	1
Product of Nos. 2 and 3	1.11	1	0.855	0.685	0.50
Resulting voltage = (440 × No. 4)	484	440	375	300	220

Table III determines the value of the proper voltage for the new connections as given in Table I. The horsepower is determined just as if it were an alternating-current generator by taking the product of the volts × amperes × 1.73 × power factor and dividing by 746. The cross-section of the copper has not been changed, hence the amperes remain constant. The power factor is assumed the same, although it will be somewhat higher on high speeds and lower on low speeds. Therefore, the output in horsepower will vary as the voltage, assuming 100 hp. at 440 volts. The horsepower for the new connections is figured in this manner, as given in Table I. Some general observations might be made about the examples chosen in this article: First, the question of starting torque or maximum torque required, or the saturation of the core when connecting for higher speeds might require a voltage somewhat higher or lower than Table I; second, as pointed out in the article in the July 31, 1917, issue of *Power*, on fractional-pitch windings it is not wise, in general, to chord up a coil so far that the chord factor is less than 0.707, which means that the coils span only halfway from the center of a north to the center of a south pole. The reason for this will be shown in the next article by plotting the shape of the magnetic field set up by windings having different coil pitches. For this reason the 4-pole connection, as shown and discussed in this article, should be avoided in practice, but the 6-, 8-, 10- and 12-pole connections would be satisfactory if the proper operating voltage could be secured.

From the foregoing it may be seen that there are three factors to be taken care of in changing the number of poles. These are:

First, if the new speed is to be higher than the original speed, the peripheral speed should not be allowed to exceed 7500 to 8000 ft. This figure is the diameter of the rotor in feet × 3.14 × revolutions per minute.

Second, the chord factor of the winding.

Third, the phase-insulation coils should be shifted so as to come at the beginning and ending of the new pole phase groups, as discussed in the article on "Phase Insulation," *Power*, July 31, 1917.

Sometimes, when a winding is connected in parallel star it is possible to reconnect it in series star with consequent poles, as explained in the Mar. 20, 1917, issue of *Power*, and have the motor operate at one-half its original speed. This reconnection is shown in Figs. 6 and 7. Conversely, if the motor was originally connected for series star, it might be reconnected for parallel star and operate at double speed if the motor would stand up mechanically. The counter-electromotive force generated by the consequent-pole connection is only 86.6 per cent. as much as with the salient-pole connection, which means that if the motor was run on normal rated voltage on the consequent-pole connection it would operate as if it had an overvoltage of $\frac{100}{0.866} - 100 = 15$ per cent. Such a reconnection should not be attempted if the throw of the coils is exactly or nearly full pitch for the high speed. The reason for this will be explained in a future article.

The effect of chording the coils or making the throw less than full-pole pitch, as in Figs. 6 and 7, brings out the point that it is often possible in reconnecting a winding to raise the side of all the coils lying in the top of the slots, and to spring the coils one or two slots longer or shorter and thus help out materially on the operating conditions after the change is made. For example, in Fig. 7, if the coils are raised and wound in slots 1 and 6 instead of 1 and 7, the new chord factor would be sine one-half of $\frac{5}{4.5} \times 180$ deg. = 200 deg., or 0.98 instead of 0.866. The winding connected, as shown in Fig. 7, would then operate as if on 102 per cent. of normal voltage instead of 115 per cent., which would have cut down the iron losses and improved the power factor.

In the next article a graphical explanation will be given of the effect of chord factor and reconnecting for a different number of poles. This will be shown by plotting the shape of the magnetic field set up by a three-phase winding connected for different numbers of poles and whose coils have different pitches. It will show the magnetic conditions inside the motor which give rise to the practical results discussed in this article. As is the case throughout this series no attempt is made to give actual diagrams for all possible changes of poles, but an effort is made to make plain what is physically happening inside the motor in such a way that the practical man may judge for himself the possibility and advisability of any suggested change in connections.

Coal-Pit-Mouth Electric Generation

A burning question of these fuel-short and freight-congested times is the feasibility of burning low-grade fuel at coal mines and delivering electric current to remote markets, instead of transporting the coal to plants near the market for current. As practiced now, coal is loaded on cars needed for other freight, hauled by burning a considerable percentage of it in locomotives, also urgently needed for other service, manned by a labor-short craft, delivered to a city where smoke and dirt are "all sorts of objectionable" and where even the disposition of ashes is a serious problem. What absurdity! Those living in some future period will perhaps wonder what manner of men—engineers—lived in what we now call the "advanced age."

For a long time we have been using pipe lines hundreds of miles long, with relay pumping stations, to handle crude oil from the producing fields to the refineries. The oil men seem to have gone the electricians one better and put it over years in advance.

Protest Power Company Rule

It is becoming the practice of electric-light companies to compel new customers to pay the cost of service connections. According to the *Review*, of East Liverpool, Ohio, the Ohio River Power Co. has adopted such a rule, and the taxpayers and citizens have circulated a petition to be presented to the city council as a protest against this extra charge and to ask the council to use its power to have this ruling discontinued. The company specifies that any person desiring to use electrical currents made by the Ohio River Power Co. shall pay all cost in connection with their lines (this includes time and material) the same to become the property of the company. The petition goes on to state that it is a rule in all cities that the power company shall connect any residence or factory within a reasonable distance of their line free of charge.

The citizens of East Liverpool do not see why they should pay for the installation of connecting line work to their property and then have it become the property of the power company.

Unpreventable Losses in Coal Combustion Under Boilers

BY HAYLETT O'NEILL

Calculations show the relative magnitude of the various unavoidable losses in the combustion of coal under boilers. A number of charts to assist in making these calculations accompany the article.

IT NEVER is possible in the ordinary boiler furnace to transform the total heat units in the coal, as determined by the calorimeter, into equivalent heat of the steam. It is the purpose of this article to show the effect of these losses on the ultimate value of coal for steaming purposes. The necessary losses are due to the following causes:

1. To heating the theoretical quantity of air required for combustion from the outside-air temperature to the uptake-gas temperature.
2. To heating the combustible from the outside-air temperature to the temperature of the exit gases.
3. To evaporating and superheating the moisture in the coal from the outside-air temperature to the boiler temperature.
4. To evaporating and superheating the moisture formed by burning hydrogen at outside temperature to the temperature of the exit gases.
5. To heating the moisture in the theoretical amount of air required for combustion, from the outside temperature to the temperature of the exit gases.

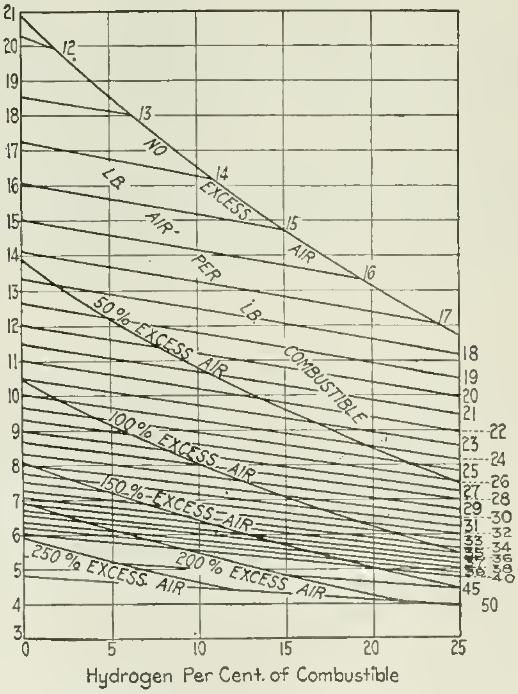

FIG. 1. RELATION BETWEEN HYDROGEN, EXCESS AIR AND CO$_2$

In addition there are other losses practically necessary and due to the following causes:

6. To sensible heat in the refuse to the ashpit with a practical minimum percentage of combustible.
7. To unconsumed combustible in the ash with a practical minimum percentage of combustible.

The effect of climate is obvious, and there will be greater necessary losses in winter than in summer. For example, assume:

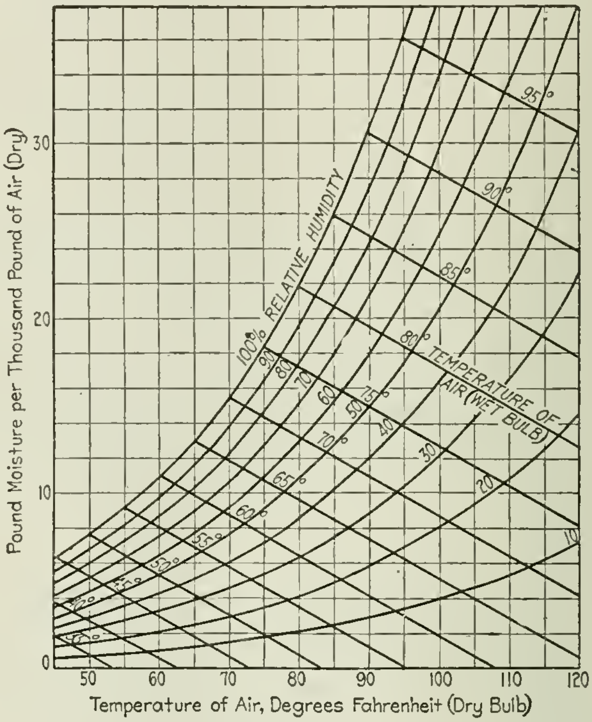

FIG. 2. RATIO OF MOISTURE TO DRY AIR FOR VARIOUS HUMIDITIES

1. Boiler pressure, lb. abs., 165.
2. Boiler-water temperature, deg. F., 366.
3. Outside-air temperature, deg. F., 70.
4. Relative humidity, per cent., 70.
5. Moisture in coal, per cent., 2.
6. Hydrogen in coal, per cent., 5.
7. Practical minimum combustible in ash, per cent., 25.
8. Temperature of ash, deg. F., 1800.
9. Ash in coal, per cent., 6.
10. B.t.u. (dry), per lb., 14,500.
11. Specific heat of refuse and coal, B.t.u., 0.2.
12. Mean specific heat of vapor in atmosphere, B.t.u., 0.46.
13. Dry coal = ash + hydrogen + carbon. This is approximately correct for high-grade Eastern coals—that is, neglecting the effect of sulphur, nitrogen and oxygen.
14. Specific heat of air, B.t.u., 0.2375.

Fig. 1 shows the relationship between percentage of CO$_2$, excess air, and hydrogen contained in the fuel, and the pounds of air per pound of combustible. For average good-grade coal the percentage of hydrogen is about 5. Referring to Fig. 1, with no excess air and 5 per cent. hydrogen, the pounds of air per pound of combustible equal 12.7.

The losses then are as follows:

1. Due to heating theoretical air required:

Air required per pound of coal, $(1 - 0.06)12.7 = 11.92$ lb.

Heat loss per pound of coal, $0.2375 \times 11.92 \times (366 - 70) = 839$ B.t.u.

2. Due to evaporating and superheating moisture in coal[1] (Values from Marks and Dans' Steam Tables):

H at 14.7 lb. abs. and 366 deg. F. = 1223 B.t.u.

h at 70 deg. F. = 38 B.t.u.

Heat loss, $0.02 \times (1223 - 38) = 24$ B.t.u.

3. Due to heating combustible:

Heat loss, $(1 - 0.06) \times 0.2 \times (366 - 70) = 56$ B.t.u.

4. Due to evaporating and superheating moisture formed by burning hydrogen:

Atomic weight of $H = 1$, atomic weight of $O = 16$.

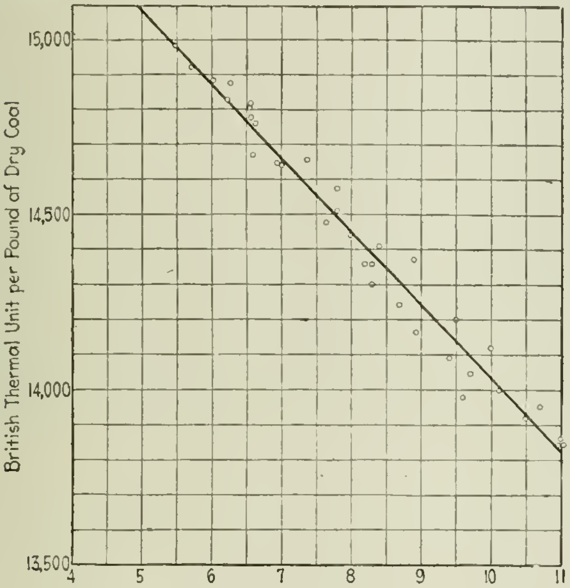

FIG. 3. RELATION BETWEEN ASH AND HEAT VALUE

Pounds of vapor per pound of hydrogen, $\frac{2 + 16}{2} = 9$.

Heat loss, $9 \times 0.05 \times (1223 - 38) = 533$ B.t.u.

Fig. 2 shows the ratio of moisture to dry air for various relative humidities at different air temperatures, as determined by the ordinary dry-bulb thermometer. With 70 deg. F. air temperature and 70 per cent. relative humidity, the moisture per pound of dry air equals 0.0108 pound

5. Due to heating moisture in air:

Heat loss $= 0.0108 \times 11.92 \times 0.46 \times (366 - 70) = 17$ B.t.u.

Total heat loss $= 839 + 24 + 56 + 533 + 17 = 1469$ B.t.u.

From this should be deducted loss due to heating the oxygen required for the combustion of the hydrogen that has been duplicated.

Pounds oxygen per pound of hydrogen, 8.

Heat loss, $0.05 \times 8 \times 0.2375 \times (366 - 70) = 29$ B.t.u.

Heat loss, net total, $1469 - 29 = 1440$ B.t.u.

Maximum possible efficiency $= \frac{14{,}500 - 1440}{14{,}500} = 90$ per cent.

6. Loss due to sensible heat in refuse:

$$\frac{0.06}{1 - 25} \times 0.2 \times (1800 - 70) = 28\ B.t.u.$$

7. Loss due to unconsumed combustible in refuse:

$$\frac{0.25(0.06)}{1 - 25} \times 14{,}610 = 292\ B.t.u.$$

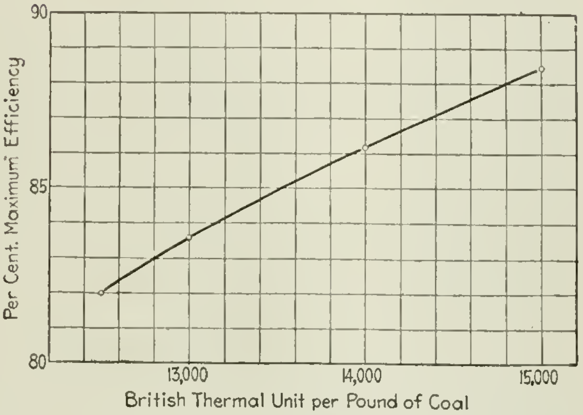

FIG. 4. THEORETICAL THERMAL EFFICIENCY WITH WEST VIRGINIA COAL

Total refuse losses = 320 B.t.u.

Total, all losses = 1763 B.t.u.

Practical ideal efficiency $= \frac{14{,}500 - 1763}{14{,}500} = 88$ per cent.

1. Heat loss on account of warming air:

$$\frac{12.7 \times 296 \times 0.2375(100\ per\ cent.\ ash)}{100}$$
$$= 8.94\ B.t.u.\ (100\ per\ cent.\ ash)$$

2. Heat loss on account of heating combustible:

$$\frac{0.2 \times 296 \times (100\ per\ cent.\ ash)}{100}$$
$$= 0.5920\ B.t.u.\ (100\ per\ cent.\ ash)$$

3. Heat loss on account of moisture in coal:

$$\frac{Per\ eent.\ moisture}{100} \times 1185 = 11.85 \times per\ cent.\ moisture;$$

assume this to be 1 per cent., or 12 B.t.u. constant.

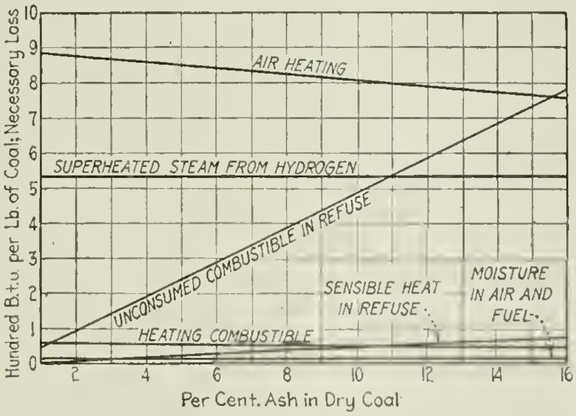

FIG. 5. SEPARATE AND TOTAL NECESSARY LOSSES

4. Heat loss on account of hydrogen = 533 B.t.u.; assume 5 per cent. H.

5. Heat loss on account of moisture in air = 17 B.t.u.; assume this to be constant.

6. Heat loss on account of sensible heat refuse:

$$\frac{Per\ cent.\ ash}{0.75} \times 0.2 \times 1730 = 4.62 \times per\ cent.\ ash;$$

assuming 25 per cent. combustible in refuse.

7. Heat loss on account of unconsumed combustible in refuse:

$$\frac{25}{75} \times \frac{\textit{per cent. ash}}{100} \times 14{,}610 = 48.7 \times \textit{per cent. ash};$$

assuming 25 per cent. combustible refuse.

Summing up all losses, we have:

Necessary losses in B.t.u. = 1486 + 43.8 × per cent. ash.

For good West Virginia coal, analyses taken from a bulletin of the United States Geological Survey show the following relationship between percentage of ash and heat content:

B.t.u. per pound dry is 16,130 — 210 × per cent. ash. This is shown graphically in Fig. 3.

$$\textit{Maximum efficiency} = \frac{\textit{B.t.u.} - (1486 + 43.8\,\textit{per cent. ash})}{\textit{B.t.u.}}$$

Substituting ash in terms of B.t.u.,

$$\textit{Maximum efficiency} = \frac{1.208\,\textit{B.t.u.} - 4832}{\textit{B.t.u.}}$$

This relationship is shown in Fig. 4.

Fig. 5 shows the separate and total necessary losses as calculated.

Cleaning a Condenser With Muriatic Acid

By D. C. McKeehan

The writer once took charge of a 500-kw. plant using a 1525-sq.ft. surface condenser containing 875 three-fourths-inch brass tubes. The plant had been in operation only about six months. Mine water containing a high percentage of scale-forming material was used for cooling, and the tubes were rapidly becoming "plugged." The scale was about as hard as gypsum, so that scraping or drilling was both costly and unsatisfactory. Few of the tubes were clear enough so that a light could be seen through them; only a ¼-in. rod could be pushed through quite a number, and dozens were closed completely. This was about the "limit" for condenser operation, particularly for apparatus in use for so short a time. The problem was to get the tubes clean or at least clean enough to maintain a "reasonably good" vacuum. At times a peak load would pull the vacuum from 19 or 20 in. (the best obtainable at light load) to zero and a clattering of the relief valve could be heard. However, zero vacuum was better than exhausting into the atmosphere, for it allowed the hot condensate to be returned to the boilers—when the pump did not balk; besides, the water was better than usual.

To clear the condenser of scale, it was completely filled with muriatic acid and water, about equal parts, acid being poured in about two quarts at a time, then two quarts of water. The cooling-water intake and discharge openings were of course sealed in order to retain the solution, and to prevent pressure suitable vents were provided for the escaping gas. Occasionally, a violent blowing would occur at the vents, due to the acid opening a tube that contained active material, also due to the increased surface acted upon. The solution was allowed to remain in the condenser until bubbling practically ceased, when it was drained into the circulating pump so that the unconsumed acid might remove the scale from it; and at times it was allowed to pass to the spray nozzles to clean them also. The operation usually required about eight hours, and the treatment was applied every month for about a year. Previous to the recent high price of acid the cost was not excessive, all things considered, and the method of procedure adopted was apparently the most economical available. Operating conditions have changed for the better in the last two years, the tubes requiring cleaning at intervals of two or three months only, as a purer cooling water is available and the pond is allowed to cool from 4 p.m. Saturday until 7 a.m. on the following Monday.

In four years we have removed about 400 tubes and given them individual treatment with acid in a trough, and some were set aside for the scale to air-slack. The percentage of tubes discarded owing to acid attacking the metal is negligible, probably not more than ten. Tubes with longitudinal splits, possibly due to expanding scale inside, number only eight. The corset-lacing packing at tube ends was badly eaten at the end of the first year.

The water-jacket space of the vacuum pump was also cleared of scale by the acid treatment. Then a peculiar turbine vibration suggested that scale or sediment had accumulated on the bottom of the rotor while standing idle. Examination was impossible except at the exhaust end, but these buckets showed a slight coating of dirt and scale. The turbine casing was half filled with a dilute solution of acid and the shaft then turned slowly with a bar. The usual boiling and bubbling sounds were heard inside and rank odors were emitted. When drained of acid and put into service, the turbine acted very well; a subsequent test showed better results, and there was no injurious action on the blading. Kerosene, previously tried, failed to clean the turbine rotor.

Suggestions on the Management of Boilers

By L. R. Hoffman

Assuming a properly installed and equipped plant, the attendant should be a sober, industrious man with enough intelligence to realize the responsibility of his position; he should be well paid and should give heed to the following:

Boilers should be kept free from scale, sludge and soot, inside and outside; frequency of cleaning depends on conditions, but they must be clean at any cost. At least one gage of water should be blown out of a boiler daily, and more as conditions demand. Pop valves should be lifted from their seats at least once a day, and they should be kept clean and free inside and out. Water columns should be blown out at least once a day, noting that the water returns quickly and does not stand dead still; the water should rise and fall gently in the glass at all times. Try-cocks should be blown at least once a day and kept free and clean.

If only one boiler is in use, two steam gages should show the pressure, and when they do not agree they should be inspected and adjusted at once. Sudden contraction and expansion of the metal of a boiler saps its strength. This should be avoided by keeping the feed water going into the boiler steadily, holding the water level near the same place when this is possible.

Government Control of Water Power and Electrical Distribution Abroad

By L. W. SCHMIDT

The writer gives an outline of what has been done in European countries to regulate the production and distribution of electrical energy. Indications seem to point in the direction of increased governmental control of electrical-power production and consumption.

THERE is today possibly no country in the world that has not attempted in one way or another to regulate the production and distribution of electrical power. As to the control of power production, a difference is made as a rule between power generated by steam and hydro-electric power. The reason for this is that while the former has to be regarded more or less as an industrial product, power generated by water is a natural product and therefore more or less the property of the nation as a whole. The systems that have been used for the control of power production and distribution differ very much in each country. Governmental control, where it exerts itself, may begin at the fountain of production, it may be confined to a regulation of the means of distribution, or, finally, it may attempt to control the price of power when sold to the consumer. There are examples of all kinds of regulations among the laws and administrative orders issued in one or another country of the world.

Early Laws Dealing With Electrical Power

The juridical conception of electrical power in the early days of electrical-power control was that of a merchandise produced by a manufacturer and sold to a consumer. Unfortunately for the law makers, this sort of merchandise embodied certain characteristics which necessitated a distribution and consumption different from that of other merchandise sold. The production and distribution of coal gas seemed to be the only precedent. Laws regulating the production and distribution of electrical power, therefore, were framed after the example of the laws dealing with the sale and production of coal gas. This explains some of the measures found in many of the earlier European laws dealing with the control of electric energy, which for a long time hindered the progress of the industry until they were removed by later legislation.

When governments finally came to formulate a policy as to their dealings with the new power, their first desiré was to protect the citizen against the real or imagined dangers connected with its application. The outcome of this generally has been laws dealing principally with the distribution of electrical power. They affect the right-of-way of electrical transmission lines and deal with such questions as protection of private property by falling wires, etc. With the progress made in overland transmission, many of these laws have been strengthened materially, especially as to their safety provisions, and they form today an essential part of the regulations controlling electrical-power distribution all over the world. With the coming of the public utility into the field of electrical enterprise, these laws have been used frequently in support of the public utility against the private electrical enterprise, and it is this side of their application that is of especial interest to the power industry.

This, for instance, is done by the French law of July 15, 1906, regulating electrical enterprise. This law, while providing for the right-of-way for electrical distribution, differentiates between the undertaking having the character of a public utility and such lacking this quality. Each kind of enterprise can obtain a local monopoly as to electric lighting, but only the public utility can claim the additional right of eminent domain. No monopoly is given to either with reference to the production and sale of power only. To prevent the private enterprise from enroaching upon the sales field and thus impeding the action of the public utility, an act has been passed which amends the law by giving a preferential right-of-way to the high-tension transmission lines of the public utilities and semipublic utilities against the ordinary commercial enterprise.

Switzerland Encourages Use of National Water Powers

The same tendency to favor special groups of enterprises is shown in Switzerland, where preferential right-of-way is given to the transmission lines of hydro-electric power stations with the object of encouraging the use of the national water powers for power generation. This Swiss law deals also with transmission lines in general.

Of late Prussia has made an entirely new use of its powers to regulate the transmission. Prussia formerly followed the principle of free development of electrical enterprise, reserving for the government only the right to control the conduct of high-tension transmission lines for which, to use the right-of-way, under the Prussian law, a special permission is needed. The result of this policy has been a rather irregular development of power distribution in Prussia, which often leaves out districts in the immediate neighborhood of the central stations in favor of others farther removed but promising a better financial return. In the absence of a special law Prussia has now decided to use its administrative powers to force the central stations to serve not only the districts where great profits can be obtained, but also those which are less promising but possibly not less deserving. The way selected for this purpose is surprisingly simple.

Right-of-Way for Prussian Transmission Lines

The usual procedure to obtain the right-of-way essential for the conduct of transmission lines is that of application to the provincial authorities. Since 1914 the Ministry of Public Works, which has the direct control of all matters of this description, has decreed that these applications can no longer be passed upon by the provincial presidents, but must be referred to the Minister of Public Works. All applications have to be accompanied by full explanations as to the intended extensions of the installation and the present activity of the central station. Permission for further extensions will be granted only if in line with the special policy followed by the Ministry of Public Works. The Ministry may make its permission dependent upon the condition that the central station, while making the extension, will also make extensions to districts needing supply.

The Netherlands, which has suffered from a similar development of its national electrical supply, has embodied into its new law for the control of electrical enterprise a paragraph reserving to the Crown the right to stipulate the extension or the limits of the distribution field of any licensed electric undertaking. This is done to prevent discrimination in favor or to the disadvantage of certain parts of the country or certain groups of likely subscribers. The law also gives to the government the right to decree the date at which all the districts comprised in the license must be fully connected.

Generally speaking, it appears that the regulation of electrical enterprise by simply exerting control over the distribution of power has not been accompanied by very satisfactory results from the national point of view. The governments realized, in fact, very early the great advantages which industry and public life were destined to derive from the new power. A change took place in the form of governmental control. While all the earlier laws rather inclined toward restricting the use of electricity, parliaments now began to enact measures with a view to aid its expansion. Laws were made giving electrical enterprises certain privileges similar to those enjoyed by railroads and other enterprises of that kind. A series of public-utility laws were made which placed the electrical-power industry in a special, favored position in comparison with other national industries. At the same time a tendency was shown to protect public electric undertakings against destructive competition. Laws, therefore, were passed regulating electrical concessions. Most of the big electrical enterprises having the municipal or public-utility character of today were created during the last twenty years of the past century.

ENGLAND TOOK LEAD IN ELECTRICAL POWER LEGISLATION

The lead in this kind of legislation doubtless was taken by England, which promulgated her first law regulating the generation and distribution of electrical energy during the year 1882. This law gave the control of electrical enterprise in England into the hands of the Board of Trade, which was and still is empowered to issue licenses to municipalities, companies and individuals wishing to operate electrical undertakings. Today the license is granted as a rule after consulting the local authorities, but the board can act without such consultation. According to the law of 1882 the authorities of the locality served had the right to acquire the enterprise after a period of 21 years at 10 per cent. of its value. As it was found that the shortness of this period tended to discourage private enterprise, it was extended to 42 years by the Act of 1888. The Board of Trade exerts considerable powers of control over all electrical undertakings in England, of which the most prominent is the right to review rates. Under a special act of Parliament of 1909 central stations in Great Britain have the right of eminent domain for the conduct of transmission lines and other purposes.

This law of 1882 is doubtless the fundamental law dealing with electrical enterprise today in the whole world. It was the first law that attempted to deal with the production and distribution of electrical power on the basis of a progressive national policy, and it has been copied later in part or in whole not only by most of the British colonies, but practically by all countries of the world. Its licensing provisions are recognized today to be an essential part of all legislation endeavoring to produce the best application of electrical power for the good of all, and there is hardly an agreement made between a public body and a private enterprise for the operation of a public utility in which there is not embodied the right of the licensor to acquire the property from the licensee after the expiration of a certain period with or without compensation to the licensee. As to the right of reviewing rates this is today recognized everywhere.

BRITISH BOARD OF TRADE FAVORS MUNICIPAL ENTERPRISE

While there is nothing in the English law compelling the Board of Trade to follow a certain policy in the issue of licenses to electrical enterprises, it appears from the actions of the board that it has been rather inclined to favor the municipal enterprise. Competition has been allowed to grow in the operating fields of private enterprise, but the municipal enterprise as a rule has been protected against the encroachment of private stations. But allowing even for this preference shown to the public undertaking, it appears that in principle at least the right of free competition has been upheld in England. This right seems to have found its widest application in the policy followed by Italy in dealing with electrical undertakings. In that country electrical enterprises have to obtain a license before beginning operation. This license, however, is obtained apparently without much difficulty, and the result is that there is hardly a city of any size where there are not two or even more electrical stations competing for business.

While competition, therefore, seems to have been held essential to rapid electrical-power development during the last twenty years, it seems that this policy is slowly changing in favor of consolidation of power production with a view to securing a cheaper and more even supply of power over the whole country.

This development has been favored by two considerations. The first has been the increasing use made of the water powers for electric-power generation and the necessity of passing laws for that purpose; the second, the growing demand by industrial and other consumers for the supply of power.

Before considering this last and most recent phase in the development of national power control, the following few examples of legislation dealing with the use of natural water powers in Europe may be given. The Norwegian law recognizes the right of the nation to regulate the use of the water powers of the country, but makes certain exceptions as to such uses of water as do not encroach on the public interest, do not increase or decrease the sea level of inland waters or produce powers above 368 kw. Application for the use of water power can be acted upon by the king provided the withdrawal of water does not exceed 7360 kw. If it is contemplated to use more power, permission can be obtained only by special act of the Storthing. The law does not exclude foreigners from the use of the water powers, but prescribes that concessions given to foreign enterprises as a rule shall not run for longer than sixty years. The Storthing is empowered to extend the duration for another ten years. In every case the nation reserves the right to acquire the property of the licensee after forty years of operation. No payment need be made in such a case where the acquisition takes place after fifty years of operation. The use of water power is dependent upon the payment of a license fee.

The French Water-Power Law

Very similar to the Norwegian water-power law is that of France. This law demands in the case of developments of less than 200 kw. a simple governmental authorization which is issued, as a rule, without much trouble to the applicant. Developments of 200 to 5000 kw. require a special governmental decree, while higher developments can be carried out only under a special law. The maximum duration of an authorization is 75 years, but the concession may be extended for another ten years if no new concession has been granted five years before the expiration of the original grant. The government reserves the right of expropriation after a period of fifteen years' duration of the grant if such action is in the public interest.

Similar action for the protection of the natural power resources has been taken by most of the South American governments. The water-power law of New Zealand represents today the final stage in this development reached so far by reserving the right of all hydro-electric development to the nation. The Dominion is now developing the most promising power sites under national management.

So far Europe does not seem to be ready to go all the way in the direction of public ownership of national power production. Nevertheless, it becomes now increasingly clear that future legislation in Europe destined to deal with the problem of power production and distribution will be vastly different from the policies followed before the war. It is generally held in Europe that electrical-power production has passed the stage of the public utility and reached that of national utility.

Prussian Government Adopts New Policy

The Prussian government only recently struck out for a new policy in hydro-electric power development by which it enters into direct competition with the existing private and municipal generating stations with the avowed intention finally to take control of the whole power generation in Prussia. So far the scheme provides for a system of interconnected hydro-electric and steam power stations owned by the Prussian government which will cover all of western Prussia from Bremen to the Main. The interesting feature of this scheme is that the different stations have been selected in such a way as to supplement one another. If, as it is expected, the station on the Main should suffer in effectiveness during the months of February and March, its losses can be equalized with the help of the two stations at the Elderthal and the Diementhal reservoir, where sufficient power will be obtainable for this purpose. Another hydro-electric station, according to press reports, is located at Dorverden. This, like the others forementioned, will be connected with the steam-power plant near Hanover, where the great peat coal beds of the neighborhood can be employed as a cheap fuel.

This Prussian system of power supply is continued in the south by a similar development in Bavaria. The center of the Bavarian scheme is the powerful government central station on the Walchensee. For the purpose of this enterprise it is proposed to combine all the power stations existing at present in Bavaria, the new combination to be conducted under governmental control. The Walchensee development will be connected with the most powerful of the other stations, and these together will be the principal sources of electrical power in the kingdom, while the small stations will continue to act merely as distribution stations for the central system. It is expected that such an organization would save approximately 20 per cent. on the present operation expenses, or about $1,000,000 a year.

France also will make a better use of its natural power resources after the war. It appears that so far no special legislation has been passed for this purpose, but a commission has been appointed to inquire into the existing hydro-electric possibilities of the country with a view to early exploitation.

England Adopts the Most Extensive Scheme

The most extensive scheme for national power control so far developed, however, has been put forward in England. The industrial reorientation in England forced by the war has provided for the opportunity also to reorganize the whole system of power supply in that country. According to the present scheme, which was worked out by a combined committee of the Municipal Electrical Association and the Incorporated Association of Electrical Power Companies, it is contemplated to divide England and Scotland into sixteen supply areas. These areas will not be formed by political divisions, but their boundaries will be defined rather by technical considerations so that the best results may be obtained in the distribution of power. In each area the production of power will be concentrated in such a way as to allow the closing down of all the generation stations that are not absolutely essential. The remaining stations will be interconnected to obtain a better equalization of the load over the operating district. It is thought that it may be possible to use most of the existing large power houses. Should additions be necessary, it is proposed that new power houses be erected in neighborhoods where special facilities are offered for their operation.

While all power experts in England seem to agree that the concentration of power generation in the form prescribed by the report finally will be the most satisfactory solution of England's power problems, public opinion is not as unanimous about the recommendation of the committee to exert the same control on power distribution. Most probably this will be left in the hands of the existing enterprises. Estimates seem to show that by reorganizing in this way the production of electric power, it will be possible for England to effect a saving of approximately 50 per cent. in the cost of electricity to the consumer. All in all about six hundred central stations would be affected by the scheme. The control of the enterprise will be in the hands of a national board of control.

As the existing powers of the Board of Trade will not be sufficient to carry into effect so vast a scheme of electrical organization, it will be necessary to obtain special powers by act of parliament, and the whole enterprise, therefore, will be discussed fully before being actually put into operation.

In Europe the war has been the principal cause of the reforms now contemplated. It is, however, certain that even if the war had not come, steps very soon would have to be taken for a reorganization of the legislation governing electrical-power production and development. The great progress made in the electrometallurgical and the electrochemical industries has widened the application of electrical power in such a way as to necessitate the employment of power which could not be foreseen originally by power experts and law makers. The war now has prepared a fertile ground for a new settlement of the whole question of power control. What will be the solution of the problems raised is still not quite clear. In Europe all indications seem to point in the direction of increased national control of electrical power in all its stages from production to consumption.

Boiler-Room Gage and Control Board

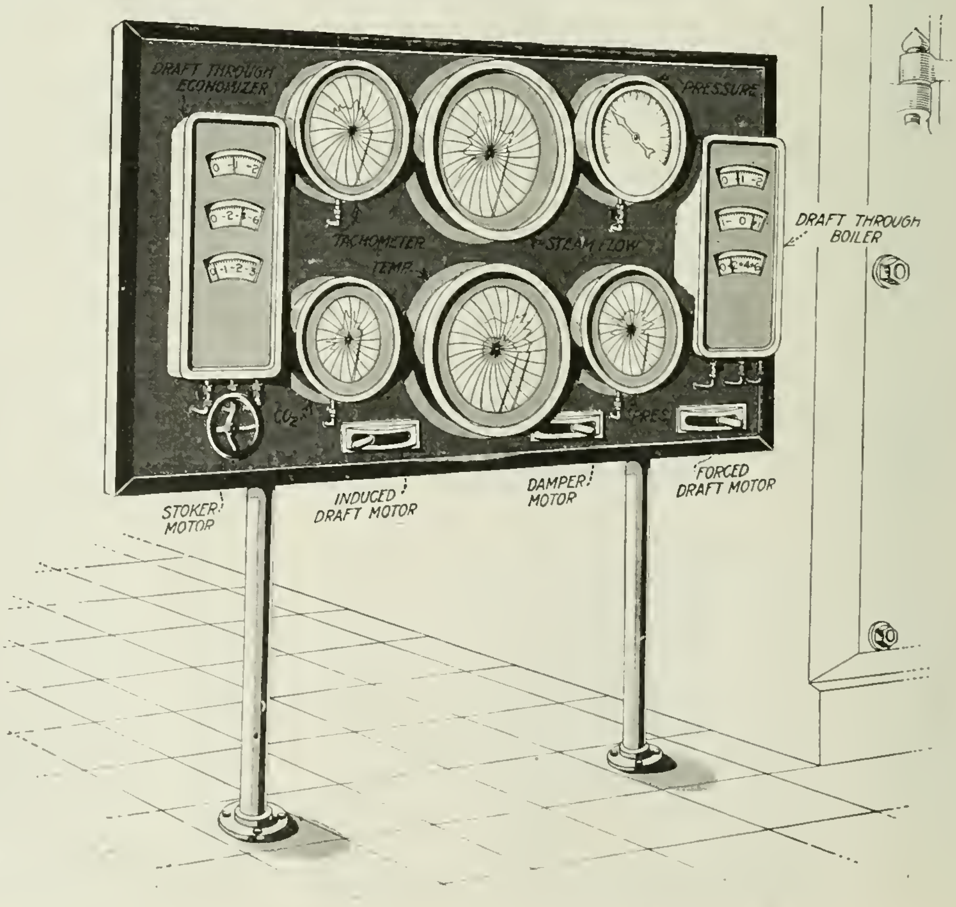
Centralization is the basis of economy in any branch of industry. A machinist would make but little progress in turning out his allotment of work if he were obliged to go from one side of the shop to the other each time he required a tool. In the power plant a fireman will be able to obtain better results from his boilers if the various gages, draft-fan control and other necessary operating devices are placed convenient for observation and manipulation instead of being scattered about the boiler room wherever it is most convenient to place them.

The idea of centralization has been adopted by the Precision Instrument Co., Detroit, Mich., in the design of a boiler-room gage and control board illustrated herewith. The recording gages include a tachometer for recording the speed of the stoker and a steam-flow meter for recording the steam flow in the main steam header leading to the power unit; there is also an indicating steam gage. These are arranged at the upper portion of the board; at the lower end there is a CO_2 recorder for furnace gases, a double-pen recording gage for furnace- and chimney-gas temperatures and a recording steam-pressure gage. At the right-hand end of the board there is a three-in-one draft gage that indicates the standard readings of the furnace draft which has a register of from zero to 2 in. of water for the flue; 1 in. vacuum to 1 in. pressure for the combustion chamber and from zero to 6 in. for the ashpit. These readings are shown on the boiler-draft gage beginning at the top of the instrument and reading downward.

At the left of the gage board is another three-in-one draft gage for indicating the draft through the economizer. The top gage is connected to indicate the draft in inches at the chimney, the center one shows the draft through the economizer, and the bottom one the draft at the entrance to the economizer when one is used.

Centralization of the motor control is also taken care of as shown by the handwheel and the switches at the bottom of the gage board. The handwheel at the left controls the rheostat of the motor that operates the stokers. Next to it is a switch for starting and stopping the induced-draft fan motor; the center switch is to control the motor used for opening and closing the main damper in the smoke flue, and the last switch is for controlling the motor that drives the forced-draft fan.

This gage board is supported on standards, and it can be placed at any point in the boiler room where the operator can conveniently get at it for operating the various controls and for reading the various instruments.



GAGE AND CONTROL BOARD FOR THE BOILER ROOM

The Electrical Study Course—Shunt-Connected Generators

Explains how an electrical generator builds up its voltage from the small pressure that is generated due to the residual magnetism in the polepieces. The relation that must exist between the field coil and armature connection for the machine to generate normal voltage is also pointed out.

IN THE previous lesson we considered that the field coils of the generator were excited from an outside source; that is, as in Fig. 1, the field coils are assumed to be connected to some source of electric current, for exciting them, separate from the armature. In alternating-current generators the field coils are always excited from a separate source of direct current, but in direct-current generators the field coils are in almost all cases excited directly from the armature. There are two ways of doing this, one by connecting the field coils directly across the brushes—that is, the field winding is in parallel with the armature, as in Fig. 3—and another by connecting the field coils in series with the armature, as in Fig. 4.

When the field coils and armature are connected in parallel, as in Fig. 3, the machine is known as a shunt-connected generator; when the field coils and armature of a generator are connected in series, as in Fig. 4, it is known as a series machine. The shunt-type machine, or modifications of it, which will be considered later, is the type that is generally used, the straight series type being seldom used and then in only special cases. To simplify the connection in Fig. 3 and subsequent figures, the commutator will be shown on the outside of the winding and the yoke will be dispensed with.

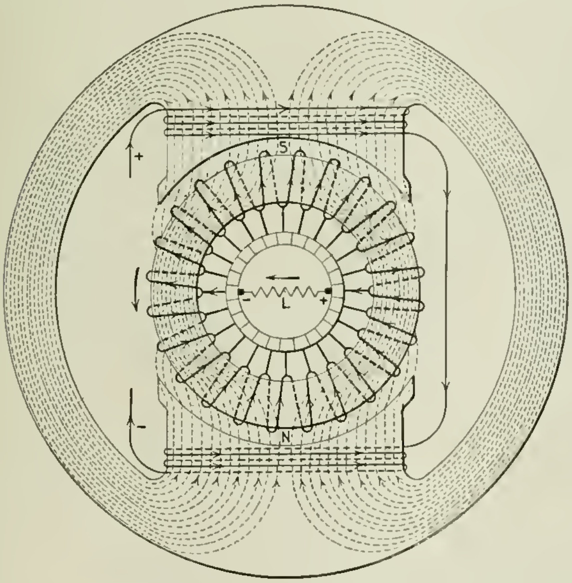


FIG. 1. SEPARATE-EXCITED SHUNT GENERATOR

With the machine that excites its own field coils, the first question that arises is, How does the machine start to generate? If the machine was new and never had been in service before, it would not generate until an electric current had been caused to flow through the field coils to magnetize the polepieces. When the field poles have been magnetized, they will retain a small percentage of the magnetism after the current has ceased to flow through the field coils. This generally amounts to about 5 per cent. of the normal field magnetism. The magnetic flux which remains in the field poles after the current has ceased to flow in the coils is called the residual magnetism. This residual magnetism is sufficient in a 110-volt machine to cause about 5 or 6 volts to be generated in the armature when running at normal speed and with the field coils disconnected from the armature, as in Fig. 5; in a 220-volt machine, approximately 10 or 12 volts will be generated due to the residual magnetism.

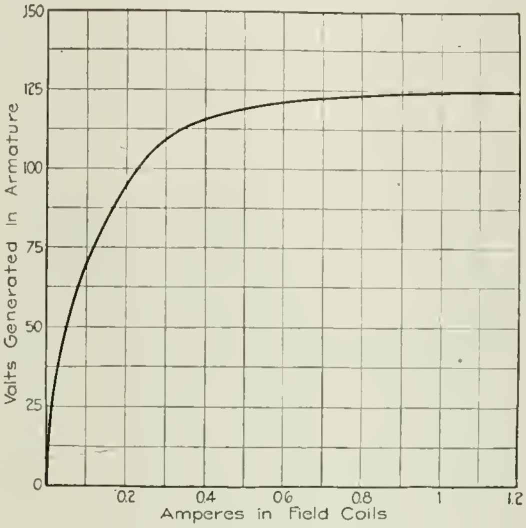

FIG. 2. DIRECT-CURRENT GENERATOR VOLTAGE CURVE

If the field coils are connected across the armature, as in Fig. 3, and the latter revolves in the direction of the curved arrow, a small voltage will be, as pointed out in the foregoing, generated in the armature windings. This small voltage, say 5 volts, will cause a small current to flow through the field windings; if in the proper direction, it will cause the field strength to be increased above that of the residual magnetism.

In Fig. 3 the polarity of the residual magnetism is denoted by *N* and *S*, which will, for the direction that the armature is turning in, cause the right-hand brush to have positive and the left-hand brush negative polarity. This in turn will cause a current to flow through the field coils in the direction indicated by the arrowheads. By applying the rule for the polarity of a coil of wire with an electric current flowing through it, it will be found that the field coils will have a polarity as indicated by *N'* and *S'*, which will be seen to be the same as the residual magnetism in the polepieces. Consequently the current flowing in the field coils will assist in magnetizing the polepieces, and the small current set up in the field coils by the 5 volts, which we assumed was generated due to the residual magnetism in the polepieces, will increase the field strength; that is, there will be a greater number of lines of force entering and leaving the armature. The armature will therefore be cutting a greater number of magnetic lines, hence causing the voltage to increase, which in turn will cause the field current to increase, thus bringing about another increase in the field flux and also the voltage in the armature. This process continues until the machine is generating full voltage.

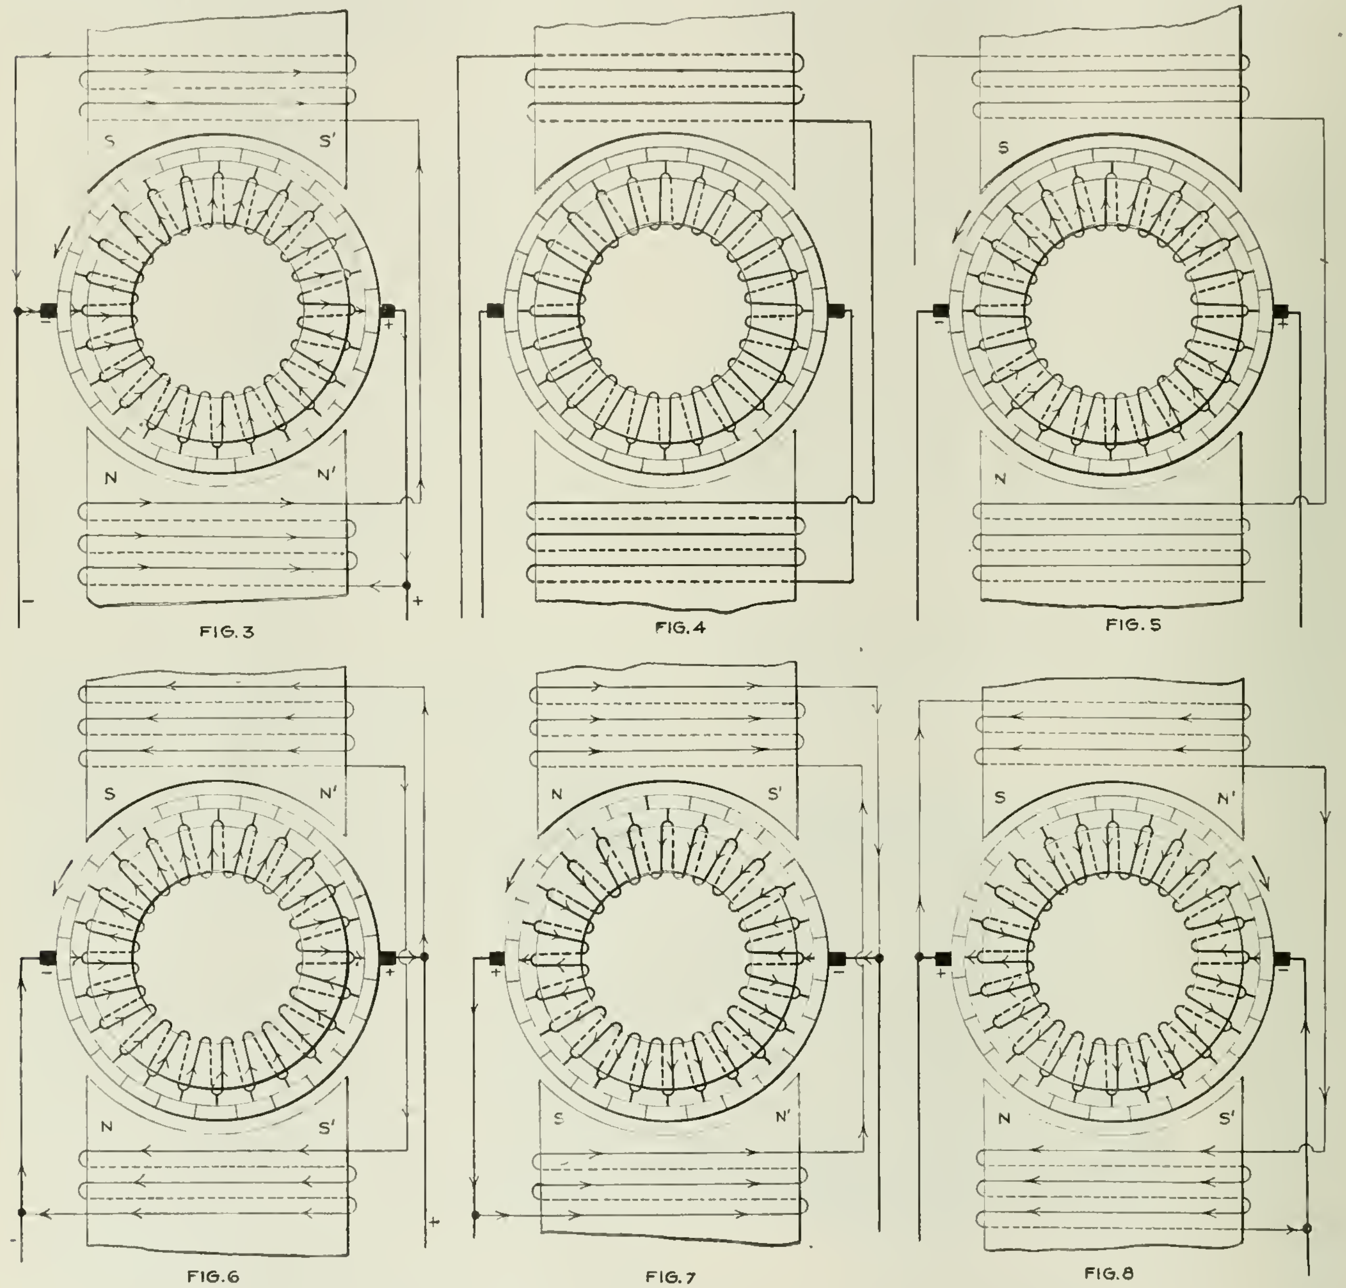

FIG. 3 FIG. 4 FIG. 5

FIG. 6 FIG. 7 FIG. 8

FIGS. 3 TO 8. DIAGRAMS OF SHUNT-CONNECTED AND SERIES-CONNECTED GENERATORS

The next question that naturally arises is why this process does not keep on indefinitely and the voltage continue to increase in value. The answer to this is found in the fact that the lines of force in the field poles do not increase in proportion to the current flowing through the coils.

If we were to take a generator with the iron in the magnetic circuit absolutely dead, that is, no residual magnetism in it, and connect a voltmeter across the armature terminal and drive the machine at normal speed, it would be found that the voltmeter would give no reading, indicating that no voltage was being generated. However, if the field coils are connected to a separate source of voltage and a small current caused to flow through the field coils, say 0.2 ampere, we would find that the generator would produce an electromotive force of, say 90 volts. Then if we were to increase the current to 0.4 ampere, it would be found that the voltage may not increase as much for the second 0.2 ampere as it did for the first. This, however, will depend somewhat upon the normal voltage of the machine. In this case assume the normal voltage to be 110 and that when 0.4 ampere was flowing in the field coils, the machine generates 115 volts.

The foregoing is indicated on the curve Fig. 2. Here it is shown that if the field current is increased to 0.6 ampere, the volts will only increase to about 120, and beyond this point if the current is increased to 1.2 amperes, the voltage only increases to 124. For the first 0.6 ampere supplied to the field coils the voltage increases from 0 to 120, but for the next 0.6 ampere the e.m.f. only increases from 120 to 124, or an increase of 4 volts. The foregoing indicates that the lines of force in the polepieces increase rapidly at first, but as the current in the field coils increases, a condition is reached beyond which increasing the current in the latter will not cause any increase in the lines of force. This condition is called the point of saturation; that is, the iron is saturated with magnetic flux, just the same as a sponge becomes saturated with water.

A fixed relation exists between the connection of the field winding to the armature and the direction of rotation. It has already been shown that the field-coil connections to the armature in Fig. 3 are such that the current flows through them from the armature, in a direction to make the field coils the same polarity as the residual magnetism in the polepieces, thus causing the machine to build up to normal voltage. However, suppose we interchange the field-coil connections as in Fig. 6. In this case the polarity of the field coils, as indicated by *N′* and *S′* is opposite to that of the residual magnetism, indicated by *N* and *S*. Consequently, instead of the small current caused to flow in the field coils by the voltage generated due to the residual flux, increasing the field strength, it has the opposite effect and the machine cannot build up its voltage.

At first thought it may appear that if the polarity of the residual magnetism is reversed, the machine connected as in Fig. 6 could build up. Considering Fig. 7 will show that this is not true. Since the residual magnetism is reversed, as indicated by *N* and *S*, the voltage generator in the armature is reversed; consequently, the current in the field coils is also reversed, as indicated by the arrowheads. This again brings the polarity of the field coil, as shown by *N′* and *S′*, opposite to that of the residual flux, and the machine cannot build up. Therefore it is evident that for the direction of rotation shown there is only one way that the field coil can be connected to the armature and have the machine generate, and that is as in Fig. 3.

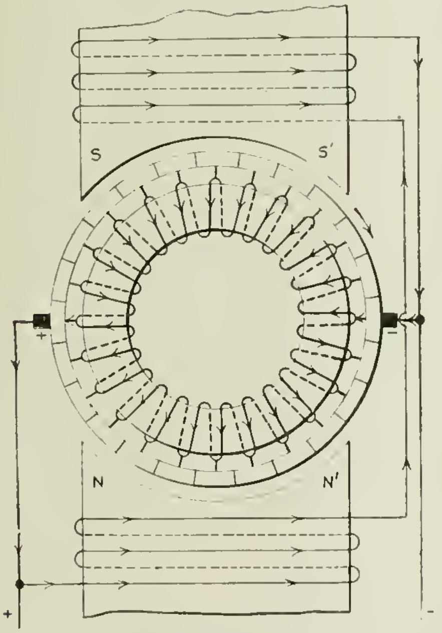

FIG. 9. SHUNT-CONNECTED GENERATOR. SAME AS FIG. 8 WITH FIELD CONNECTIONS INTERCHANGED

If the armature's direction of rotation is reversed, as in Fig. 8, then the field-coil connections to the armature have to be reversed before the machine can build up. Assume the same polarity for the residual magnetism as in Fig. 3; then, since the direction of rotation is reversed in Fig. 8, the voltage generated in the armature winding will be reversed, as indicated by the arrowheads. This voltage will cause a small current to flow through the field coils in a direction as shown, which gives the coils a polarity *N′* and *S′* which is opposite to that of the residual flux, and the generator cannot build up to normal voltage.

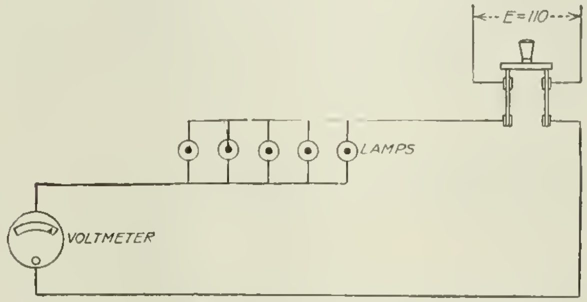

FIG. 10. DIAGRAM OF LAMP BANK CONNECTED IN SERIES WITH A VOLTMETER

To produce a condition where the machine can build up its voltage, it will be necessary to interchange the field connection to the armature terminals, as in Fig. 9. This allows the small voltage due to the residual magnetism to set up in the field coils a current that will give them the same polarity as the residual flux, as shown, and the machine will build up to normal voltage.

The foregoing is an important point to remember when putting into service a new machine or one that has been repaired. After the field poles have been excited by sending a current through the field coils from an outside source, to establish the residual magnetism, if the machine does not build up, then the shunt-field coil connection should be reversed.

One way of knowing when the field coils are connected in the right relation to the armature is as follows: First bring the machine up to normal speed with the field coils disconnected from the armature and note the voltage generated, which should, as pointed out in the foregoing, be about 5 or 6 for a 110-volt machine, 10 or 12 for a 220-volt machine, etc. After doing this connect the field coils to the armature, and if the voltage due to the residual magnetism decreases, the field-coil connections must be reversed for the machine to come up to normal voltage. Further consideration will be given the shunt generator, also the series generator, in the next lesson.

Fig. 1 is similar to the problem given in the last lesson. The two circuits through the armature from the negative brush around to the positive are in parallel, and each path was assumed to have 0.5 ohm resistance. Therefore, the resistance of the armature winding between brushes is one-half that of one path, or $0.5 \div 2 = 0.25$ ohm. The external resistance was assumed to be 4.75 ohms; then the total resistance of the armature and external circuit is $R = 0.25 + 4.75 = 5$ ohms.

When the armature is generated a voltage $E = 150$, the current flowing in the circuit is $I = \frac{E}{R} = \frac{150}{5} = 30$ amperes. This current will divide at the negative brush and one-half will flow through each of the two circuits in the armature winding. Consequently, each half of the armature winding will supply 15 amperes to the external circuit. The volts drop in the armature equals the joint resistance of the winding times the total current, or $0.25 \times 30 = 7.5$ volts. The volts drop also equals the resistance of one path through the armature winding times the current flowing in this path, or in this case $0.5 \times 15 = 7.5$ volts. If 7.5 volts is used up in the armature to cause the current to flow through the winding, then only $Ea = 150 - 7.5 = 142.5$ volts is available at the brushes. The current that Ea will cause to flow through the external circuit the resistance of which is $R' = 4.75$ ohms, is $I = \frac{E_a}{R'} = \frac{142.5}{4.75} = 30$ amperes, which checks up with the values obtained in the foregoing.

The value of one of two resistances connected in parallel is 6 ohms; the joint resistance of the two is 3.75 ohms and the resistance of the voltmeter is 10,956 ohms.

In Fig. 10 if the resistance of each lamp is 220 ohms and the resistance of the voltmeter is 10,956 ohms, what will the reading of the voltmeter be? Also will the lamps light, and if not, why not?

Coal Conservation Without Shutdown of Isolated Plants

THE continuation of the hearing before the Public Service Commission for the First District of New York on Mar. 18 was rendered unusually interesting by the testimony of C. T. Coley, who appeared for the New York Building Managers' Association. Mr. Coley, who is operating manager of the Equitable Building, proposed a plan whereby the isolated plant for combined lighting and heating could be operated in conjunction with the public-utility plant with a maximum of benefit to the community. The plan involved three suggestions, the common object of which was to save coal without detracting from the value of the various kinds of service.

According to Mr. Coley's argument, the seasons of the year may be divided into three groups, the first group being the winter months of December, January and February, the second group being the six months comprising spring and fall, and the third group being the summer months of June, July and August. A few buildings containing isolated plants produce insufficient exhaust steam from the manufacture of power or electric energy to heat themselves during the three winter months, and it is necessary to draw further on the coal pile by generating live steam, which is turned into the heating system so as to maintain the desired temperature. This is especially true of mornings, nights, Sundays and holidays. The remedy for this condition is to increase the electric production to a point at which enough exhaust steam will be produced to meet the heating requirements and to find a suitable outlet for the excess current generated.

Obviously, the extra energy produced must be used in such places as to save coal or to remove the necessity of burning coal. Two methods of accomplishing this result are suggested. First, to obtain permission to supply other buildings in the neighborhood—across the street, if necessary—with electricity, thus reducing their demands for energy on the Edison company's mains at such times; and second, to run separate units on independent busbars in the isolated plant and synchronize with the 240-volt direct-current mains, pumping electrical energy from the isolated plant out on the Edison company's mains and using the additional exhaust steam thus produced to make up the deficit for heating in the coldest weather.

To illustrate the amount of coal needed for live-steam generation for heating, in addition to the exhaust steam used, Mr. Coley submitted the following statistics of coal consumption in the case of the Equitable Building:

Month	Coal, in Lb.	Kw.-Hr.	Coal per Kw.-Hr.	
June, 1917	2,940,490	456,896	6.49 Aver.	6.43
July	2,982,080	496,034		6.01
August	2,928,690	461,329		6.34
September	2,913,120	416,866		6.98
October	3,201,030	475,962		6 72
November	3,205,150	411,562		7.78
December	3,826,190	405,129	9.09 Aver.	9.44
January, 1918	3,255,700	358,678		9.07
February	2,634,500	300,401		8.76

The second column shows the total coal used per month; the third column shows the electrical output; and the last column shows the pounds of coal used per kilowatt-hour for all services. During the first five months shown, the average coal used per kilowatt-hour was 6.49 lb., which was about the normal summer rate. During the three winter months an average of 9.09 lb. of coal was used per kilowatt-hour for all purposes. The increase, 2.60 lb. per kilowatt-hour, is due to heating requirements.

The electrical output during the three winter months was 1,064,208 kw.-hr. Then, $(1,064,208 \times 2.6) \div 2000 = 1383$ tons of coal, which was burned in excess of that required to produce the electrical energy so as to furnish live steam to help out in heating the building.

If this 1383 tons of coal had been used to generate electrical energy, and the exhaust had then been used for heating, it would have been possible to supply to the Edison company's 240-volt mains 553,200 kw.-hr. during the three winter months, assuming 5 lb. of coal per kilowatt-hour. Thus, the coal saved to the community as a whole would be the amount required at the Edison plant to produce that 553,200 kw.-hr. As a central station can produce a kilowatt-hour on 2 lb. of coal, or two-fifths of the quantity used in the isolated-plant calculation, the net saving of coal would amount to two-fifths of 1383 tons, or 553 tons.

The second suggestion for coal saving made by Mr. Coley was that during the months of March, April, May, September, October and November the isolated plant should be allowed to supply electric energy, and particularly exhaust steam, to its neighbors, whether over the street or under it. During these months some exhaust steam is used for heating, but at the same time great quantities are wasted into the atmosphere, while buildings close by are buying steam for heating or are producing it in their own heating boilers, merely because of lack of permission to run mains under or over streets. Much coal could be saved to a community if it were permissible to supply exhaust steam from engines to buildings across street and such permission should be granted as a war-emergency measure, if not permanently.

The third suggestion was that the Edison company should make a low-rate schedule to apply during the summer months of June, July and August, and maybe include May and September also, to enable isolated plants to shut down for this period and thereby save an amount of coal equal to the difference between what they would burn and what the Edison company would burn to furnish the electrical energy they needed.

Holding Plant Labor in Nonheating Season

It was pointed out by Mr. Coley that although isolated plants could be shut down during the nonheating period, it would not be feasible to discharge the operating forces; for if that were done, the men thus thrown out of positions would turn to other forms of labor, and there would be great difficulty, if not an actual impossibility, of getting trained men to put the plants into operation again at the beginning of the heating period. The men would have to be retained throughout the summer, and their services could be utilized in making overhauls and repairs to the plant equipment. On this account, any rate for that period made by the Edison company would have to be considered from the coal pile in order to be economic and would have to take into consideration the retaining of the plant operatives.

The impossibility of saving coal by substituting central-station current for that generated in an isolated plant having use for exhaust steam was further emphasized by the testimony of H. Goldstein, who operates two manufacturing buildings in which steam is required from 9:30 a.m. to 6 p.m. The steam is used for power, lighting, heating and various manufacturing processes. According to this witness, the cost of operating one of the buildings by purchasing Edison company current and generating live steam in his own plant amounted to $1000 a month. Later, he installed an engine and generator of sufficient capacity to furnish electric current to the tenants of both buildings, and discontinued the use of Edison company service, with the result that at present he is supplying current and steam to both buildings at a monthly expense of only $700.

Robert E. Dowling presented the cases of the Adams Express Co. building at 61 Broadway and the City Investment Building, in each of which is an isolated plant for furnishing light and heat. Neither building has any electrical connection with the Edison company. The average coal consumption in each building is in the neighborhood of 35 or 36 tons per day, the exhaust steam from the engines being ample to furnish heat for the buildings. If current were obtained from the street service during the warm weather, much of this coal would be saved; but during the seven months in which heating is required, the cost of running the plants to furnish heat would be equal to the present cost for combined current and heating, since all the exhaust is available for heating purposes.

Arthur F. Rice, representing the Coal Merchants' Association, deprecated the shutting down of isolated plants during the warm months, on the grounds that the coal man must have something to do in the summer if he is to maintain his facilities for winter deliveries. He insisted that no coal dealer could afford to keep his men, horses and trucks on the basis of a winter business only.

The hearing will be resumed on Apr. 8.

Unit Costs of the Cleveland Electric Illuminating Company

The table shows the unit costs of the Cleveland Electric Illuminating Co., as shown by Ballard Exhibit No. 6 in the Cleveland Electric Rate Case before the public utilities commission of the State of Ohio on Feb. 20, 1918.

These values are classified figures taken from Nau Audit, Commission's Exhibit No. 2, and reduced to cents per kilowatt-hour sold by F. W. Ballard & Co. These figures will be of general interest to engineers and city officials.

It should be noted that the unit cost for practically every classification of expense has decreased during this four-year period, notwithstanding the fact that the cost of labor and material has increased owing to war conditions. The kilowatt-hours sold during the four years was: 1913, 123,767,142; 1914, 167,226,182; 1915, 180,800,669; and in 1916, 248,465,487.

Secretary Lane Supports the Water Power Bill

He Points Out That Water Power Will Not Be Developed Under Revocable Permits, but That Long-Term Leases with Fair Recapture Provisions Furnish a Workable Plan

SECRETARY LANE of the Interior Department appeared at the hearing on the Administration water-power bill before the Joint Special Water Power Committee of the House of Representatives in Washington Wednesday, Mar. 27. After pointing out that the bill now before the committee has a long history and reciting some of the attempts to bring about water-power legislation during the last five years in which he and others have been concerned, Secretary Lane said that the matter of developing one bill in Congress was taken up, and that there was strong opposition in some quarters against any kind of leasing system. "Perhaps a very considerable portion of the time I have devoted to this matter," he said, "has been spent in attempting to convert members of the House and Senate, who had notions in opposition, that the leasing system was the only practicable one."

Revocable Permits Unsatisfactory

The Secretary pointed out that there is still on the books a statute under which revocable permits are granted, but that the men who have money to invest in water-power propositions are not willing to allow any official to say when the investment they have made shall be thrown to the winds. The result, he said, has been that "we have stood for five years of which I know almost entirely without development of one of our great resources. Now, it is not merely the West that is concerned in this; it is the East just as well. Right now I can call your attention to one particular matter that shows how intimately East and West are tied up on such a proposition. You know John D. Ryan, of the Montana Power Co. He has private rights, or his company owns certain dam sites and rights along rivers in Montana. I sent out a general request some time ago that the Eastern minerals which had not been heretofore developed in very great quantities, such as manganese and chrome, should now be developed for the purpose of saving ships. We get manganese, as you know, from Brazil. It takes a very large tonnage. We import some 800,000 tons a year. We get chrome from Africa and New Caledonia. We get nitrates from Chile, and for all those things a very large number of ships are at present required. We are short, the Allies are short, for the carrying of nitrates to the other side and to this side, . . . short for carrying pyrites from Spain to this side, . . . short for carrying manganese from Brazil, . . . short for carrying food to our own boys on the other side, and munitions and food for the Allies; and no matter what comes out of this German drive now going on over there, there is an obligation upon us, and the pressure of necessity that we should supply those people on the other side.

"For that we must have ships. Now, Mr. Ryan came to me and said he had a plant in Montana which will develop 150,000 hp. That horsepower can be used in a process by which the low-grade manganese ores we take out of the Butte mines can be reduced, and by their reduction they can be made commercially available to the plant in Pittsburgh. So that a water power 2000 miles away in Montana makes possible the development and the support of industries in Pittsburgh and relieves ships that come all the way from South Africa."

Secretary Lane then again went into the history of the various bills that have been before Congress and said that the executive branches of the Government, in the present bill, had united upon a measure under which "leases could be made that would govern the navigable waters and the unnavigable waters, and control as to public lands and as to forests." He told the committee he felt sure its members would find the House and the Senate in support of a measure, such as that under consideration, which does the following:

"Gives a lease for a definite term of years not to exceed fifty years; gives an opportunity for the Government to take over the property at the end of that period; gives an opportunity if the Government does not want to take over the property at the end of that time for the lessee to take it over, and I should say that reasonable terms to him would be that he should have that property if the Government does not wish to use it and that he should have that property upon terms that would be no more favorable to him than those that others might offer, but that he should have a preference. . . . Into the hands of the men capable of developing them should be given sufficient to make a wise and large investment and development; we cannot save things for men who have no capital or men who go about things with a spade where a steam shovel is needed."

Right of the People Is Paramount

The Secretary spoke of the right of the community, of the nation, pointing out that the right of the people of the United States is superior to any right "that you or I might have to speculate upon those things that are primary resources," and adding that he believes as to lands and as to minerals and as to water powers that no man is entitled to anything unless he uses it.

"If we had money enough," he continued, "if this were not a time of war, if we could think in the terms of money that we are now thinking of, or if four or five years ago Congress had been willing to expend hundreds of millions of dollars in the development of water power as it is forced now to spend millions of dollars for war, it would be a wise thing to put a large part of the public revenues into such projects where they are found to be needed.

"I have no doubt in my own mind but that such schemes as water-power schemes are perfectly practicable from a Governmental standpoint, no matter what your sympathies may be respecting Government ownership, as a rule, of large utilities. A thing that is as well standardized as a water-power scheme can be operated successfully by the Government. But I do not take it that this is a practicable proposition at this time, nor probably will it be for many years to come, and it is necessary that there should be real development, and that soon." Mr. Lane elaborated his point of view in regard to the impracticability of devoting Government funds at this time to the building of water-power plants by discussing the immense demands being made upon the Treasury now and in prospect.

"The news now coming from the other side of the water," he said, "is disheartening, discouraging, but it leads me to believe that all the conclusion we can come to is that we are in this thing for a longer time than we thought. Not that there is to be any cessation of effort on our part, but there is to be renewed effort, a stronger fight, and a longer fight. And if we are to have a long fight, and if we are to get into this thing with our full strength; if a larger portion of the burden of beating von Hindenburg and the other Germans is to fall upon us, then, surely, it becomes necessary that we should not delay longer in the development of every resource that we can."

Secretary Lane spoke at this point again of the nitrate situation, pointing out that it is not one that can be looked upon with equanimity and remarking that "the more nitrates we have the more food we can get," as well as "There is a large portion of the acreage of this country that is now coming to need fertilizers of one kind or another."

The speaker then told of an offer he had had from a company in Washington five years ago for the development of a water-power proposition. "That proposition," he said, "could have been financed successfully at that time if we had had such a bill as the one which is now before you. Then they wished to go into the business of developing nitrates. The power is still there and is still unused." He said that there are propositions of this kind all over the country, that there is a supreme obligation upon all the people of the country at this time, as well as its officials, to think more seriously of such things, and that "we will get no development under the present law."

Not in Sympathy With Government Loans to Private Enterprises

Answering questions by Chairman Sims, Secretary Lane, before entering upon a general discussion of his remarks, participated in by almost all members of the committee, said that if there is a determination by Congress that there shall be water-power development—for instance, along the Columbia River, or the Snake River, or the Colorado River, for the production of low-grade manganese, or for the development of nitrates, either for gunpowder or for fertilizer—and such works could not be financed, "it is the duty of the Federal Government at this time to help out the proposition and put it on its feet." He added: "I am not sympathetic generally with the idea of having the Government lend money to private enterprises because it is a hard thing to get it back. But I am very much in sympathy with the Government doing what it pleases with its own money, provided it knows where it is going and what it wants and how that money can be properly handled; and I am not afraid at all of the Government undertaking the development of water-power propositions, because we have had some experience with them in the Reclamation Service. The Salt River proposition which I have turned over to the water users is practically paying its own way now out of the power developed out of the Roosevelt dam. That was a venture at the time. All these propositions are gambles. That is one reason why a man who puts his money into a water-power project has got to have very real consideration. He is a developer, and every man who is a pioneer of any kind takes the risk, and for his risk he ought to be compensated."

Mr. Lane was asked some questions as to whether it will be possible for water-power plants to be built in time to be of service before the war is over. Very close attention was paid to the answer of the Cabinet officer on this point because men in public life in Washington have not recently been hazarding guesses as to the length of time which the struggle will continue. He said: "I have no expectation that this war will be over before water-power projects such as many that we know of can be developed. I think you have got to look at that thing with a long range."

Why I Buy Liberty Bonds

By George W. Munro

Assistant Professor Mechanical Engineering, Purdue University

Last spring twenty students of my class responded to the call of the nation and joined the colors, and this response was prompt, spirited and enthusiastic. Some of these boys are already on the fighting front and a few weeks will see them all at the grim business. These twenty men who have left my classroom for a place on the very lips of the bloody jaws of hell represent me in a very personal way, and I expect great things of them. I expect them to be brave with a courage which knows no faltering; I expect them to be chivalrous before an enemy wholly savage; and I expect them to reflect honor on my nation, my state and my university in all their dealings with men and women, friend and foe alike.

Of me they have a right to expect in return that I will not send them into a strange land to die of want and neglect. From me to them must flow a never-ending stream of food, of shelter, of clothes, of arms and munitions, of hospital supplies, of encouragement and good cheer. I must provide ships for their passage and provisioning, convoy for their safe conduct, aircraft for their battle eyes; and all the things which are necessary for their well-being, without limit or stinting. It is evident that I cannot serve these men directly but must use the agencies provided. I must support the Y. M. C. A., the Salvation Army, the Red Cross. I must pay cheerfully and gladly such war taxes as come within my reach and must buy Liberty Bonds and War Saving Stamps to the limit. Only so can I meet the reasonable expectations of those who have gone forth from my classroom to the edge of the abyss.

We are loud in our praise of James Watt for what he accomplished, but it is doubtful whether Watt would be as proud of his successors who are throwing away steam in the form of exhaust that is as good as some he used initially.

Why we should Buy Liberty Bonds

One year ago President Wilson said: "We will not choose the path of submission." Buy Liberty Bonds and show that you agree with him.

Germany has announced her eighth tyranny loan. We have offered our Third Liberty Loan. Can we allow ourselves to be outdone by Germany?

"When innocent blood from the four corners of the world cries out for justice," what will your answer be? Speak through the Third Liberty Loan.

Time enough to beat the sword into plowshares after the Kaiser is beaten into submission. The Third Liberty Loan is an effective weapon against him.

That man in khaki, to whom you wished "best luck," wants you to buy Liberty Bonds and show that you meant what you said.

If you don't believe in the premature peace that the pacifists demand, if you don't want to see the United States "Russianized," buy Liberty Bonds.

The time to talk peace is when the Germans lay down their arms. Just now, let your money talk in terms of Liberty Bonds.

Our Allies keep on supporting their war loans; Americans cannot afford to hang back in this Third Liberty Loan, when most of the civilized world is united against Germany.

You buy Liberty Bonds because you believe with every American in backing this war to the last dollar, the last soldier, the last ounce of energy.

Uncle Sam is offering you one kind of bonds, and the Kaiser another. The Kaiser's don't fit Americans of the breed of Washington, Lincoln and Wilson.

You owe a debt of freedom to America. Buy a Liberty Bond and help pay your debt.

Buy Liberty Bonds because they help to arm, outfit and feed the soldiers and sailors who are fighting democracy's battle under your flag.

Buy Liberty Bonds because they give you a chance to enter the richest partnership in the world, the United States of America.

Buy Liberty Bonds because the man behind the gun is doing his all and you want to do yours. He cannot fight long without your help.

The campaign for the Third Liberty Loan is a spring drive in which every American is summoned over the top. And let us all be shock troops.

Translate your good intentions into Liberty Bonds. Russia today is paved with good intentions—for the Germans to walk upon.

Our boys in France are as anxious as the Germans to know whether the Third Liberty Loan has been oversubscribed. Which will you disappoint?

You must buy a Liberty Bond to preserve your self-respect, to still your conscience and to prove your patriotism.

Purchasing a Liberty Bond will mean helping insure these United States against depredatory powers for ages to come.

Each of us should buy Liberty Bonds to assume at least part of the individual responsibility which the war imposes on the nation as a whole.

Unless we lend to the Government voluntarily by investing in Liberty Bonds, the Government will be forced to conscript our wealth.

Because those who have enlisted set an example of sacrifice, knowing that Liberty would be won by the small sacrifice made by those who remained behind.

Because by buying Liberty Bonds you are helping yourself and your country.

The American Citizen Should Buy Liberty Bonds Because they are for the Purpose of Defending His Country and His Home

Editorials

Daylight Saving the Year Around

THE Calder Daylight Saving Bill that provides for changing the working hours throughout the United States has been signed by the President and is now in force and will so continue until October 27 of this year, when the clocks will be set as they were before the change. It would seem that the idea might be carried still farther and the law so amended as to become effective throughout the year.

There are several features favorable to this change of working hours which would affect the home, the factory, the office and also electric-light plants. During the summer the saving in the home would center around the evening illumination, an hour's less lighting being required each day. During the winter months lights would be used both morning and evening, but the extra hour's lighting during the morning would be more than offset by the greater number of lights that would be shut off an hour earlier at night.

In the office buildings, in the larger cities at least, opening for business one hour earlier in the morning would not require the burning of lights and would save an hour's lighting in the late afternoon during the winter months. The lighting period in the factory would be shortened to some extent, depending upon the natural light conditions. During the period when the days are the shortest, the morning and evening lighting load would about balance, but during the early and late winter months the change of working hours would result in a saving of light.

These savings of light would result in a cash gain to the user, but to the electric-light companies it would mean a loss in revenue. On the other hand, such a loss would be beneficial in that the power load for the day and the evening lighting load would not overlap. Furthermore, it would not be necessary to maintain expensive equipment to carry the peak loads, as it is now. With a more even load on the stations, the boilers that are now held in reserve with banked fires in order to carry the peak loads caused by the lapping of the power and lighting demand would not be required.

Just what such a daylight-saving plan would amount to in coal saved by the power plant and to the consumer of electricity is shown by the statement of Samuel Insull, chairman of the Illinois State Council of Defense and president of the Commonwealth Edison Company of Chicago, which is to the effect that the enactment of an all year's daylight-saving law would save the electric industries of Chicago alone about fifteen thousand tons of coal per year and about two hundred and thirty thousand tons of coal for the entire country; and then it would save the electricity consumers in Chicago about three hundred and sixty-five thousand dollars and for the country seven million and a half dollars per year, which, by the way, would be the loss to the electric companies in revenue. This loss, however, would be largely offset by an improved load factor because of the reduction of winter peaks, and in many instances it would mean real economy in operation as well as a saving to the country as a whole.

Invest To Destroy Autocracy

THERE are two kinds of power. The first is the kind that is developed from the latent heat of coal or the self-perpetuating source of energy of waterfalls. The second is what is being temporarily exerted by Germany today—man power gone mad.

The former is the mainstay of all industry; the climax of man's intelligence. Through it vast distances have been opened for transportation, vast enterprises carried out to a successful end. Indeed, it is safe to say that the wheels of all industry would never have rolled in the wealth they do today if energy had not turned them into proper channels. With the wheels of industry yet unborn, the whole fabric of our every-day existence would be still an impossible dream. Your work, then, is the work of progress, development and the conquest of man over the uncurbed forces of nature.

The second phase of power has no part in the progress of civilization. Its presence is intolerable. By the power gained through ruthless savagery, Germany has conquered a large part of the unfortunates who have been unable to escape. Her power is the mad frenzy of a beast drunk with the blood of her helpless victims. It is well that that kind of power lost its place among mankind when civilization first made itself felt.

Those of us who are not in the army can stand together in helping to put down this uncontrolled and autocratic power, by subscribing to the Third Liberty Loan. Save for it; every cent you invest in Liberty Bonds goes toward helping to destroy the power of the beast of Europe, that power which is striving to destroy all that every true American holds dear.

Government Control of Water Powers

THE article "Government Control of Water Powers and Electrical Distribution Abroad," in this issue, deals with a question that demands the close attention of those interested in central-station work and the development of the water powers in this country. The policies of governments in their attempts to deal with the production and distribution of electrical power have undergone frequent changes following the rapid development of the central-station industry. The progress made in the development of overland transmission and the great saving to be derived from centralized production have opened the way for a new development in power legislation which seems to lead in the direction of complete governmental control over all agencies of power production if not finally to national ownership.

It is interesting to see how the attainment of this end is approached in the different countries. In England the power engineers and those interested in power consumption have worked out an extensive scheme which will centralize power production in a comparatively few generating stations which will supply a territory now served by more than six hundred central stations. Prussia forces its central stations to fall in with its own policies by simply taking administrative action which will make it impossible for the existing enterprises to expand unless they do the will of the government; it has also entered the central-station business on its own account and now competes against the existing private and municipal enterprises, assisted by large generating stations conveniently situated. Finally, there is the example of New Zealand, where government ownership has been in successful operation for many years.

The importance of reserving the existing water-power resources of the country so that they may be used to the best interest of the nation is now generally realized throughout the world, and many laws have been passed regulating the use of waterfalls and other natural power sources. With increasing industrial activity it has become essential that this power should not be squandered and that it should be provided for all at the cheapest possible rate. This can be done by a better use of the existing natural resources and by centralization of the existing central stations. While the means to that end used in the different countries differ, it seems that the final outcome in each case will be identical.

So far there is no evidence that it is also contemplated to nationalize the means of distribution. On the contrary, opinion seems to be very largely in favor of continuing the existing organization, which has proved itself to be the most practicable for the purpose.

The development is one which certainly cannot be lost sight of in our own power industry. With the whole world striving today for a cheapening of power production, it is certain that similar action will have to be taken very soon in our own country.

Bonus for Boiler-Room Crews

THE world was never so aroused to the need of saving fuel, indeed never was so astounded by its wasteful use, as it is now. *Power* has watched with keen interest the effect of the great volume of publicity directed chiefly to firemen and engineers, pleading with them to save coal. The good this publicity has done is not the measure of fuel actually and immediately saved. This is yet to come. The great good comes through the channel in which, unwittingly, the manufacturer and manager have stood as obstructions. Of course there are many exceptions. But many of these men did not realize before the coal shortage how vital a factor is coal and how important it is to check its use in the power plant. Thousands of such men, who heretofore would not listen, or would listen unconvinced, to pleas of their engineers for instruments to gage power-plant performance or for equipment to better such performance, will give a willing ear from now on.

Begging firemen and engineers to save coal, appealing to their patriotism to do this, will do some measure of good. But to him who knows, there are limitations soon reached by such a course. In last week's issue, Haylett O'Neill, well known to *Power* readers, proposes a plan by which boiler-plant crews may receive bonuses for fuel saving effected by careful attention to operation and maintenance of boiler-room equipment. Here is something that gets the enthusiastic support of the crew just as soon as they understand what it is all about.

The author proposes paying a bonus only to the firemen, fire cleaners and boiler cleaners—that is, to those whose work it is to burn the coal economically and keep the boiler and furnace in the "pink" of condition physically. Assumably he includes the foremen when applied to large plants, and the engineer also in plants where he is responsible to the management for the condition and performance of the boiler plant.

The Daily Grind

THOUSANDS of men in thousands of power stations in the United States and, in fact, throughout the world are obliged to go through with the daily grind. One day is very much like the next, and it frequently gets to be an old story for some. The duties of the engineer and fireman are not always pleasant. There is a continual handling of coal, feeding of water, disposal of ashes, blowing down, cleaning, oiling, wiping, repairing, making of reports—all necessary and responsible work, but ofttimes dull and irksome. The boiler or engine room is no place for the mollycoddle. There are dirt, soot, scale, heat, poor ventilation, inadequate equipment--all enemies of the self-respecting operator. One is really tempted at times to ask himself the fruitless question, "What's the use?"

But there is another side to all this. If the work of any man in a power plant is uninteresting, it is his own fault. The very fact that there are enemies to conquer makes life interesting. Even the simplest duty is worthy of the best efforts and calls for the exertion of the greatest powers of the whole man. Many people, whatever their occupation, only live half a life. They fail to recognize their opportunities. They spend their energies bemoaning their fate or cursing their luck or wishing that they were born rich or good looking. What a waste of time! How much better would it be if they took an equal amount of pains to improve conditions. Nothing is so bad but that it can be made better, and the way to make it better is to think, talk, decide and do.

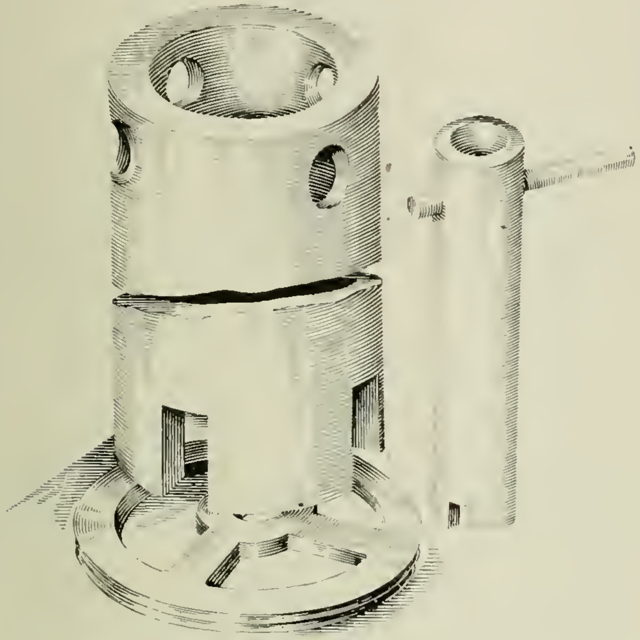
Cheerfulness is the best servant of any man. Some men about a plant are so disagreeable that they are actually shunned by their fellows. They are not only burdensome to themselves, but they are a pest. Whatever good they may wish to accomplish is already nullified by their very attitude.

We are said to be creatures of our environment, and to some extent this is doubtless true. Fortunately, however, it lies within our power to alter our environment. If you don't like your job, get out and secure one that you do like, but make sure first that it is the job, and not you, that is disagreeable. If the daily grind seems irksome, do your best to make it interesting. Do not be discouraged by setbacks. The best fighter is the man who cannot recognize failure—who does not know when he is licked.

Correspondence

Pump-Valve-Seat Wrench

A valve-seat wrench made of pipe with slots cut in the end to match the spider of the seat will prove effective and will serve in awkward places, such as depressed decks or where there are projecting studs.



PUMP-VALVE-SEAT WRENCH

It may be turned with a Stillson wrench or with a bar in holes drilled in the pipe.

I have taken seats out without injuring them where it took two men with a 6-ft. pipe on a 48-in. wrench to start them—the wrench being made as described of 3-in. extra-heavy pipe. The pipe should be the largest size that can be put into the valve to bring the force as near the point of resistance as possible.

San Francisco, Calif. **Arthur B. Saunders.**

Gas Engines of Former Times

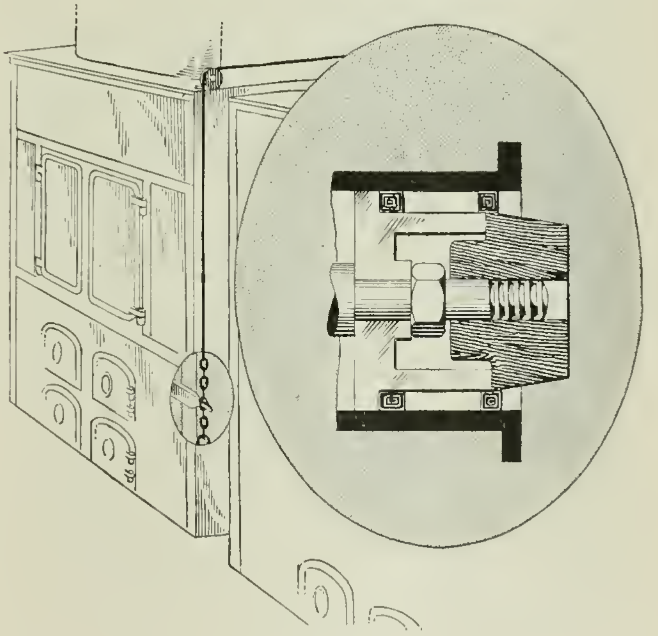
Referring to the letter, "Gas Engines of Former Times," on page 164 in the issue of Jan. 29, it may be interesting to *Power* readers to know more about a gas engine called the Automatic, which was manufactured at Oil City, Penn., about the date referred to. This engine had the following earmarks: The ones that I came in contact with were horizontal four-stroke-cycle with one rotary valve driven by a camshaft. This valve controlled the air inlet and also an exhaust. Ignition was obtained by the old-time hot tube, and the governor was of the throttling type, controlling the quantity of admission. The engine was nicely balanced, was almost noiseless and would run at a high rate of speed. Trouble, however, always developed in the rotary valve, cutting and causing loss of compression.

This made a bad job to repair, and I think that was what put the engine off the market. I have heard that some shops fitted poppet valves to these engines and got good service from them. It occurred to me that the writer of the letter referred to may have had one of these engines or that some other contributor might be able to give some interesting reminiscences in regard to it. **Lloyd R. Hoffman.**

Oil City, Penn.

Holding Damper in Position

A damper control can be put in in a cramped place if ¼-in. wire sash cord is used with "side pulleys" at necessary turns, and it will last indefinitely. I use a section of light chain down the boiler front, of a length equal to the travel of the damper lever, securing it over a hook at any desired damper opening—the chain serving also as an indicator of the damper position.



TWO SELF-EXPLANATORY SUGGESTIONS

For the relief of distressed worthy brothers whose patience and stock of profanity runs out when they try to pack the water end of a feed pump, especially when it is hot and valves leak, I would recommend the kind of device I use, for I can drive the packing into place as fast as a helper can cut it. It is a tapered wooden plug, the large end of which is the same size as the body of the piston, with a hole in its center of the same size as the projecting end of the plunger rod or the locknuts and deep enough for the plug to butt against the piston. The packing rings can be easily slipped over the small end and driven into place by this means. **Arthur B. Saunders.**

San Francisco, Calif.

Favors an Ash Inspector

The editorial on page 267 in the issue of Feb. 29, regarding appointing ash inspectors strikes me as being mighty good dope. Last winter at my home we burned eight tons of pea coal, not sifting any of the ashes. This winter, sifting them, we have not burned six tons yet, and we expect to use not more than six and one-half tons. If a ton and a half out of eight can be saved by sifting the ashes as we have done this season, I can easily imagine what a big saving can be made in the nation's coal pile by having an ash inspector or someone to take care of the ashes not sifted.

One large city in the East has considered the proposition of building an ash-sifting plant, and it was thought that enough coal could be obtained from the ashes gathered to run the city several months of the year. This estimate, I believe, is not far wrong, for in walking along the streets in the morning I have noticed that the contents of the ash boxes are nearly half coal.

Protection of Furnace Walls

In the Jan. 8 issue of *Power* appeared an interesting article on "Ventilated Side Walls." In hand-fired furnaces with natural draft it is highly desirable to eliminate abrasion from firing tools and clinkers. As pointed out in the previous article, perforations in side walls are of little effect in furnaces of this type. We have used with success side grates of special design, not only to overcome the clinker troubles, but also to improve combustion conditions when the coal contains a considerable amount of volatile.

Fig. 1 shows the side grate in position. By correctly proportioning the free area and height of these grates, the quantity of air entering over the top of the fuel bed is practically self-regulating. After a new charge the fuel bed is thicker and offers greater resistance to the air than after the fuel is partly consumed. The air will seek the path of least resistance and, when the new charge of fuel is introduced, will pass through the openings of the side grates at a greater velocity when it is needed above the fuel bed to consume the volatiles. The greater velocity will also help to effect a better mixture of air and combustible gases. The lower resistance of the fuel bed during the later part of the period decreases the inrush of secondary air through the side grates. This difference seems comparatively small, but has proved its effectiveness in practice. Care must be taken to supply these side grates with proper cooling surface. The proportioning of the cooling ribs and the air openings spell success or failure. In the furnace shown in Fig. 1 there is also provided a flame port formed by an arch over the bridge-wall, as a means of enhancing the mixture of the furnace gases and air. Openings are provided to hinder the formation of gas pockets.

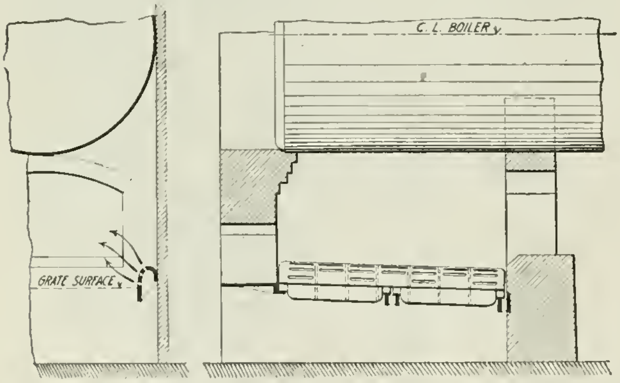

FIG. 1. PERFORATED SIDE GRATE TO ADMIT AIR, OVER FURNACE

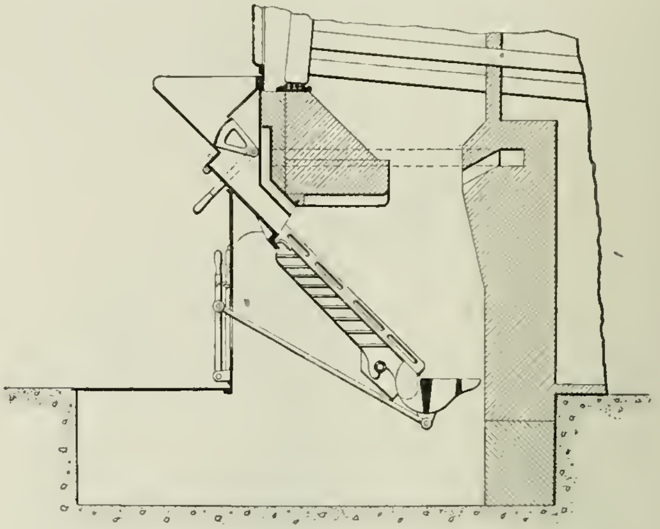

FIG. 2. SIDE GRATE FOR SLOPING FURNACE

Fig. 2 shows a successful side-grate installation for a sloping-grate furnace. In this case the construction of the side grates is more simple. The only delicate point is the provision of sufficient cooling surface to prohibit excessive temperatures and premature destruction of grates.

Joseph Goder,
Chicago, Ill. Boiler Efficiency Engineer.

Using a Pitot Tube

In the issue of Feb. 5, page 195, Mr. Brye gives suggestions concerning the use of a pitot tube. It is not my purpose to discuss the construction of the tube as shown; although one might criticize some features of it, there are other features that are admirable. I wish to call attention only to the difficulties connected with his plan of determining the average velocity in the pipe. In the first place it is somewhat troublesome in practical work to divide the cross-section of the pipe into concentric areas that are equal; then, after having thus divided the cross-section, it is exceedingly hard to locate the tube at exactly the right position in each of these equal concentric areas. In the third place there would be a comparatively large distance near the middle of the pipe in which but one velocity reading would be taken. Under certain conditions it would be very desirable to have more readings from this central area.

I would suggest that it is much easier to take the velocity readings at definite distances (which may be equal or unequal) along the diameter of the pipe. In determining the average velocity it would be necessary to calculate the area in cross-section of the water traveling at any of the obtained velocities, then giving proper weight to each of the calculated velocities, the average velocity is obtained.

Operating Induction Motors at Reduced Frequency

A mill operator requested that the motor drives in his plant be investigated for the purpose of reducing the speed of practically all the machinery. It was found that there were about thirty motors in the mill, most of them direct-connected to the machines they were driving and all operated from the mill's electric plant. The trouble, it appeared, had come about by the mill designer's errors in calculating the motor speeds, and the machinery was considerably overspeeded, so much so in fact, that the quality of the product was seriously impaired.

The power plant was found to be operating at the proper frequency and voltage and was in excellent condition. As an experiment the governor on the engine was changed to reduce the frequency 10 per cent., or from 60 to 54 cycles. The mill machinery operated properly at this speed with the exception of one or two belted motors on which the pulleys could be changed easily, so it was determined to continue the operation at the reduced frequency. However, when heavy loads came on, it was found that the voltage dropped seriously although it was controlled by a regulator.

After some testing it was found that the exciter, which was belted to the alternator, was running too slow to generate sufficient voltage to properly excite the alternator's fields. The pulley was changed so as to increase the speed of the exciter slightly above normal, and after this change no further trouble was encountered, and the plant and mill have been operating continuously since.

During the test after the governor had been adjusted, attention was given to the electrical operating characteristics of the equipment, but the instrument changes were slight except on the frequency meter. The kilowatt output was slightly decreased and so was the power factor; the amperage increased slightly, and the voltage remained constant. D. R. SHEARER.

Johnson City, Tenn.

Different Rate of Scale Formation in Boilers

The letter by Mr. Bennett in the issue of Feb. 12, page 231, regarding the different amounts of scale to be found in boilers interested me very much. At one of our boiler plants we have six large B. & W. boilers, all working under the same pressure and using the same feed water, but one-half of each boiler will always have more scale than the other half. The difference is so great that, when cleaning, three or four tubes on the easy side can be bored in the time it takes to bore one on the hard side.

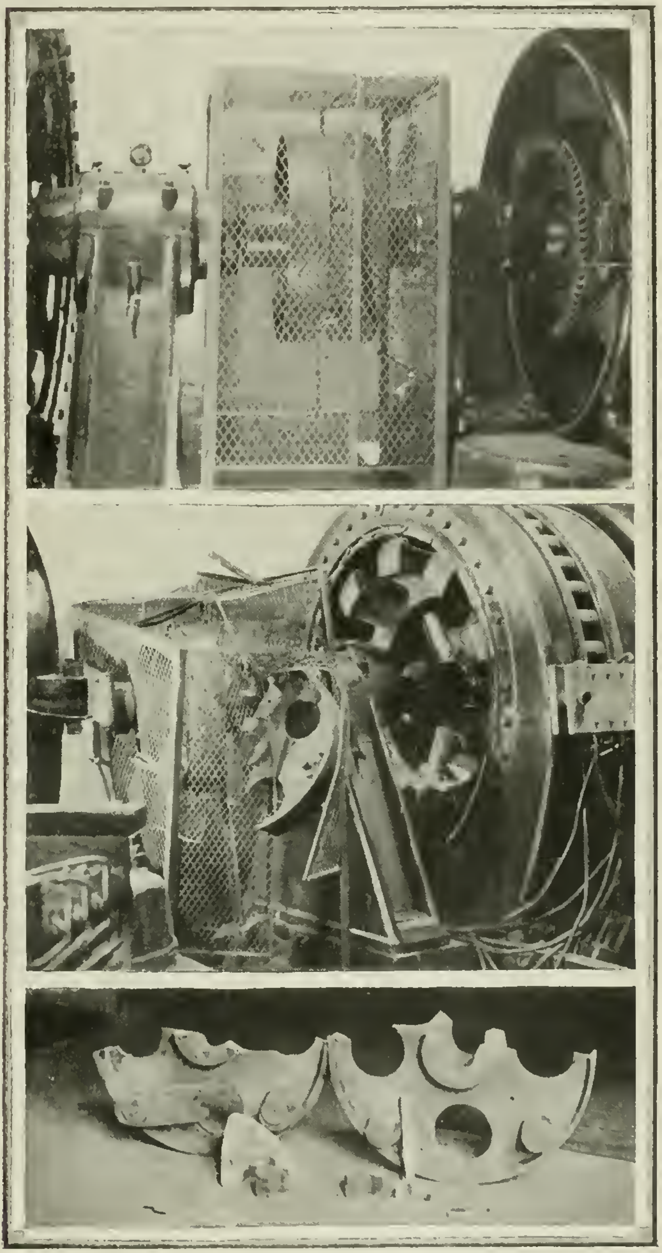
These boilers have been in use for many years, and this condition has always been the same. During the time they have been in operation, the feed water has been taken from three different sources; still the same condition exists. The soot is removed by inserting a blowpipe at one side through openings provided for this purpose, and this is the side that is always found with the greatest amount of hard scale. Whether this is what makes more and harder scale on that side than on the side where no blowing is done, I am unable to say. THOMAS J. PASCOE,

Norway, Mich. Oliver Iron Mining Co.

Safety Guard Prevents Injury

The upper photograph shows a wire-mesh guard around a 30-in. (diameter) shaft coupling on a motor-generator set operating at 360 r.p.m., the middle one shows the broken coupling with all the pieces retained within the guard or directly underneath on the floor, and the lower one shows the broken coupling after removal. This accident happened in one of the substations in the San Francisco District on Dec. 27, 1917. I am sending these photographs, thinking that they may be of interest to *Power* readers, bringing out the effectiveness of this guard not only as a protection from contact with revolving parts, but also from flying parts in case of breakage. V. R. HUGHES,

San Francisco, Calif. Safety Inspector.



CONFIDENCE IN GUARD JUSTIFIED

Telescopic-Oiler Discussion*

The discussion of telescopic oilers recently appearing in *Power* has brought out useful points. As H. Hamkens pointed out at the beginning of the discussion, the main disadvantages of most telescopics, especially the older ones, are too many parts, leakage of oil, tendency to irregular feeding, too rapid wear. He might have added, the almost general difficulty of nonalignment after repairs and cleaning.

It is true that the older telescopics were somewhat complicated and, what with numerous springs, locknuts, washers, etc., they were hard to keep in repair and in good working order. But the design has gradually been simplified and improved until today oilers can be procured which are apparently as simple as it is possible to make them.

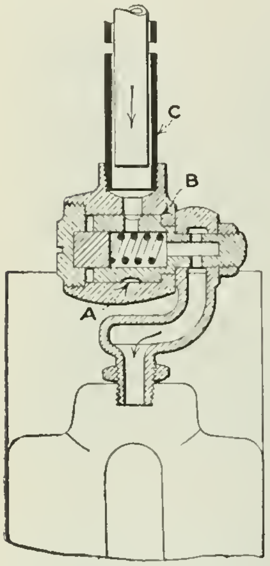


FIG. 1. MR. FENNO'S ARRANGEMENT

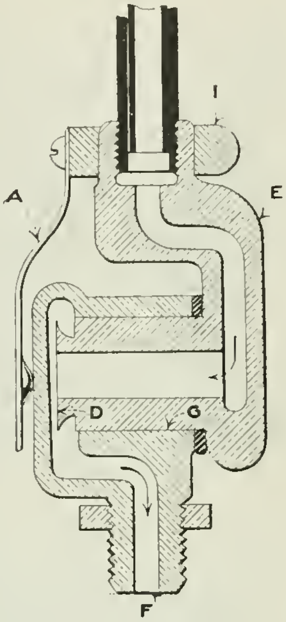

FIG. 2. MR. NUGENT'S DESIGN

As Mr. Fenno pointed out in his article in the July 17, 1917, issue, the tendency to pumping and irregular feeding can be overcome simply by providing suitable clearance between the inner and outer telescopic tubes.

The rapid wear of the tubes noticed by Mr. Hamkens in some instances, is the result of their binding upon each other due to imperfect alignment either when installed or after reassembling. This can be avoided by due care when installing and, with some telescopics, extreme care when reassembling. It all depends upon the type of joint employed.

By employing the special design of true male and female joint shown in the illustration, all wear due to imperfect alignment, except that due to poor installation, is completely avoided, because no threading is even disturbed. Also, because this joint permits of gravity feed, the pumping tendency is practically, and leakage completely, eliminated.

With the arrangement shown by Mr. Fenno and illustrated in Fig. 1, the oil accumulated at the bottom of the outer element as at *A*. In other words, the flow of oil is against the direction of the joint instead of with it. Hence, the fiber packing *B* is always in contact with the oil and subject to deterioration and leakage.

In most of the older designs the joint could not be taken apart without first unscrewing the telescopic pipe *C*. This meant that with any irregular alignment whatsoever in the initial assembling, the pipe would have to be screwed up to exactly its original position when reassembled, or extreme wear was sure to ensue.

With the type of joint shown in Fig. 2, both wear and leakage are practically overcome. The overhanging lip *D* drops the oil from the movable element *E* directly into the hollow of the fixed element *F*, and hence, unless the oil is fed in a flood greater than the latter can conduct it to the pin, the joint *G* remains leakless.

The joint is taken apart by sliding off the spring clip *A*, which is attached to the loose collar *I*. The movable element *E* then slides out of the fixed element *F*. As the construction at the top of the telescopic is similar, the telescoping pipes may both be removed without detaching them from their parts of the joints. Hence, they can always be replaced in alignment. As no nuts or screws are used in putting the joints together, they may be taken apart for cleaning or inspection while the engine is running unless the speed is uncomfortably high.

Chicago, Ill. WILLIAM W. NUGENT.

Testing Field-Pole Polarity.

In putting into service a new generator or motor or one that has been repaired, it frequently requires considerable testing to find whether the field poles have correct polarity; that is, alternate north and south poles. The figure shows a simple way of determining the correct polarity. First, excite the field coils and then take two wire nails and placing their points on adjacent polepieces, then bring their heads close together, as in the figure; if they attract, the poles are the correct polarity, since unlike poles attract. On the other hand, if the nails repel each other, the polarity of the polepieces is wrong and must be corrected by interchanging the lead on one field coil. In this way it requires only a few minutes to examine the whole machine

New York City. D. R. HIBBS.

Inquiries of General Interest

Relative Dimensions of Extra-Heavy and Standard Pipe—Is the difference in thickness of extra-strong pipe and tubing from that of commercial standard pipe and tubing in their variation of inside or outside diameter? J. L.

The greater thickness of the extra-heavy pipe and tubing is provided by having smaller actual inside diameter than the same nominal size of standard pipe, the external diameter being made the same so as to be suitable for standard-pipe screw threading.

Pressure Equivalent to Zero Inches Vacuum—When a vacuum gage shows 0 inches of vacuum, what is the pressure? R. A. S.

"An inch of vacuum" signifies one inch of mercury column pressure less than the pressure exerted by the atmosphere. Hence the pressure for zero inches of vacuum would be the same as zero gage, or the pressure of the atmosphere above a perfect vacuum, which, unless otherwise qualified, is assumed to be equivalent to the intensity of pressure exerted by a column of mercury 30 in. high when at the temperature of 62 deg. F., or an absolute pressure of 14.7 lb. per square inch.

Length of Open Belt—What would be the length of an open belt to go around pulleys respectively 8 ft. and 4 ft. 6 in. diameter and 24 ft. center to center? H. C. B.

The approximate formula for obtaining the required length is

$$L = 2C + \pi\left(\frac{D + d}{2}\right) + \frac{(D - d)^2}{4C}$$

where

L = Length of open belt;
C = Distance center to center of pulleys;
D = Diameter of larger pulley;
d = Diameter of smaller pulley.

By substituting,

$$L = (2 \times 24) + 3.1416\left(\frac{8 + 4.5}{2}\right) + \frac{(8 - 4.5)^2}{4 \times 24} = 67.76$$

or practically 67 ft. 9 in.

Latest Cutoff of Single-Eccentric Corliss Engine—In ordinary operation of a single-eccentric Corliss engine, why cannot cutoff take place later than one-half stroke? F. E. G.

Each exhaust valve must be opened and closed by a forward and backward motion of the wristplate to one side of its central position during one stroke, and as the operation must be accomplished during 180 deg. of the revolution of the shaft, the motion of the wristplate to one side of the central position must occur during 90 deg. of the revolution, or about one-half of the stroke of the piston. As a steam valve must not open until the exhaust of the same end has closed, and cutoff must be effected by the cutoff cam while the steam valve is carried by the wristplate in the initial direction for opening, and before the wristplate begins to return toward the central position, cutoff cannot occur later than 90 deg. of revolution of the eccentric, from the time the wristplate is in its central position or about one-half stroke of the piston.

Setting Common D-Slide Valve—What is the method of setting the valve of an ordinary D-slide-valve engine? A. N.

Uncover the valve chest and adjust the length of the valve rod so each end of the valve will overtravel the steam ports the same amount, either from turning the engine over with the eccentric fastened to the shaft or from turning the loosened eccentric all the way around the shaft. Then put the engine on a center and set the eccentric at such a position on the shaft that, with forward direction of rotation of the shaft, the end of the valve would begin to uncover the steam port on the end of the cylinder that contains the piston, or set the eccentric forward far enough to obtain the desired amount of lead opening. The engine should then be turned over on the other center to ascertain whether the same amount of lead has been obtained for the other end of the valve. If not, take out one-half of the difference by readjustment of the length of the valve rod. If more lead is desired for both ends, it can be obtained by shifting the eccentric forward on the shaft or less lead by shifting it backward.

Whole-Coil and Half-Coil Windings—What is the difference between a whole-coil and a half-coil winding? A. R.

In concentrated winding sometimes used on alternating-current machinery, a whole-coil winding is one in which there is one complete turn or coil per phase per pole, as in Fig. 1. A half-coil winding is one which has only one complete turn or coil per phase per pair of poles, as in Fig. 2.

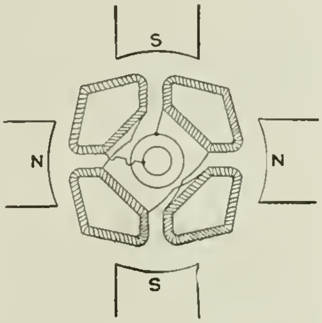

FIG. 1. WHOLE-COIL WINDING

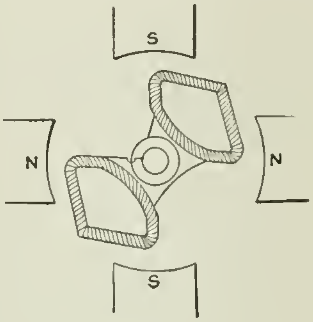

FIG. 2. HALF-COIL WINDING

Advantage of Inclosing Heating Returns—When steam at 105-lb. gage is supplied to drying coils in which the pressure is maintained at 5 lb. gage, with the condensate discharged against atmospheric pressure and returned to the boiler at 180 deg. F., what percentage of saving would be effected by returning the condensate under 5 lb. pressure? H. L. W.

If the coils discharge direct to the atmosphere without being trapped, no comparison of economy can be made without knowing the percentage of steam thus wasted. If the present discharge consists only of condensate that is formed in the coils and returned to the boiler at 180 deg. F., then as one pound of steam at 105-lb. gage or 120 absolute contains 1189.6 B.t.u. above 32 deg. F., for reconversion into steam each pound of the return water must receive from the boiler 1189.6 − (180 − 32) = 1041.6 B.t.u. The relatively small amount of heat that would be saved by reason of supplying the boiler feeder with water at 5 lb. higher pressure can be neglected. The principal consideration would be the temperature of the returns as received by the boiler. The temperature of the condensate when formed in the coils would be the same as the temperature of dry saturated steam at 5 lb. gage, namely, about 228 deg. F., but there would necessarily be some reduction of this temperature in handling the returns. Assuming that the actual temperature of the condensate as returned to the boiler is 220 deg. F., each pound of steam generated would require 220 − 180 = 40 B.t.u. less than with the feed temperature at 180 deg. F. and the saving would be 40 × 100 ÷ 1041.6 = 3.84 per cent., practically 1 per cent. for each 10 deg. temperature of the feed in excess of 180 deg. F.

Central or Independent Power Service[*]

BY FREDERICK B. KENNEY[†]

A survey of the reasons for the development of the central electric light and power industry. Discussion of the paper is given.

THE term "central station" has today lost, through popular application to central stations for the distribution of electric light and power, its inclusiveness of all central sources of supply of a commodity or service essential to the well being of a community. In the widest significance of the term can be included all central sources of supply which time and economic conditions have developed through a knowledge and realization that certain essentials can be manufactured, developed or supplied to best advantage on a coöperative or community-of-interest basis.

The coöperative store is perhaps the first central station worthy of note, followed by the metropolitan water system, the central gas plant, the central electric light and power plant, and finally by the utilities for the transportation of ourselves or our goods, for either short or long distances.

THE CENTRAL STATION A NATURAL DEVELOPMENT

The central station is the natural development of such realization, for while each family in a community could today maintain a private well for its water needs, the absurdity of attempting this for any reason is apparent. Again, the family which once was content to make its own tallow dips could today maintain its own little acetylene-gas plant, but where such a plant can be found within the territory supplied with illuminating gas from a central gas plant, common sense is not one of the factors responsible for its maintenance. The same argument can be applied to our transportation needs, for were we as individuals compelled to rely today upon our physical ability to fill them, we would indeed be sadly limited in our travels and in all supplies not available in our immediate vicinity.

Centralization is decidedly apparent in manufacturing, for the origin of all manufactured articles can be traced to the individual home until demand and economic needs developed the factory.

To confine ourselves to the popular interpretation of the term "central station" and to attempt to compare its value with that of the "isolated plant," a knowledge of the history and development, with a full realization of the field occupied by each, is essential. Since light, heat and power are the products of each, a slight review of the present and past needs is not out of place.

In the Eighteenth Century Newcomen produced the first steam engine which seemed commercially practicable. A number of these engines were installed for pumping purposes in the mines of England, but not until late in the same century was the steam engine, as we recognize it today, placed on the market by Watt and his associates.

It is of interest to note that at this period illuminating gas was developed from coal by a Scotchman named Murdoch and utilized in the shop of Boulton and Watt in Birmingham, England. Shortly following, London Bridge was illuminated with coal gas, and for the distribution of this new illuminant was born the central-station idea coincident with the prime mover which is today the backbone of the isolated plant.

The steam engine as improved by Watt found a receptive field in various industrial plants, notably in the cotton industry, which at this time in England was rapidly undergoing radical changes in mechanical equipment. The beam type was accepted as standard until the middle of the Nineteenth Century, at which time the horizontal type came into favor, followed shortly by the Corliss type, which with certain refinements, is standard today.

Though engines of many types and arrangements of valve gear appeared from time to time, the reign of the heavy slow-speed engine was undisputed until 1879, when the perfection of the incandescent lamp by Edison ushered in a new phase of the light and power problem and gave birth to the electric central station as it is popularly known. The need of high-speed engines to drive the new generators devised by Edison was first met with an engine designed by Edison himself, followed by engines of other manufacturers quick to realize the possibilities of the new incandescent lamp. Designers of the steam turbine renewed their efforts to perfect their machines.

Late in 1882 was established in Appleton, Wis., the first central electric-light station for the distribution of electricity. Curiously enough this little station of 250 ten-candlepower lamp capacity was a hydro-electric plant, the generator being driven by a waterwheel. This seems almost prophetic of what to many seems to be the ultimate of economic efficiency with such apparatus as is now available.

The following year saw the establishment of central stations in many of the larger cities, and the demand throughout the country for such service for a while exceeded the ability of the manufacturers to supply the necessary apparatus and lamps.

The growth of the central station from that time has been rapid and is perhaps best reflected in such figures as are available from the Federal Census since that date as follows:

Commercial Only	1902	1907	1912
Central stations	2,805	3,462	3,650
Kilowatt capacity	1,099,000	2,500,000	4,766,000

Figures for 1917 are not yet available, but it is interesting to note that while the total number of stations in 1912 had increased by less than 6 per cent. over the total of 1907, the total capacity had increased by over 90 per cent. This rate of increase has probably been maintained during the last five years, and it is reasonable to suppose the present total capacity approaches very closely 9,000,000 kilowatts.

Development of the electric motor, together with consolidations, reorganizations and centralization of management, soon put the central station upon a solid foundation and direct competition with the isolated plant was the inevitable result. With the large field for power opened to the central station by the electric motor, a greater output over which to spread overhead charges resulted. With increased demands, larger units followed, with higher efficiencies and lower operating costs. Some idea of the net results relative to steam prime movers and motors operated with purchased current in industrial plants can be obtained from the census figure for the years 1899 and 1909 as follows:

Capacity In	1899	1909
Steam generated power, horsepower	8,200,000	14,200,000
Purchased electric, horsepower	182,500	1,750,000
Total of both sources	8,382,500	15,950,000

While the total capacity in steam power had increased by 75 per cent., the total purchased power had increased by 960 per cent., and whereas the purchased power in 1899 was a trifle in excess of 2 per cent. of the total, in 1909 it had become in excess of 11 per cent. of the total. Figures for the last eight years will no doubt prove equally as creditable to the central station.

Meanwhile the sponsors for the isolated plant have not been idle and, profiting by the experiences of the central station, have disposed of obsolete equipment, eliminated wasteful methods of transmission, installed modern and efficient equipment and taken measures to obtain the maximum economies possible. For these the day of surrender to central-station service is deferred, but not entirely eliminated. For the plants that have not profited by the experiences of the central station and have neglected to im-

[†] Mechanical Engineer, Blackstone Valley Gas and Electric Co., Pawtucket, R. I.

prove their conditions, the handwriting on the wall is clear. There always will be exceptions to this probability, dependent upon peculiar and local conditions.

Probably no better method of outlining the truth of this can be employed than to apply the arguments for and against central-station service to a typical plant familiar to the writer. The plant in mind furnishes light, heat and power for a cotton mill of the usual type, spinning its own yarn and utilizing it all in the weaving of plain cotton fabrics.

The engine plant consists of two old Corliss cross-compound engines operating condensing, one of approximately 1200 hp. rating and the other of approximately 600 hp. rating and both about thirty years of age. Transmission is mechanical throughout. Steam is furnished from a battery of water-tube boilers. Heating is done with live steam. A mixture of about one part bituminous to three parts buckwheat coal is burned. The average load carried approximates 1400 i.hp. The actual operating costs for the year 1912 were $25,000, which includes no overhead charges, with slight repair or maintenance charges. The engineer in charge is a most capable man and is obtaining results that could hardly be bettered with any apparatus that could be installed. The physical conditions in transmission are, however, extremely bad, and fully 40 per cent. of the power generated is dissipated in friction. It is estimated that 900 hp. in motors would handle this mill to much better advantage than it is being handled at present. With 2,000,000 kw.-hr. per year at 1c. per kw.-hr., the cost of current to this mill would be $20,000; overhead charges on motor equipment (based on 1912 figures), $1500; heating and all other charges, $6500; total, $28,000; apparent balance in favor of the isolated plant, $3000 yearly.

Eventually, this plant for physical reasons must be replaced. At such time overhead charges must be considered, and assuming the installation of a 1000-kw. plant with a minimum cost of $100,000, the immediate yearly burden approaches $12,000. Add to this the item of $1500 burden on motors and $6500 for heating and incidental operation, a total of $20,000 is chargeable to the power plant before the generation of a single kilowatt. Since the central-station price for the service is estimated at $28,000, $8000 is available for the generation of 2,000,000 kw.-hr., necessitating a generation figure of $0.004 per kw.-hr. Assuming this new plant operated at an economy of 2.5 lb. of coal per kw.-hr., with coal at $3.50 per ton as in 1912, the resultant coal charge becomes $7700.

Similar illustrations could be furnished, but probably this is sufficient to illustrate the facts where the average industrial plant is concerned. In considering hotels, bleacheries and plants where the utmost use of exhaust steam can be made, different conditions are encountered which make it more difficult for the central station to justify abolishing the isolated plant, but since the same is being done daily, it would seem that such action in many cases can be justified. However, in each of such cases, the proper course can be determined only by individual analysis. Aside from all the considerations outlined, the question of coal supply is important. Reverting to the case of the mill outlined, the total coal required for power purposes in this mill was in excess of 4000 tons yearly. To furnish 2,000,000 kw.-hr. yearly to this plant the coal required by the central station would approximate 2000 tons. The application of this ratio to the requirements of the many isolated plants throughout the country furnishes abundant food for thought in view of the present coal situation.

In conclusion, it must be apparent that in the mind of the writer the isolated plant, except for isolated cases where geographical or peculiarly local conditions prove the exception to the rule, is surely bound toward central-station service. The day for a large number of plants may be long deferred, but eventually economic efficiency will prevail.

Discussion

Warren B. Lewis, consulting engineer, Providence, R. I.: If, before I finish, I appear to be harshly critical of some of the features of Mr. Kenney's very excellent paper, it will not be by reason of antagonism to either the speaker or his subject, but will arise from an attempt to emphasize the weakness of some of the arguments advanced for and against central-station service.

Mr. Kenney says that this is an era of centralization. This is the strongest argument that he uses, and I think that he might have carried it farther by saying that there is no more reason why manufacturers should generate power than that they should enter into the business of manufacturing the raw materials that they use. Up to within a few years ago it was necessary that they should manufacture their own power because they could not get it any other way; and I venture to say that most of them have always considered it as one of the most irritating departments of their business and looked upon it as a "necessary evil." Now that they can purchase power delivered f.o.b. their factory, there would seem to be little excuse for considering any other method. Power bears no relation to manufactured product as far as being a constituent element; and specialization is as logical in the manufacture of power as it is in the manufacture of machinery or textiles.

Again, there is little justification in investing one's money in power plants as a mere department of one's regular business on the basis of a net return of 5 or 6 per cent. (which is the rate usually charged into the costs), when the same amount of money would probably earn from two to three times that amount when invested in the business itself. However, while these are perfectly good arguments, they are very general ones; and, after all, the question is not the central station vs. the isolated plant, but it is the central station vs. some particular isolated plant.

Mr. Kenney, for instance, states that for one to maintain a private well for his water needs would be an absurdity from any viewpoint. Private wells are quite general in the midst of large cities, and the matter is purely one of the amount of water used and the cost of pumping it. It certainly would be an absurdity for each individual family to run its own water-works as suggested, but it is not an absurdity for an individual who needs large quantities of water at a fairly uniform rate of flow. So with other facilities. Expediency of individual effort is determined largely by the particular characteristics of the case in question.

Mr. Kenney goes on to give the history of the development of steam engines and the electric-lighting industry, arriving ultimately at the conclusion that the huge units made possible through the centralization of the power business have brought about efficiencies that could not be attained by the individual producer. This is true when referred to small users, but is not always true in the case of the larger users. Furthermore, the centralization of the industry has added expenses of distribution, management, cost accounting, investigation, research, etc., which makes the actual cost of power at the point of generation a comparatively small percentage of the whole. These expenses, not being incidental to the cost of the power produced by the individual, are in many cases a handicap.

If we are to indulge in general arguments, it is safe to say that the cost per unit of power installed must, in the case of the central station, be as great, if not greater than for the case of an isolated plant of considerable size, when one takes into consideration the investment in auxiliary equipment, distributing systems, real estate, etc. The central station must earn fixed charges, as well as the isolated plant; and if there is any advantage in this respect it is that the central station can figure lower fixed charges than can the isolated plant.

From the viewpoint of running costs, I doubt whether the pounds of coal consumed per kilowatt-hour are much, if any, less in stations of from 25,000 to 30,000 kw. than in many textile plants of a thousand kilowatts. Here again Mr. Kenney might have emphasized the fact that the central stations have a corps of technical experts who are constantly studying problems of economy where the usual isolated plant does not, and that the central station will maintain its efficiency for a much longer time than will the isolated plant; and therefore, the figures for the latter, previous to its installation, may not be of much weight five years after.

Mr. Kenney goes on to cite the case of a cotton mill. I find the figures rather general, which always leaves one in doubt as to whether any conclusions can be drawn after all. He admits at the start that the plant had a most inefficient drive and was wasting 40 per cent. of the power generated. Whether this mill continued to make its own power or purchased it, it is evident that it would have to spend considerable money not only to install motors but to rearrange entirely its shafting, belting, etc., to reduce the load from 1400 to 900 hp.; and the expense would be put upon the mill in any event. The real comparison would then come as to whether power could be purchased at the switchboard at the price at which it could be made in the isolated plant; and it would not be necessary to take into consideration overhead charges on motor equipment, shafting, etc., nor on heating or steam used for processes.

He quotes a price of one cent per kilowatt-hour; but few of us have realized the benefits of any such price, even on total bills aggregating $20,000 a year. Most rates are based on a service charge and a running charge, and the service charge is generally much higher than the fixed charges placed on isolated equipment. I am assuming that for a mill using 1000-kw. maximum demand, the service charge would probably be $15,000 a year, which is $3000 more than the burden that he places on a 1000-kw. isolated plant. If the service charge is $12 per kw., then the burden becomes the same. Through the advantages of the diversity factor, the central station realizes very much greater revenue from service charges than is at first apparent. I venture to say that if the total maximum demand billed to all customers was added together, it would greatly exceed the actual maximum demand of the central station, owing to the peculiar workings of the diversity factor.

Mr. Kenney refers to plants where exhaust steam can be used, as presenting a more difficult problem for the central station. He could have made a strong point for his case in this particular direction, by showing that few plants use as much exhaust steam as they think they do, and that many use exhaust steam most inefficiently just because they have it, and then console themselves with the thought that they are operating economically. There is many a plant that, if it started with its uses of exhaust steam and reduced them to the actual minimum requirements, would find that the supposed efficiency had disappeared.

With reference to the economic consideration it is hardly fair to compare the central-station requirement of 2000 tons with the mill requirement of 4000 tons. The 4000 tons referred to were admittedly more than should have been the case; and then one must not forget slashers, heating and other equipment which require the use of coal.

It might be interesting, in connection with this paper, to cite the case of a cotton mill having a generating equipment of 1250 kw. and a modern and efficient plant throughout. The heating of the mill was a very considerable item, owing to the peculiar processes carried on. The mill was heated by the use of a hot-water system, the water in turn being heated by live steam on the theory that the temperature of the mill could be nicely controlled with varying temperatures out of doors. Investigation developed that it was possible to heat the water in the hot-water system by using the surface condenser as a water heater; or, to put it another way, by using the water in the heating system as the circulating water for the condenser. It was found possible to vary the temperature of the circulating water by varying the load on the turbine and carrying varying degrees of vacuum. The net result was the production of 300 kw. with the steam previously used for heating purposes alone. It is quite probable that the saving that can be effected during the heating season through this method of operation would justify the operation of the plant the whole year round even in the face of extremely low rates for central-station current.

Engine-Room Design

The engine room is universally recognized as a hazardous department. Admittance is denied even to the initiate except when required by their duties.

It is because of this condition that great care should be exercised to guard against accidents. In many ways this care is noticeable. Engineers are experienced, trained specialists who recognize the potential destructiveness of their machines. Engines are the product of the highest type of engineering skill and have been perfected to an extent equalled in few other branches of mechanical construction. The efforts of the best designers are centered on producing material surroundings within which the heart of the plant may beat safely and with the greatest efficiency.

An engine room should have at least two means of entrance and exit, each of which should be easy of access and within reasonable view of the engineer in charge. (Too many entrances, however, for obvious reasons, are inadvisable.) All passageways and exits should be free of obstructions, and doors should open outwardly and should not be so close to operating equipment as to create a hazard. Basements of engine rooms should have exits so arranged that men may not be trapped in the basement.

A sign should be conspicuously posted outside each doorway forbidding entrance except on business.

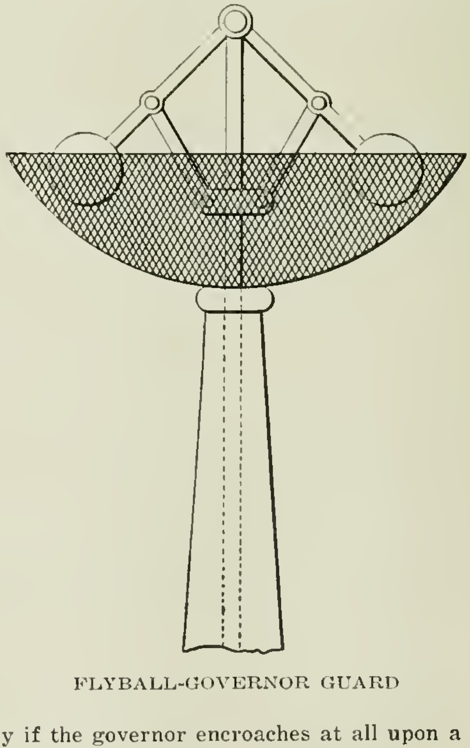
If entrance ways are kept open for ventilating or other purposes, bars or gates should be placed across the entrance.

A gallery for visitors is sometimes provided, as the department exercises a fascination for plant visitors. Entrance to such a gallery is preferable by an outside stairway. If entrance to the gallery is from the main entrance, substantial guard and intermediate rails should clearly prescribe the limit of welcome, and signs indicating entrance to gallery should be displayed. The gallery or balcony should be of fire-resisting construction, rigidly built, and should be securely railed to a height of at least 42 in., with intermediate rails and toe-boards, or the space between the top rail and floor entirely filled in. Conversation between visitors in gallery and engineers or assistants in room below should not be permitted.

Floor of engine room should be of concrete or abrasive surface to eliminate the slipping hazard. When approach is had to any engine or machine, the nonslipping provision should be emphasized. Frequently, inserts or mats of nonslip material are used at these points when the entire floor is not of nonslip material.—*National Safety Council.*

Flyball Governor Guard

A hemispherical sheet-metal or wire-mesh basket strong enough to hold the balls in case of breakage, placed under the flyballs as shown is a useful guard and is absolutely necessary if the governor encroaches at all upon a passageway or a position occupied by an attendant in the performance of his duties.—*National Safety Council.*



FLYBALL-GOVERNOR GUARD

Gasoline Substitute Full of "Pep"

Dr. Lewis Clements, who claims to have produced a substitute for gasoline at a cost of 2¼c. per gal., gave a demonstration in New York on Mar. 19. First of all, the doctor was arrested recently on complaint of a party who had been induced to invest in the substitute that could not, it was claimed, be made for the price stated, and the police agreed to this contention. The district attorney, however, gave the doctor a chance to prove that this substitute would work.

According to the New York *Sun* the thing that sticks in the crop of Assistant District Attorney Renaud is that all the chemists who looked over Doc Clement's formulas said that when it came to producing a low-cost fuel the Standard Oil Co. was an eleemosynary institution compared to the doctor.

They admitted that something ought to happen when all that benzine, alcohol, kerosene, naphtha, sugar and sulphuric acid was poured into a gas tank, but they didn't see how the Doc could make it even at his revised figures of 8c. a gal. They said that solemnly and with forethought, and then put their names after it and went away, so that the Doc was really licked before he started.

It wasn't his fault. He picked things up and put them down, washed them out and then washed them again, sipped kerosene as if he liked it every time he started a siphon working, spilled benzine and alcohol and naphtha all over the place, built little fires and put them out again, and generally had a lovely time. It was the verdict at the ringside that the Doc put up a game fight.

Before the show began, however, the chemists herded the Doc off in a corner and got his formula. Then they deliberated for about an hour and produced the following:

> At the request of Mr. Renaud we have today conferred with a person introduced to us by Mr. Renaud as Louis Clement (they weren't taking any chances), and have received from said Clement a statement of what he declares to be a full and complete formula for his motor fuel.
>
> We know that a motor fuel made according to said formula will cost more than 2½c. a gal., which you stated said Clement represented that it would cost, and further that it would cost much more than 8c. a gal., as said Clement represented to us today.
>
> In our conference with said Clement we noted that he used chemical terms incorrectly, and he did not impress us as possessing scientific or technical knowledge of the subject. Signed: Charles Baskerville, Charles F. McKenna, Gustave W. Thompson, Francis P. Smith, J. C. Olsen, William Gies.

With which deathbed bulletin they all went away save Dr. Gies, who is professor of biological chemistry at Columbia University, and who waited till the bitter end. This pronouncement did not bother Doc Clement a bit. He listened to it being dictated to the reporters waiting to give the news to expectant owners of little flivvers, and then rolled up his sleeves, removed his hat, but kept his overcoat on.

To show that he had nothing concealed about him the Doc permitted detectives to search him in the most approved manner of the stage. He got behind his big board table and proceeded to unwrap, and as he did so it was hard to make out whether the Doc was going to take up light housekeeping or not.

This is what he produced:

Four glass gallon jars
Ten test tubes
Four graduated glasses
Two glass funnels
More corks
One can of alcohol
One washtub
One bottle of cedar oil
Sodium bicarbonate
Weighing scales
Five rubber tubes
Two towels
One pair of scissors
One piece of chamois
Two porcelain spoons
One oil can
One bottle sulphuric acid
Nine corks
One bunsen burner
Two boxes talcum powder
One wash boiler
One bag of sugar
One package of alum
Alcohol stove
Thermometer
More test tubes
Three gallons distilled water
Four gallons kerosene
One suit case

To these were later added a Stillson wrench, an oil stove, which was purchased halfway through the experiment, a cut on the hand acquired by the Doc in opening the kerosene can, a frown and a bad taste from drinking kerosene.

Just to make the scene a bit more reminiscent of Mr. Kellar, Assistant District Attorney Renaud opened some of the packages with an explanation something like this:

> Gentlemen, in this package we have talcum powder, or what purports to be talcum powder. Is it talcum powder? It is. Martini, pour it back.

Hours and hours had gone by and the spectators shifted about, watching the doctor unpack and get ready, and listened to his attorney, William Bosler, explain that the Doc hadn't eaten a thing since the night before and had only slept an hour in four days.

No blushing debutante ever awaited the hour of appearance with greater trepidation than the urbane Dr. Clement. He finally got started about 1:20 and at 1:56 had his picture taken, with cries of "Look thoughtful, doctor!" from the photographers.

He Gives 'Em a Little Action

1:57. Weighs graduated glass excitedly.

1:58. Rubs talcum powder on the graduated glass and puts it down.

2:00. Somebody says, "What does the labor cost?"

2:01. Pours water into a jar.

2:02. Pours it into another jar. Movie machines clicking.

2:03. Puts naphtha flakes, the stuff mothballs are made of, into a graduated glass. More movie activity.

2:05. Little bird up in the rafters says: "Tweet, cheep, tweet."

2:07. Puts sulphuric acid in glass and pours in cedar oil. Stirs it violently while it turns red. Movie men angry because their machines won't take red.

2:11. Assistant district attorney eats a sandwich.

2:15. Mixes oil and water. Somebody explains that the cedar oil gives the car a woody smell so that in driving through Central Park the squirrels will follow the car.

2:25. The Doc siphons kerosene and gets a mouthful.

2:26. Assistant district attorney takes seat on a motor truck to referee the match.

2:38. Drinks more kerosene. Somebody denies the rumor that he has it for breakfast instead of orange juice.

2:40. Makes salad dressing of kerosene and sugar, lights the mixture and then throws it away. Look of perplexity on the faces watching.

2:41. Mixes water and alcohol and burns it.

2:42. Puts benzine in the wash tub.

Then hours and hours and hours while search is made for a stove to heat the mixture which has been consigned to the wash tub. People go in and out and send for more lunch. The stove is produced and the firemen run in a hose from the hydrant outside. Nothing happens. The stuff is stirred up by the doctor with a thermometer and he announces that it is cooked. It is strained and ready for the experiment.

Outside a big two-ton fire truck had been prepared for the experiment. A gallon can with connections all in sight was fastened above the engine and the mixture, which was a pale lemon color, with little bubbles of what a chemist said was water, was poured in. Battalion Chief Marshall superintended this and when the Clement mixture had been poured in, a large husky workman was detailed to turn over the engine.

He turned. Nothing happened. He turned and turned and turned. Still nothing happened. Then he tinkered with the carburetor, and turned some more. Not a kick. The engine was primed and the exhausted cranker relieved by another, but still no response.

Deep gloom and words of indignation on the part of Doc Clement's attorney and friends. The engine should not have been cold; the water in the radiator was cold; it was not fair.

"Let me try the flivver," said the doctor. It was permitted, and with a few deep inhalations the engine raced as if it had picric acid in its innards. Large clouds of smoke drifted from the exhaust and brought back memories of kerosene lamps in the days of one's youth.

One recalled that according to Don Marquis a flivver will run on Stutter's Stomach Bitters, Stewroona, Doctor Bunkus' Discovery for the Kidneys, Lily Gingham's Discovery or Siwash Injun Soorah. It seemed even so.

It was tried on a six-cylinder car with a self-starter and worked beautifully, but all the efforts of Chief Marshall's mechanics would not cause that fire-department machine to cough once. The chemist explained that it was because the water had dissolved and settled to the bottom and no engine will run on water, except apparently a Ford. So the experiment ended, with both sides claiming victory.

But the scientific gentlemen were all on the side of the district attorney, for they showed that all the ingredients in the mixture, with the exception of kerosene, cost as much as gasoline—some of them more. Kerosene costs less, but even that is 15c. per gal., and the Doc claims he can make his stuff for eight cents. He produced at the test from the $9 worth of material about 5 gal. of substitute.

No Strikes or Lockouts During the War

The War Labor Conference, which has been in session at Washington for several weeks, on March 29 submitted to Secretary of Labor Wilson a comprehensive program for the settlement of industrial disputes during the war period, by means of which, if adopted, lockouts and strikes would be averted and production kept at a maximum. Under the proposed agreement, the right of workers to organize in trade unions and to bargain collectively is unreservedly recognized and the open shop is also protected; the basic eight-hour day is recognized; the right of all workers to a living wage is guaranteed; and women doing the work ordinarily performed by men are to receive the pay of men.

In case of disputes there is to be investigation and arbitrament by a National War Labor Board to consist of five representatives of capital and five representatives of organized labor. If the efforts of the National Board fail to bring about a voluntary settlement, provision is made for the appointment of an umpire by the unanimous vote of the National Board. Failing such choice, the name of the umpire shall be drawn by lot from a list of ten suitable and disinterested persons to be nominated for the purpose by the President of the United States. This umpire shall have power, under simple rules of procedure prescribed by the National Board, to make final decisions, from which there can be no appeal.

Ex-President William H. Taft and Frank P. Walsh, selected counsellors respectively of capital and labor, in statements made on Saturday, gave their full approval to the recommendations of the board.

Rules of Procedure

The principles and policies to govern relations between workers and employees in war industries for the duration of the war are stated substantially as follows:

There should be no strikes or lockouts during the war.

The right of workers to organize in trade unions and to bargain collectively, through chosen representatives, is recognized and affirmed.

The right of employers to organize in associations of groups and to bargain collectively, through chosen representatives, is recognized and affirmed.

Employers should not discharge workers for membership in trade unions, nor for legitimate trade-union activities.

The workers shall not use coercive measures of any kind to induce persons to join their organizations nor to induce employers to bargain or deal therewith.

In establishments where the union shop exists, the same shall continue and the union standards as to wages, hours of labor and other conditions of employment shall be maintained.

In establishments where union and nonunion men and women now work together and the employer meets only with employees or representatives engaged in said establishments, the continuance of such condition shall not be deemed a grievance. This declaration, however, is not intended in any manner to deny the right or discourage the practice of the formation of labor unions or the joining of the same by the workers in said establishments, nor to prevent the War Labor Board from urging, or any umpire from granting, under the machinery herein provided, improvement of their situation in the matter of wages, hours of labor, or other conditions.

Established safeguards and regulations for the protection of the health and safety of workers shall not be relaxed.

If it shall become necessary to employ women on work ordinarily performed by men, they must be allowed equal pay for equal work and must not be allotted tasks disproportionate to their strength.

The basic eight-hour day is recognized as applying in all cases in which existing law requires it. In all other cases the question of hours of labor shall be settled with due regard to governmental necessities and the welfare, health and proper comfort of the workers.

The maximum production of all war industries should be maintained and methods of work and operation on the part of employers or workers which operate to delay or limit production, or which have a tendency to artificially increase the cost thereof, should be discouraged.

For the purpose of mobilizing the labor supply with a view to its rapid and effective distribution, a permanent list of the number of skilled and other workers available in different parts of the nation shall be kept on file by the Department of Labor, the information to be constantly furnished: (1) By the trade unions; (2) by state employment bureaus and Federal agencies of like character; (3) by the managers and operators of industrial establishments throughout the country. These agencies should be given opportunity to aid in the distribution of labor, as necessity demands.

In fixing wages, hours and conditions of labor regard should always be had to the labor standards, wage scales and other conditions prevailing in the localities affected.

The right of all workers, including common laborers, to a living wage is hereby declared.

In fixing wages, minimum rates of pay shall be established which will insure the subsistence of the worker and his family in health and reasonable comfort.

Fuel Administration's Fuel-Oil Rules

President Wilson, acting through the United States Fuel Administrator, on Mar. 25, promulgated revised rules and regulations governing the distribution of fuel oil in that section of the United States east of the Rocky Mountains. These regulations supersede those issued Jan. 31, 1918.

Under a proclamation issued by the President Jan. 31, every manufacturer and distributer of fuel oil (including gas oil) whose gross sales aggregate more than 100,000 bbl. per annum was required to secure a license from the Fuel Administration on or before Feb. 11, 1918. The regulations promulgated Mar. 25 control these licensees.

The reason for revising the regulations is that under the former provisions it was found that distributers controlling only a small supply of fuel oil were unable to meet the requirements of all their customers. Distributers controlling larger supplies were able to meet the requirements of all consumers on the priority list. This situation worked a hardship to the customers of the smaller distributers and deprived essential industries of their fuel oil.

Under the new regulations if a distributer is unable to meet the requirements of all of his preferred customers, another distributer may be required by the Fuel Administration to meet this demand before he is allowed to supply his own customers who are not on the preferred list.

Twelve classes of consumers are specified in these regulations, and manufacturers and distributers are required to give priority in the distribution of fuel oil to them in the order in which they are named.

Deliveries must be made in conformity with this list regardless of any existing contracts between licensees and consumers in other classes. After the requirements of consumers entitled to priority are satisfied, licensees must carry out their contracts for other deliveries to the extent of their supplies.

These rules and regulations are for the purpose of assuring an adequate supply and equitable distribution of fuel oil for purposes vitally essential to the national security and defense and to the successful prosecution of the war.

The shortage in the amount of fuel oil which can be delivered, because of transportation conditions, is such that it is clearly a wasteful and unreasonable practice to deliver such fuel oil for uses which are not intimately and directly connected with the prosecution of the war.

Rule 1. No licensee engaged in the distribution of fuel oil in that part of the United States east of the Rocky Mountains shall, without the consent of the United States Fuel Administrator, make any deliveries of fuel oil to any customer or consumer of any one of the classes mentioned below, whether the licensee is under any contract to make delivery to such customer or consumer or not, until such licensee shall have delivered to the customers or consumers of every class designated by a lower number with whom such licensee may have contracts, or to whom such licensee shall have been directed to deliver by order of the United States Fuel Administrator, all fuel oil to be delivered upon such last-mentioned contracts or such orders of the United States Fuel Administrator. Preferential deliveries as between members of the same class may be made only with the consent and under the direction of the United States Fuel Administrator. This rule shall apply to all deliveries of fuel oil, regardless of any contracts therefor or hereafter made.

Provided that this rule shall not prevent the delivery of fuel oil by any licensee to any jobber or distributer if such fuel oil is to be used for a purpose for which the licensee could deliver such oil direct, nor in any case where the jobber or distributer shall have been licensed or designated by the United States Fuel Oil Administrator.

The classes referred to and the order of their preference are as follows: (1) Railroads, bunker fuel and oil refineries using or making fuel oil; (2) export deliveries or shipments for the United States Army or Navy; (3) export shipments for the navies and other war purposes of the Allies; (4) hospitals where oil is now being used as fuel; (5) public utilities and domestic consumers now using fuel oil (including gas oil); (6) shipyards engaged in Government work; (7) navy yards; (8) arsenals; (9) plants engaged in manufacture, production and storage of food products; (10) Army and Navy cantonments where oil is now being used as fuel; (11) industrial consumers engaged in the manufacture of munitions and other articles under Government orders; (12) all other classes.

Rule 2. Licensees shall promptly comply with all orders of the United States Fuel Administrator with respect to the delivery of fuel oil, the submission of reports, and other matters proper and necessary to carry into effect the President's proclamation of Jan. 31, 1918.

Rule 3. Neither these rules and regulations nor the orders of the United States Fuel Administrator shall relieve any licensee from his obligation to deliver fuel oil which he has contracted to deliver as soon as the prevention resulting from such rules, regulations, or orders shall have ceased to operate and the fuel oil shall be available for delivery under such contracts.

These rules and regulations shall apply to all licensees heretofore or hereafter licensed under the proclamation of the President dated Jan. 31, 1918, and shall supersede the rules and regulations issued with the approval of the President on that day.—H. A. **Garfield**, United States Fuel Administrator.

Speaking recently at Dewsbury on coal conservation, W. B. Woodhouse, chief engineer and manager of the Yorkshire Electric Power Co., said that in the United States the production of coal per man was 660 tons, as against 250 tons in Great Britain; in the textile clothing trade, the annual value of the production per person employed in the United States was £484, as against £158 in Great Britain; the primary cause for the difference was that American industry used approximately three times as much power as was used here in corresponding trades. The solution of the problem was the more economical use of fuel and the cheapening of power supply, the one being a consequence of the other.—*Engineering (London).*

Syracuse Garbage-Digester Explosion

An explosion of one of the garbage digesters at the Syracuse Municipal Reduction Plant at about 8 o'clock on the evening of Mar. 20, badly wrecked the plant (Fig. 1), causing an estimated loss of $80,000, but fortunately without loss of life or injury to any of the six men who were employed in the plant at the time.

It is understood that several of the digesters had been installed recently, and that the older ones had all been overhauled during the winter. They had been examined by boiler inspectors a few days previous to the explosion and had been pronounced in excellent condition.

FIG. 1. WRECKED BY AN EXPLODING GARBAGE DIGESTER

The top of the exploded digester, Fig. 2, was thrown several hundred feet over the buildings and landed in an adjoining marsh. No details of the condition of the digesters has been obtained other than that an examination of the drums showed that the plates were much thinner than when first installed and that they were not strong enough to withstand the steam pressure carried, which was not supposed to be over 80 lb. The metal of the drums, which should have been $\frac{5}{16}$ in. thick, had so deteriorated that the plate was extremely thin in places and incapable of withstanding the pressure carried.

FIG. 2. TOP OF THE EXPLODED DIGESTER

It is to be remembered that digesters, although operating under comparatively low steam pressure, are subject to the corrosive action of acids and gases, which causes the wasting away of the plates and greatly reduces the strength of the riveted joints. These are probably responsible for the explosion, although the theory of frozen dynamite having been placed in the digester with the garbage, and that of the explosion of an accumulation of gas and steam in the digesters had been advanced.

Fortunately no fire followed the accident; and as a protection against further danger the fires were drawn from the boiler furnaces and the employees ordered from the building later on on account of the danger from falling walls.

Points About Storing Coal

So many inquiries reach the Bureau of Mines, Department of the Interior, concerning the spontaneous combustion of coal that the bureau has issued the following general statement on the subject. The point of view of the bureau is as follows: The wisdom of establishing large storage piles is, of course, another matter which must be determined from the facts in each case.

The conditions of storage of coal are so various as to make it necessary to apply general principles in each case rather than specific directions.

It is to be recommended that coal should be stored in small quantities as near to the point of consumption as possible. Small coal piles rarely ignite from spontaneous combustion. Coal should be stored near the point of use to avoid rehandling, extra transportation, and the degradation of size which follows each rehandling. For these reasons the bureau would advocate storage, so far as possible, in the bins and yards of the ultimate consumer, thus dividing the risk of loss from spontaneous combustion. If large storage piles are necessary, certain general principles must be borne in mind. The generation of heat is the result of slow oxidation of the coal surface. The oxidation is much more rapid from freshly mined coal or from freshly broken surfaces. The oxidation rate increases rapidly with increased temperature. Different coals have different oxidizing rates. These facts lead to the following recommendations:

Where there is choice of coal to be stored, that having the lowest oxidizing rate should be chosen, if known. Between two coals, that which is least friable, and therefore which presents the least total coal surface in the pile, should be selected. The method of handling should be such as to produce the least freshly broken coal surface. The coal should be as cool as possible when piled. Piling warm coal on a hot day is more likely to produce spontaneous combustion. The coal must be kept from any extraneous source of heat. Alternate wetting and drying of coal during piling is to be avoided if possible.

The fine coal, or slack, which furnishes the larger coal surface in the pile, is the part from which spontaneous combustion is to be expected. Piling of lump coal where possible is therefore desirable. In the process of handling, if the lump coal can be stored and the fine coal removed and used immediately, the practice prevents spontaneous combustion in coals which would have otherwise given trouble.

The sulphur content of coal is believed by many to play an important rôle in spontaneous combustion. The evidence on this point is still conflicting, but to play safe, it is desirable to choose coal having a lower sulphur content, when choice is possible.

There is a current belief that dissimilar coals stored in one pile are more liable to spontaneous combustion. The evidence on this point is also conflicting, but to play safe, it is advisable to store only one kind of coal in a pile. The ground on which a coal pile is built should be dry.

The foregoing recommendations are all derived from the factors affecting the heating of coal.

There should be no spontaneous combustion, whatever the heating rate, provided the heat is carried away as rapidly as produced. This fact brings about the following recommendations: Coal piles should be so made that there is ready movement of air for ventilation throughout all parts of the coal pile. This is the condition when the entire pile is made of coarse lump coal. With ordinary coal piling, this is difficult.

The surfaces of coal piles should be so exposed as to allow the pile to cool; or else the coal should be so stored that air circulation within the pile is very small. When the air circulation is reduced to a minimum, as in an air-tight bin with no opening in the bottom, the oxygen of the air is soon removed and the mass of the coal lies in an inert atmosphere, except for small local circulation near the surface. Air-tight bins are usually impracticable, but the following practice is recommended to approximate these conditions:

In making a coal pile of mixed sizes, the coal should be so handled as to make a homogeneous pile and prevent the segregation of coarse and fine coal. This frequently determines the most desirable machinery for unloading coal.

It is common practice to limit the height of a coal pile; this for two reasons: A pile too high crushes the lower layers of coal, producing more fines; the larger the pile the less heat-dissipating surface there is exposed in proportion to the heat-generating capacity of the pile. Twelve feet in height is a common limit.

Whatever precautions are taken in the choice and handling of coal, provision should be made for keeping track of the temperature rise in a coal pile and for rapid rehandling of portions of a pile in case of excessive heating. In a coal pile covering a considerable area, it should be so subdivided that in case of spontaneous combustion of a portion, the heat will not be transmitted to the whole pile, thus accelerating the heating of portions of the pile which normally would have remained cool.

To keep track of the temperature of coal piles, it is recommended that half-inch iron pipe be driven vertically into the pile at distances of fifteen or twenty feet apart. A maximum thermometer lowered into the pipe to varying depths will indicate the temperature of the pile opposite the thermometer.

A survey of the pile and a survey of the temperature of all parts of the pile should be made twice a week during the first three months after the pile is made, and once a week thereafter until the pile has evidently ceased to heat. As soon as any portion of the pile reaches a temperature of 150 deg. F. provision should be made for removing that portion of the pile. Actual removal need not begin until the temperature has reached 180 deg. F., but at these temperatures the rate of oxidation is dangerously rapid. The object of rehandling the coal is to allow it to cool below a dangerous temperature. Any method of rehandling which does not allow of cooling will only transfer the difficulty from the old pile to the new one. It is generally useless to employ water in an attempt to cool a coal pile.

Lack of provision for rapid reloading, cooling and repiling of coal is the cause of serious loss from spontaneous combustion.

Zone Distribution for Bituminous Coal

United States Fuel Administrator Garfield on Mar. 30 signed formal orders instituting the zone system of distribution for bituminous coal. Twelve general orders, imposing upon the movement of coal the limitations arranged by the Fuel Administrator and the Director General of Railroads were issued. They will be communicated at once to those charged with the enforcement of the zone-system distribution plan. Each order covers a single consuming zone.

The orders of the Fuel Administrator are directed to the operators in the various producing fields, which are limited in their shipments to specified consuming territory. They are supported by embargoes imposed by the Director General of Railroads on all coal movement except along the lines laid down in the zone-system plan.

The orders directing coal producers to restrict their shipments to the coal-consuming territory alloted to them became effective at 7 a.m., Monday, Apr. 1.

The Municipal Electrical Association, comprising 187 towns in England, has been discussing the question of linking up stations, so that one can assist the other with current if necessary. In this connection it is proposed to divide the country into 16 areas.—*Commerce Reports.*

Electrical Energy from the Volterra "Soffioni"

The large works of Count Larderel for the recovery of borax from the hot springs that abound in the volcanic district to the south of Volterra have long been known. There the volcanic district for many miles round is punctuated with *soffioni*—blasts of hot borax-bearing steam which breaks through the natural crevices of the soil.

For many years it was only for the recovery of the borax that this steam was utilized, but of late a new departure has been made which is interesting both for the ingenuity of the methods devised for overcoming technical difficulties and for the importance it may reach.

The earliest experiments for utilizing the Volterra steam for producing power date back to 1903, when Prince Ginori-Conti had a powerful jet of natural steam directed onto the vanes of a waterwheel, but the apparatus was little more than a toy. Later on he used the steam in a reciprocating engine which sufficed to drive a small dynamo and provide current for a few lamps. Encouraged by the development of these experiments, the prince set up a larger engine of 40 hp., which also was actuated by the natural steam just as it rose from the ground. The results obtained were satisfactory in a way, but the rapid corrosion of the metal work by the sulphuric acid and other impurities that contaminated the raw steam were a serious drawback. However, in the hopes that this obstacle might by some device be overcome, several borings were made reaching from a depth of from 100 to 180 meters (328 to 590 ft.), in which iron tubes, of a bore varying from 20 to 40 centimeters (7.87 to 15.75 in.), were fixed. Jets of superheated steam were thus obtained in large quantities. The production of the several shafts varies from 5000 to 20,000 kg. (11,023 to 44,092 lb.) of steam per hour, the pressure from 2 to 3 atmospheres (29.4 to 34.1 lb.), while if the aperture of the tube is completely closed the pressure rises to 4 or 5 atmospheres (58.8 to 73.5 lb), and the temperature ranges from 150 deg. to 180 deg. C.

This source of possible power is clearly important in quantity, and is susceptible of great development, for experience shows that shafts can be sunk as close to each other as are the oil wells in a Pennsylvanian field without interfering with their respective production, and the ground in which they can be sunk with good results extends over several square miles. But before this source of power could be made commercially available some means had to be devised for getting over the corrosion of the metals in the apparatus used.

The first attempt on anything like a large scale was made with a jet of 25,000 kg. (55,115 lb.) of steam per hour at a pressure of 2 atmospheres (29.4 lb.). Theoretically, this would provide about 4000 hp., 40 per cent. of which could be practically utilized. What was actually done was to install in 1912 a turbine of 300 hp., coupled to an alternator, providing a current sufficient for lighting the Larderel establishment. The results obtained were considered good enough to justify the erection of a plant on a larger scale, and the huge increase in the cost of coal caused by the war, owing to which coal has actually been sold on the wharves of Genoa up to £20 ($97.33) per ton, provided an additional motive for pushing on the work. Three turbines were built by Tosi, of Legnano, coupled to alternators for the production of 3000 kw. each. The corrosion problem was tackled in this way. The steam from the *soffioni* was not sent direct into the turbines, but was used to heat three groups of low-pressure (1¼ atmospheres or 18.37 lb.) tubular boilers supplied with pure water, the condensed steam being collected for the recovery of the boracic acid and the other byproducts which it contains. The boilers that produce the steam for feeding the turbines are vertical and the tubes are of aluminum, as being less affected by the acids contained in the steam which provides the heat for boiling the water in the secondary boiler. Each of these turbines develops about 4000 hp., and they are coupled to three alternators of 3000 kw. each. The electric current, which by the transformers is raised to 36,000 and 16,000 volts, is distributed by five distinct lines to various towns. Last summer only two of the groups were used, the third being held in reserve, but other turbines were under order, and the power produced will probably be largely increased in the near future. The latest information to hand is that the company has sold more power than it can at present produce. It is in contemplation to provide motive power from this source, in substitution for coal-raised steam, to the two important steel works situated on the cost at Piombino—the Alti Forni and the Magona d'Italia. A scheme of treatment is also under consideration for the recovery of helium and other rare gases, which may be used for the making of electric lamps and other purposes.

Of the economical results of the scheme it is as yet too early to say anything positive. Even if the management were willing to divulge them, it is hardly likely that it has yet been able to determine their costs with any accuracy. With coal at its present price almost any source of energy may be scrambled for, but when normal times return the question of finance will assume a different aspect, and the plant now working must therefore still be looked on, from the profit and loss point of view, as something of an experiment, though the able men who work it are not lacking in confidence. It will take a longer experience to determine, not only the ultimate efficiency of the plant, but also what will be the cost of repairs for boilers working under the trying conditions to which they are subject. How will this cost compare with that of water turbines?

For the technical details of these notes and the illustrations we are indebted, says the *Engineer*, to Engineer Professor Luigi Luiggi, inspector of the Genio Civile, and an authority of unquestionable competence.

If the War-Savings and Thrift-Stamp campaign attains the goal set, it will cover the entire cost of the Government's shipbuilding program for the year. Already the Government is receiving from the buyers of War-Savings Stamps daily, enough money to build more than 10,000 tons of shipping. It has already received funds for the building of 420,000 tons or 84 ships of 5000 tons each.

STEAM FROM EARTH FISSURES, STEAM-PIPE LINES AND STEAM JET ISSUING FROM A PIPE

Water-Power Legislation Agreement Made

It is understood in Washington that the Special Joint Water Power Committee of the House of Representatives has agreed to incorporate in the Shields bill, passed by the Senate some time ago, all the features of the so-called Administration water-power bill agreed upon by the committee. The Shields bill, when it passed the Senate, was referred to the House Committee on Interstate and Foreign Commerce, and that committee has referred it to the special committee which has been holding hearings on the Administration bill for some time.

Senators are expressing satisfaction that a way has been found out of a legislative difficulty, by the special committee of the House deciding not to bring in the Administration bill as a separate measure. Some Senators have entertained the idea that as the Senate has recently dealt with water-power matters and officially expressed itself in the Shields bill, there would be little opportunity for substituting the Administration bill from the House for the Shields bill in the Senate. The plan now is for the House to amend the latter bill by incorporating the features of the Administration bill. The bill as so amended will then be submitted to conferees on the part of the House and Senate. Senator Shields will be manager of the conferees on the part of the Senate and Judge Sims, chairman of the House Special Committee, will be manager on the part of the House. It is authoritatively stated in Washington that Senator Shields has made up his mind to accept a number of the most important provisions of the Administration bill when they are tacked on to his bill as amendments, and there is a general disposition among other Senators to urge the measure to completion.

The measure must nevertheless go through a number of slow-moving processes before coming to be a law, as in all likelihood there will be debate on it in the House and in the Senate. It is said in Washington that if there is a disposition in the House to retard the passage of the bill unduly, a rule will be brought in by the Rules Committee, shutting off debate.

Brief additional hearings were held on the bill Thursday, Apr. 4, before the House Special Committee. As this is written in Washington, however, the committee feels that it has had laid before it practically all the facts upon which it needs to act.

Marking Packages for Express Shipment

The express companies have issued what is termed Supplement No. 5 to Official Express Classification No. 25. This refers to the marking on packages, bundles, etc., and it goes into effect May 1, 1918. Some of its requirements, which may be of interest to *Power* advertisers and readers, follow:

(a) Each package, bundle or loose piece in a shipment must be plainly, legibly and durably marked, showing the name of only one consignee, and of only one station, town or city and state to which destined.

(b) Shipments wrapped in paper, or packed in boxes, crates, barrels, corrugated paper or fiberboard containers must be marked with pen, brush, stencil, waterproof crayon, or by label securely attached with glue or equally good adhesive. Such shipments must not be accepted when marked only with tag except as provided below:

Shipments of iced goods, such as fish, oysters, etc., must be marked with brush, stencil or waterproof crayon, or with two tags securely tacked, one of which must be sunk in a groove in the box or case, or otherwise protected in such manner as to prevent becoming detached or defaced by contact with other articles or surfaces.

Containers which are customarily used several times for transportation of goods by express, such as bread boxes or dog kennels, which cannot be satisfactorily marked with brush, stencil, waterproof crayon or label, may be accepted when bearing two address tags securely attached to the package.

(c) Castings, machine parts, shafting, pipe, rods, bars, and other metal articles:

1. When boxed, barreled, crated or trussed, must be marked in compliance with paragraph *(b)*.

2. When not boxed, barreled, crated or trussed, and there is sufficient smooth surface for the purpose, the address must be plainly marked on the article with durable paint. Such shipments must not be accepted unless marks are thoroughly dry.

3. When not boxed, barreled, crated or trussed, or when not possible to mark as provided in preceding paragraph, shipments must be marked with not less than two wooden, leather, metal, cloth, rope stock or sulphite fiber-tag-board tags. Rope stock or sulphite fiber-tagboard tags must test not less than 14 point, 50 per cent. rope, have reinforced metal eyelets and cord must be attached by wire not less than 23 gage, or strong tarred cord. Tags must be attached wherever possible to unexposed parts of the article in order that they may not become detached in handling.

4. Rods, shafting, bars, iron-bed slides, automobile springs and other articles of like character marked with tags as provided in paragraph 3 must have the tags securely wired to the article, and in addition, a concealed tag bearing the same address, must be bound to the article with burlap covering, the latter securely wired at each end.

5. When metal articles are shipped in sacks, the address must be shown on tag conforming to the specifications in paragraph 3, attached either by wire or strong cord, and an additional tag bearing the same address must be inclosed in the sack.

Except when in carloads, each package or article in a lot shipment must be marked in compliance with these requirements.

Shipments not marked in accordance with the foregoing requirements, or as noted under individual items of the Classification, must be refused.

Petroleum in Britain

Lord Cowdray has addressed a letter to the press which requires the most careful consideration, both of the government and the public. It appears that he has offered on behalf of his firm to (1) place at the government's disposal the services of his technical staff for the duration of the war, for the purpose of investigating and exploiting oil fields in Great Britain, entirely free of cost; (2) to survey, drill and exploit at their own entire cost, subject to certain areas being reserved to the firm as licensees, who will spend at least £500,000 ($2,433,250) on the work. Thus the nation would incur no expenses, but would stand to gain both directly and indirectly. The point that requires most immediate attention is the statement that legislation is required; otherwise if the government proceeds under the Defense of the Realm Act, all discoveries made and work done would revert to the landowner after the war. That should not be. If petroleum exists in these islands in any quantity, it should be made national property. — *The Engineer.*

Production of Fuel Briquets

The output of fuel briquets in the United States in 1917 was 406,856 net tons, valued at $2,233,888, an increase over 1916 of 111,701 tons, or 38 per cent. in quantity, and of $788,226, or 55 per cent. in value, again breaking the record of the previous year.

According to C. E. Lesher, of the United States Geological Survey, Department of the Interior, the demand for fuel in 1917 was so strong throughout the whole year that there was no lack of market to limit the production of the briquet manufacturers. Despite the increased cost of binders and of manufacturing, most of the plants operated to full capacity and reported a prosperous year.

Obituary

Merrick M. Childs, for 22 years manager and superintendent of the Metcalf Building, Providence, R. I., died at his home at Edgewood on Mar. 31, after an illness of three weeks. His health had been poor for about two years. He was treasurer of the National Association of Stationary Engineers, No. 1 for 17 years, and previous to that had been president for three terms. He was a director of the Nichols Manufacturing Co. and also a Civil War veteran. He was born in Woodstock, Conn. He is survived by his widow and one daughter.

Personals

H. O. Savage has been elected vice president of the Locomotive Pulverized Fuel Co. of New York. He will also continue as vice president of the American Arch Co.

George M. Keenan, formerly test engineer of the Union Electric Co., St. Louis, Mo., is now chief engineer of the Little Rock Railway and Electric Co., Little Rock, Ark.

Henry A. Stringfellow has resigned from the Epping-Carpenter Pump Co., Pittsburgh, Penn., to accept the position of first assistant engineer with R. Winthrop Pratt, consulting engineer, on the design of the new filtration plant for the City of Detroit, Mich.

Engineering Affairs

The American Association of Engineers will hold its fourth annual convention in Chicago, May 14.

The Southwestern Electrical and Gas Association will hold its annual convention at Galveston, Tex., Apr. 15-16.

The Southwestern Society of Engineers wil hold its annual convention at Douglas, Bisbee and Tuscon, Ariz. Apr. 18-20.

The American Society of Heating and Ventilating Engineers will hold a meeting on the evening of Apr. 15, which will be devoted to "Fuel Conservation."

American Association of Engineers—Garrett P. Serviss, the prominent scientist and author, will address the New York Chapter at its next meeting on Wednesday, Apr. 10, at the Hotel McAlpin, at 8 p.m. His subject will be, "The Glory of the Engineer."

The American Institute of Electrical Engineers will hold a meeting on the evening of Apr. 12. The following papers will be presented: "A Physical Conception of the Operation of the Single-Phase Induction Motor," by B. G. Lamme; "No-Load Conditions of Single-Phase Induction Motors and Phase Converters,". by R. E. Hellmund.

Miscellaneous News

The Northwestern Electric Co. of Portland, Ore., has started the construction of a $1,500,000 additional power plant in this city which will have a capacity of 10,000 kw. or 13,400 hp., with an ultimate development of 40,000 hp.

The City Officials of Seattle, Wash., have decided to make a thorough investigation of all power sites offered recently before awarding the contract for the construction of a new plant. The opinion seems to favor the acceptance of the bid of Grant Smith & Co. for the construction of a plant to cost $2,100,000.

The Northern Idaho and Montana Power Co., Kalispell, Mont., has been sold at public auction for $563,166 to Robert J. Graf, representing the stockholders of the company. His bid was the only one received and was made for him by John L. Roemer, a Chicago attorney. The power company became insolvent some time ago and was ordered sold at auction. The Continental and Commercial Trust and Savings Bank, of Chicago, is the trustee for the bondholders, which has held the deed of trust in order to secure its issue of about $4,000,000 in bonds.

The Nevada-California Power Co. is contemplating one of the longest transmission lines in the country. The company has its headquarters at Riverside, Calif., and has been working out details of its scheme with a view to saving power to railroad companies that have been engaged in hauling fuel to the Nevada Consolidated Companies' plant at Ely, Nev. The 24-hour shift of the company has an equivalent of 20,000 hp., and this could be used to good advantage for a saving of fuel. The Nevada Consolidated now generates its own power with local steam plants, which call for an immense tonnage of fuel that is difficult to deliver in the present congested condition of traffic, and anything that would relieve the company from the uncertainty of getting power would be welcome, even though the cost would be in excess of the present showing. The copper company is mining by the steam-shovel method and concentrating the ores at the rate of 10,000 tons a day. The cost of the installation would be approximately $300,000 for the pole line alone. Before engaging in its construction or entering into a definite contract, the power company would have to secure the consent of the Government for a priority order of delivery for the material required in the construction, as it would be impossible to secure any considerable material without this arrangement. Should the deal become effective, the Nevada Consolidated would become the largest individual consumer of electric power in the West and the electric companies' service would extend over a distance of 300 miles from Inyo county almost to the Utah line.

Business Items

The H. W. Johns-Manville Co. announces the removal of its Memphis (Tenn. office to new quarters at 804-5 Exchange Building, Madison Ave. and Second Street.

Smith Serrel Co., Inc., 90 West St., New York City, are now manufacturing the Pintite rigid couplings for line shafting, which are made in shaft sizes from $\frac{11}{16}$-in. to 4-in. This coupling was described on page 229 of the Feb. 17, 1914, issue and was at that time manufactured by the Thomas Coupling Co., Warren, Penn.

The Hawes Foundry and Equipment Co., with a capitalization of $250,000, has just announced its acquisition of the Central Bronze Co., which concern will cooperate with its other plants in turning out a complete line of bronze valves and fittings. All its products will be marketed and distributed as in the past, through its principals, the John Wilfert Co., of New York, Brooklyn, St. Louis and Buenos Aires.

MacGovern & Co., of 114 Liberty St., New York City, well-known dealers in second-hand equipment, announce the opening of branch offices at Pittsburgh, Penn., and St. Louis, Mo. The office in Pittsburgh is located at 498 Union Arcade, and is under the direction of L. H. Tippins and W. L. Sprengle. The St. Louis office is at 315 North 12th St., and is under the direction of R. S. Fisher, district manager.

The Big California-Oregon Power Co. Dam at Copco, Calif., on the Klamath River has been completed and the reservoir which is formed has been filled. This, together with the construction of a similar dam lower down the river, will give the company a total of 103,000 hp. from this one source. The dam just completed is considered one of the great engineering feats of the country. It is 95 ft. across at the base and 500 ft. at the top. It develops 26,000 hp. and cost $1,500,000.

Trade Catalogs

"The Pump that Manistee Builds." The Maniste Iron Works, Manistee, Mich., Pp. 12; 9 x 6 in.; illustrated. This booklet illustrates the design and construction of the RO TURBO centrifugal pump, made by the Manistee Iron Works, in a most unusual way. Instead of the ordinary series of halftone views of the various features of the pump, the booklet contains a cleverly arranged series of pictures of each part. These are cut out and arranged one over the other so that in turning the leaves the reader sees the pump just as he would see an actual model being taken apart. Thus, turning the first page removes the bearing cap. Turning the next page removes the thrust cap and bearing bracket. Each page in turn shows the pump in a more disassembled condition until the last page shows just the holow pump casing. Not only is this booklet one of the most novel publications ever issued by a machinery house, but it makes the design and construction of the RO TURBO pump so clear that a copy should be in every engineer's library.

NEW CONSTRUCTION

Proposed Work

Mass., Cambridge—The Cambridge Electric Light Co. 46 Blackstone St., is receiving bids for the erection of a 1-story, 30 x 50 ft. addition to its power plant. Noted Jan. 22.

N. Y., Albany—State Dept. of Health will receive bids until May 8, for the installation of heating and illuminating systems in laboratory on New Scotland Ave. H. Biggs, Comr.

N. Y., Buffalo—The Demarest Heating Corporation, 21 The Terrace, has increased its capital stock from $10,000 to $50,000; the proceeds will be used to make alterations and build additions.

N. Y., Buffalo—The Frontier Water and Steam Supply Co., 667 Main St., has increased its capital stock from $40,000 to $150,000; the proceeds will be used to make alterations and build additions.

N. Y., Buffalo—The Lackawanna Steel Co. Hamburg Turnpike, is having plans prepared for the erection of a 1-story, 100 x 190 ft. central turbo generator power plant. Estimated cost, $200,000.

N. Y., Buffalo—The National Aniline and Chemical Co., Abbott Rd., plans to build a power house in connection with its plant. Estimated cost, $8500.

N. Y., Buffalo—The Power Efficiency Corporation, 102 Clinton St., has plans under consideration for additions and improvements to its plant.

N. Y., Jamestown—The Crescent Tool Co., 202 Harrison St., is having plans prepared for a power station to be erected at its plant. Noted Feb. 26.

N. Y., Niagara Falls—The State Reservation Commission is having plans prepared by F. N. Williams State Engr., Capitol, Albany, for a power plant to be erected on Goats Island. Estimated cost, $3,000,000.

N. J., Bridgeton—City has plans under consideration for the installation of an electric lighting plant.

N. J., Newark—Maas & Walstein, Inc., Ave. R., has had plans prepared for the erection of an addition to its power plant and alterations to its boiler room. Estimated cost, $12,000.

N. J., Trenton—City is considering plans for a hydro electric plant to be erected on the Sanhican Creek. J. R. Fell, Jr., City Engr.

N. J. Trenton—J. E. Thropp Sons Co., Lewis St., will receive bids until Apr. 19, for the erection of an iron plant to include a power house, foundry, etc. Estimated cost, $100,000. J. O. Hunt, 114 North Montgomery St., Engr.

Penn., Philadelphia—The Bureau of Yards and Docks, Navy Dept., Wash., will soon award the contract for furnishing and installing at Navy Yard, here, exciters switchboards, cell structures, cell equipment, wiring transformers, etc.

Penn., Portersville—The Fox Coal Co., Brannan, near here, has had plans prepared by C. D. Hall, Engr., Jenkins Arcade, Pittsburgh, for the erection of a power house at its plant.

Md., Baltimore—The Baltimore Manufacturing Co., Monument and Constitution St., is having plans prepared for the erection of a new power station on Central Ave. and Bank St.

Va., Norfolk—The Bureau of Yards and Docks, Navy Dept., Wash., will soon award the contract for furnishing and installing at Navy Yard, here, exciters, switchboards, cell structures, cell equipment, wiring, transformers, etc.

Ga., Valdosta—The Ocean Pond Club House plans to install an electric lighting plant to supply light to the house and grounds.

Ala., Chickasaw—The Chickasaw Shipbuilding Co. plans to build an electric generating plant to cost $750,000 in connection with its shipbuilding plant now under way at Mobile.

Tenn., Columbia—M. R. Sterns, Nashville, and associates, plans to organize a company with $200,000 capital stock, to build and operate an electric generating plant on the Duck River, near here.

Ky., Somerset—The Southern Machinery Exchange is in the market for a 150 kw., direct current, 250 volt belted generator and engine, or direct connected set.

Ohio, Bedford—The Owen Tire and Rubber Co., 1900 Euclid Ave., Cleveland, will build a 1-story, 250 x 250 ft., reinforced, concrete, steel and brick factory and power house; also install a high pressure boiler, steam engine and dynamo. Estimated cost, $125,000.

Wis., Brodhead—The Brodhead Electric Light and Power Co. has had plans prepared by Power Eng. Co., Engrs., 512 Corn Exchange, Minneapolis, Minn., for the erection of a 2-story, 40 x 80 ft., brick and rein.-con. hydro electric plant. K. Guelson, Supt. Noted Mar. 19.

Wis., Superior—E. Kaner has acquired a site and plans to build a plant and will install electric cranes in same.

Minn., Crosby—City voted to issue $76,000 bonds for the installation of an electric-lighting plant.

Wyo., Manville—City plans to build an electric-lighting plant. Estimated cost, $30,000.

Ark., Buffalo—The Dixie Mining Co. will soon award the contract for the erection of an electric lighting and power plant. Address A. C. Barnhart, Wheat Bldg., Ft. Worth, Tex. Noted Apr. 2.

Ark., Delight—B. F. Ryon, Texarkana, has been granted a franchise to build an electric lighting plant here.

Ark., Diaz—The Wilmans Mercantile Co. is in the market for machinery including power plant equipment, crusher, etc.

Ark., Hominy—The Hominy Icc, Light and Power Co. is in the market for machinery including a 150 hp. gas engine, direct connected to a 100 kw., 3 phase, 2300 volt generator.

Ark., Rector—The King Mercantile Co. is in the market for equipment for its power plant and cotton gin. About $25,000. L. King, Pres.

Tex., Texas City—The Texas City Electric Light and Power Co. plans to build an electric power station; also install a 100 kw. turbo generator with convertor, for street railway service and an emergency unit. R. C. Trubex, Mgr.

Okla., Blackwell—City plans to install additional electric lighting equipment. Estimated cost, $82,500.

Okla., Ferguson—The Blaine County Salt Co. plans to install electrical equipment in its new salt plant.

N. M., Columbus—The Columbus Electric Light and Power Co. plans to build a power plant here. Estimated cost, $30,000. J. L. Greenwood, Pres.

Wash., Seattle—The Rothert Process Steel Co., 622 Harriman St., plans to install a 10 ton electric furnace.

Calif., Oakdale—The Sierra and San Francisco Power Co., 58 Sutter St., plans to rehabilitate its old hydro-electric plant at Knights Ferry. Estimated cost, $10,000. M. C. McKay, Supt.

Ont., Drummondsville—The Dominion Power and Transmission Co., Terminal Bldg., Hamilton, has had plans prepared for the erection of a hydro electric plant. New electrical equipment will be installed. E. R. Coleman, Gen. Mgr.

Ont., Oshawa—Bradley Bros. is in the market for a 5 hp., 220 volt, single phase, electric motor, 170 r.p.m.

Ont., Owen Sound—The Empire Stove & Furnace Co., Ltd., is in the market for three 15-20 and 25 hp., 60 cycle, 550 volt, 3 phase motors, either new or second hand.

Ont., Owen Sound—Keenan Bros., Ltd., is in the market for a 60-75 hp. engine.

Ont., Toronto—The Universal Products, Ltd., 43 Britain St., is in the market for one 5 hp. and one 10 hp., 230 volt, direct current, medium speed motor.

Ont., Toronto—E. Whiting, 122 King St., E., is in the market for an 18-30 hp. steam traction engine.

Que., East Broughton—The Quebes Asbestos Co. plans to spend $30,000 for a power plant.

CONTRACTS AWARDED

Mass., Boston—The Tilestone and Hollingsworth Co., 49 Federal St., is building a reinforced concrete transformer house. Electric motive power is being installed.

Mass., East Hampton—The Glendale Elastic Fabrics Co., 52 Union St., is building a 1-story, 65 x 75 ft. power plant and switchroom. Estimated cost, $10,000.

Mass., New Bedford—The New Bedford Textile Co., 247 Shawmut Ave., is building a 1-story, 25 x 40 ft. boiler plant. Estimated cost, $40,000.

Mass., Springfield—The Undertakers Supply Corporation, Stearns Bldg., has awarded the contract for the erection of a new 25 x 30 ft. power house, to Gour Bros., 20 Woodmont St.

R. I. Westerly—The Narragansett Electric Light Co., Providence, has awarded the contract for the erection of a 1-story, 30 x 72 ft. addition to the gas house of the Westerly Light and Power Co., to the Joslin Lena Co., 20 Mechanic St.

Conn., Hartford—The Pratt & Cady Co., Capitol Ave., has awarded the contract for a 1-story, 30 x 103 ft. concrete and brick boiler room to be erected at its foundry on Cushman St., to Porteus & Walker Co., 13 Forrest St. Estimated cost, $23,000.

N. Y., New Hampton—The Department of Corrections, Municipal Bldg., New York City, is building a power house at the reformatory here.

N. Y., Syracuse—The Swan & Finch Co., 416 Tracey St., has awarded the contract for the erection of an addition to its power house, to F. M. Kimmey, 1007 West Onondaga St.

Penn., Indian Creek—The Mountain Water Supply Co. has awarded the contract for the erection of a 1-story, 31 x 71 ft. power plant, to the Rust Eng. Co. Penna. Bldg., Philadelphia. Estimated cost, $35,000.

Penn., Philadelphia—The Fretz Co., Ontario and Brabant St., has awarded the contract for the construction of a new engine and boiler house, to H. E. Brocklehurst, 512 West Norris St. Estimated cost, $19,000.

Penn., Pittsburgh—The Arrott Estate, Arrott Bldg., has awarded the contract for a new power plant to be erected on Barker Pl. to replace the one recently destroyed by fire, to Rose & Fisher, 821 Penn Ave. Estimated cost, $15,000.

Penn., Pittsburgh—The South Pittsburgh Water Co., Carrick, has awarded the contract for the erection of a new 45 x 115 ft. power house, to the Walker & Curley Co., Trust Bldg. Estimated cost, $35,000.

Ala., Columbia—The Columbia Power Co. has awarded the contract for enlarging its plant at Omussee, to Tucker & Laxton, Inc. Charlotte, N. C. Estimated cost, $500,000.

Wyo., Wheatland—The town has awarded the contract for a 120 kw. generator directly connected and a new switchboard, to the Fairbanks-Morse Co. Noted Mar. 5.

B. C., Vancouver—The Wallace Shipbuilding Co. has awarded the contract for reconstructing the entire power system to the Mudy Rowland Co.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 4, 1918	Individual Apr. 4, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 4, 1918	Individual Apr. 4, 1918
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	5.10@5.85
Barley	3.40@3.65	3.10@4.10
Rice	3.90@4.10	4.10@4.85
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	April 4, 1918	One Yr. Ago	April 4, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties April 4, 1918	Mt. Olive & Staunton April 4, 1918	Standard Apr. 4 1918
6-in. lump	$2.65-2.80	$2.65-2.80	$2.65-2.80
2-in.-lump	2.65-2.80	2.65-2.80	2.65-2.80
Steam egg....	2.65-2.80	2.65-2.80	2.65-2.80
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut....	2.65-2.80	2.65-2.80	2.65-2.80
2-in. screen...	2.15-2.30	2.15-2.30	2.50-2.65
No. 5 washed .	2.15-2.30	2.15-2.30	2.50-2.65

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule

Lost Opportunity

Contributed by H. D. Odell

THE chief engineer was an intelligent and industrious young man, a correspondence graduate. Although only 25 years old, he had already put in eleven years at the game, having entered the engineering field as an oiler in an electric-light plant. In two years he was promoted to the position of night engineer. Attentive to his work and courteous to all, he made friends and a great future was predicted for him. At the age of 25 years he had realized his ambition and was a full-fledged chief engineer in charge of a street-railway power plant. But there was one thing that had never been impressed on his mind and that was "'never to accept favors from drummers."

THE manager of this railway system was a clean-cut, intelligent person and a first-class judge of men in general. This power plant was one of a string of six owned by a syndicate, and the manager was so efficient that the syndicate appointed him general manager of all six plants with headquarters in a larger city. Of course he had to employ a man to take his place in the position he was going to give up. He thought the young chief would make good if given a trial, but he wanted to find out a few things before deciding. He walked into the power house the next evening and, not finding the chief, was told that he was at home and decided to call on him there. He was invited in and found the chief taking down short-hand from his wife's dictation. He expressed his surprise, and the chief told him that he had been studying office work by correspondence for over a year. The manager was so well pleased that he almost told the chief of his intended promotion, but his better judgment prevailed and he decided to try him on honesty first. So, after talking about several proposed changes to be made at the plant, he left. Next day the manager called an oil drummer by 'phone and asked him to visit the chief and try to sell him some oil. The drummer did so, but the chief told him that he only made requisition to the manager, who acted as purchasing agent. The drummer said that he was anxious to place his oil at the plant and that if the chief would use his influence he would divide his commission with him. As he left he shoved a five-dollar bill into the chief's shirt pocket, the latter objecting rather weakly.

The manager visited the power house next evening and after talking with the chief for a while, asked him how his oil supply was and if he would need any soon. The chief stammered and said that he had plenty. The manager left, looking sad.

SEVERAL days later the drummer appeared again and told the chief that the chance he had waited for so long had come and he wanted to get his oil placed in the plant and would pay the chief well. He then said that the manager was going to be promoted and that a new man was to take his place, and when the change was made he expected him to purchase his oil. It would be easy, he said, as the new manager would not be familiar with the run of things for several weeks and the chief could make the change from one oil to the other without any danger and make some velvet besides. When he left he gave the chief $20 and did not have to push it into his pocket.

NOT knowing that he had been selected for the manager's position, the chief fell for the whole plan and upon reaching home told his wife that his influence was beginning to be recognized and then told her the whole story. Her woman's intuition almost saved him, for she begged him to take the money to the manager and order the drummer to keep away from the plant. She told him that the manager might promote him and wanted to know why he had been studying office work evenings for the past year if he did not expect to advance by the knowledge he gained. The chief maintained that the manager had nothing for him or he would have spoken to him before about the change.

The manager appeared at the plant again the next day to give the chief a chance to redeem himself, but the latter would not talk much, and as he felt guilty, he was glad when the manager had gone.

The manager left, a new man took his place and the oil deal was made two weeks later. The first of the next month when the general manager made his visit to the city, he called on the chief and told him he had heard of his little deal in oil, but that he had not entirely lost faith in him and was going to give him a chance to be honest. Then he told the humiliated chief of the opportunity he had lost for advancement.

Spontaneous Ignition of Bituminous Coal

BY J. F. SPRINGER

The author explains how the spontaneous ignition of bituminous coal occurs; cites the results of experiments made to determine conditions favorable and unfavorable to self-firing; gives tests by which to find out whether a certain coal is likely to ignite spontaneously; and points out methods of storing coal to prevent such action.

BITUMINOUS coal will often take fire without the application of a flame. This action is called spontaneous ignition or, more commonly, spontaneous combustion. In times past it was largely a mystery, and even at the present day it is not thoroughly understood in all its details; however, scientific men have learned enough about its causes to remove the cloak of mystery.

FIG. 1. CONCRETE COAL-STORAGE PIT OF THE OMAHA ELECTRIC LIGHT AND POWER CO.

Spontaneous ignition is believed to occur as follows: Bituminous coal exposed to the atmosphere absorbs oxygen slowly, and as a consequence of the oxidation, the temperature rises—slowly, perhaps, but nevertheless the coal gets warmer. Now, the higher the temperature of the coal the more rapidly will oxygen be absorbed from the air, and the more rapid the absorption of oxygen the faster will the temperature increase. Thus, each action accelerates the other until the temperature eventually reaches the point at which the coal will ignite, and spontaneous combustion ensues.

No external application of heat is necessary, though it will doubtless hasten spontaneous ignition. External heating—not necessarily at a high temperature, either—may start spontaneous combustion. For example, coal stored against a furnace wall or over a steam pipe may ultimately take fire spontaneously, although it would have remained safe from such eventuality if the furnace wall or the steam pipe had been absent. It is possible that, under favorable circumstances, coal that is merely warm when stored may develop spontaneous combustion. In the Cape Breton mining region in Nova Scotia the coal piled in heaps on the surface in the winter does not develop spontaneous combustion; but the very same coal stored in Montreal in the summertime in piles of less height is subject to spontaneous firing. It would seem as though the very moderate temperature of the coal due to the summer weather is sufficient to start spontaneous combustion.

Doubtless some coals are much more subject to self-firing than others, so that the conditions which result in no harm in one case will make all kinds of trouble in another. Anthracite seems to be proof against spontaneous combustion; it is bituminous coal that causes difficulty, and some grades give more trouble than others under the conditions of storage.

A very simple test may be applied to determine whether a coal is likely to ignite spontaneously. If it results unfavorably, great care should be taken in storing that particular coal. If the test results are only moderately favorable, caution should still be exercised. One form of test is as follows: Take a convenient quantity of the coal and weigh it pretty accurately. Heat the sample to 250 deg. F., hold it at that temperature for three hours, and then weigh it. If the weight has gone up 2 per cent. or more, the coal is a dangerous one, from the point of view of spontaneous combustion. The sample must be dry coal, the drying being done at about 100 deg. F. During the test a temperature of 250 deg. could be maintained by using a steam coil containing steam at a pressure of 15 lb. per sq.in., gage. Another simple form of test is as follows: Shake one grain of finely pulverized coal for five minutes with 20 c.c. (1.2 cu.in.) of a half-normal solution of bromine. Bromine has a bad smell. If the sample, at the end of the five minutes, has absorbed the bromine and destroyed the smell, then the coal is to be regarded as a dangerous one to put in storage.

The depth of a pile seems to have a good deal to do with the development of spontaneous combustion, according to experiments made in France some years ago. A pile of slack coal was constructed in such a way that its height or depth varied from nothing at all up to 20 ft. The length was 130 ft., and the width at the top was about 3 ft. This pile was under observation for some three months, and every day tests were made at points in its length, to determine temperature conditions down in the pile. The points tested varied in respect to their distance from the bottom; the deeper the pile the greater this distance. Disregarding the low end of the pile, the temperature rose pretty steadily from the beginning to the end of the three-month period. The temperature never got higher than about 160 deg. F. between the low end of the pile and a depth of about 13 ft. From a depth of 13 ft., the temperatures went up until at the deep end of the pile spontaneous combustion took place.

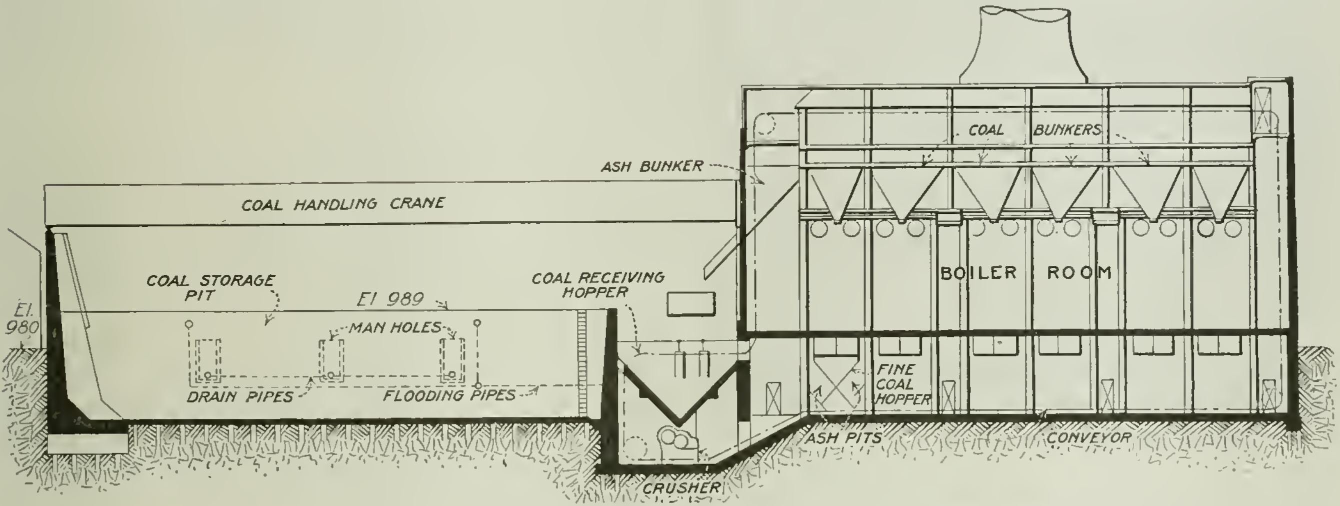

FIG. 2. SECTIONAL VIEW OF STORAGE PIT, RECEIVING HOPPERS, AND PLANT

There is reason to believe that for each and every coal there is a certain safe depth of pile which should not be exceeded. A 10-ft. pile is very likely safe for most bituminous coals, provided other conditions are not unfavorable; but 20 to 25 ft. is probably more or less dangerous for most coals. The New York Edison Co. has a big storage yard at Shadyside, N. J., where coal is stored in long piles which reach heights up to about 35 ft., and spontaneous combustion gives trouble at this yard. In fact, it is probable that most consumers who pile coal to heights exceeding 20 ft. have more or less trouble.

The oxygen absorbed by the coal is taken from the air in the spaces between the lumps, but it has been pretty well established that the amount of oxygen contained in these spaces is too little to account for the total absorption from the moment of storage up to the moment when the coal takes fire. If this is really the case, then there must be a circulation of air into and out of a coal pile. It has been estimated—for a particular case—that an entire change of air takes place once every 9½ hours, which would mean a very slow movement of air. An experiment with a coal pile having a cover with openings that could be closed showed that the temperature rose and fell as holes were opened and closed, respectively. That is to say, when the air supply was cut off, the coal cooled; and when air was admitted, the coal heated. This seems to indicate that if coal could be stored in an air-tight chamber, spontaneous combustion would not develop.

Fine coal is especially susceptible to self-firing, probably because there is much more surface exposed to the air in a ton of fine coal than in a ton of coarse. Wherever air touches the surface of a piece of coal, there is opportunity for the coal to absorb oxygen; so, the larger the surface, the greater the absorption of oxygen and the higher the rise of temperature. It is therefore disadvantageous to have a part of the coal in the form of dust or very small pieces. Such fine coal will naturally sift toward the bottom of the pile, which is a bad position; for it has already been pointed out that deep piles heat up more rapidly than shallow ones.

The circulation of air through coal appears to have a double tendency. First, the circulation continually supplies oxygen, increasing the rate of absorption and consequently the temperature; that is to say, the circulating air tends to promote spontaneous combustion. Second, the circulation of air tends to cool the coal and so operates to retard spontaneous combustion. As these tendencies are opposed, it is necessary to know which will have the upper hand, and that introduces a serious element of doubt. The safe thing to do is to put no dependence upon air made to circulate through a coal pile. It may bring trouble, instead of warding it off.

Another matter that is somewhat obscured in doubt is the effect of storing wet coal. Those who have made inquiries or who have had experience of their own do not seem to be agreed. About a score of years ago in Australia, an experiment was made to obtain information on this matter. Each of two similar bins, placed side by side, was charged with 245½ tons of the same grade of small coal. There was a roof over the bins, but surface ventilation was supplied, and the sides of the bins were of boards with the cracks left unstopped.

In the one bin, the coal was put in dry; but during the loading of the other a stream of water was played on the coal, which was made thoroughly wet, as was indicated by the leakage of water from the bin. Temperature observations were made from day to day in both bins. The temperature of the interior of the dry coal rose steadily until in about sixty days it reached 392 deg. F. in the central part of the coal. The experiment was then halted for fear of actual firing. The coal that was stored wet also increased in temperature until a maximum of 138 deg. F. was reached, after which time the temperature fell.

Paymaster G. R. Crapo of the United States Navy, with an experience gained in a subtropical climate, says that he has handled coal both wet and dry and has discharged vessels in a downpour of rain. He says that fires have occurred with coal stored in both ways, but that less trouble has been experienced with coal stored wet. But this is not the end of the story. A British investigation, by J. I. Graham, resulted in the following conclusion: "At temperatures below 122 deg. F., coal dust, when moist, absorbs oxygen at a rate approximately half as great again as dry dust." This means that under such conditions spontaneous combustion would be markedly promoted. J. Ashworth, lately of Vancouver, B. C., reached the conclusion, presumably from observation and information, that moisture had to be considered and that no gob fire in a mine would take place if the mine were dry and particularly if the air were dry. In years gone by, he was connected with a colliery where the gob heated up and where the coal when stacked above ground was subject to spontaneous firing. He notes that this self-firing "generally occurred soon after the first heavy shower of rain." What is to be concluded in this matter?

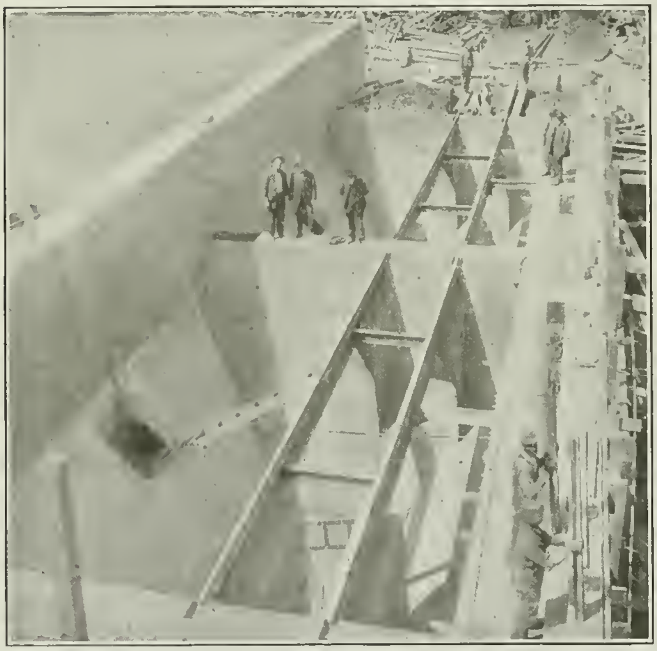

FIG. 3. RECEIVING HOPPERS FOR COAL

An investigation of Illinois coals seems to have favored, for those coals at least, the idea that wet coal is dangerous. "Any coal with conditions favorable to oxidation will be facilitated in that action by moisture. Without exception, in all the series of tests, the wetting of the coal increased the activity, as shown by the ultimate temperature."

The truth of the matter probably is that a little water will promote spontaneous combustion, but that a great deal will check it. But how much is "a great deal"? Is a generous sprinkling, as in the Australian experiment, sufficient? Or must there be complete submergence in a body of water? There seems to be no recorded case of self-firing originating with a coal that was fully submerged in water; but if the coal is merely damp or lightly sprinkled with water, it is probably in a dangerous condition. Old coal mixed with coal freshly mined is understood to be a dangerous combination.

There may exist an impression that spontaneous combustion seldom occurs. In contradiction of this idea, it is on record, according to the officer in charge of the coaling plant, that at the United States Naval Station at Key West, Fla., sixteen cases of spontaneous combustion occurred in a period of less than 100 days. This was during the winter of 1914-15 at this subtropical location. The Canadian Pacific Railway's big storage yard at Montreal has been productive of repeated trouble from spontaneous combustion. The Chicago & Alton R.R. some years ago had a coal-storage pile 10 ft. high, containing a considerable percentage of slack. Notwithstanding the moderate depth, this pile took fire in several places.

Fires due to spontaneous ignition apparently do not occur on the surface; they occur down in the coal. A lighted match or a cigar stub could not very well account for a deep-seated fire. Spontaneous combustion is a real danger in connection with coal storage and can no longer be doubted or ignored. The thing to do is to provide against its occurrence.

There is at least one certain and sure method—complete submergence of the coal in water. Such submergence operates in two ways. In the first place, it cuts off the oxygen supply, which is most important. As the coal cannot get oxygen, there will be no absorption of this gas and no consequent heating. In the second place, the water is sufficient in amount to keep the temperature fairly uniform. There can be no spontaneous combustion unless the temperature rises to the point at which coal takes fire, known as the ignition point.

Complete submergence is neither unheard of nor unused. The United States Navy is using submergence for large quantities of coal at the coaling stations at the Atlantic and Pacific ends of the Panama Canal. Depressed storage floors are provided at both points, and the arrangements are such that from 20 to 30 ft. of t bases of the coal piles on these floors is submerged salt water.

The Underground Railways of London have an electric generating station at Lot's Road. Here a tank for totally submerging coal in quantities up to 15,000 tons has been constructed and put in operation. The tank is of steel and is operated by means of their existing coal-handling equipment. The company has dry storage in addition.

An interesting example of a submerged-storage pit for bituminous coal is that of the Omaha (Neb.) Electric Light and Power Co., in which 6000 tons can be stored under water. Fig. 1 is a general view of the storage pit filled with coal, showing also the crane by which the coal is handled. Between the pit and the power house are two receiving hoppers over which runs the railway siding. A longitudinal section of the plant and pit is shown in Fig. 2. The pit is built of concrete, with walls 22 ft. high on three sides. On the fourth side the wall is 16⅝ ft. higher. This high wall parallels the west side of the power house and not only forms one of the sides of the pit, but also serves as a fire protection for the near-by plant of the Omaha Ice Co. and supports one rail of the crane runway. The other rail is carried on a girder along the side of the power house.

The two receiving hoppers, shown in Fig. 3, are of reinforced concrete, and each has a capacity of 50 tons. The function of the receiving hoppers is to receive coal that is to be consumed at once. As the railway track is directly overhead, it is only necessary to spot the cars at the proper points and make delivery by gravity, with or without the assistance of men. Coal going into storage is taken from the cars by a grab bucket on the crane. As the crane spans both track and pit, the coal may be readily delivered at any desired point. The span of the crane is 143¼ ft. from center to center of wheels. The grab bucket has a capacity of 1½ cu.yd., and the lifting power of the crane is 5 tons. This handling device is guaranteed to deliver 50 tons of coal per hour from the car to the center of the pit.

WALLS AND FLOOR REST ON PILES

The site of the pit is underlaid by quicksand, and so the walls and floor are carried by piles. Apparently all the floor piles, and possibly the wall piles also, reach down to rock and accordingly act more as columns than as piles. The pile heads terminate just beneath the floor, and each is surrounded by a square cap of concrete 2½ ft. on a side and 1 ft. thick. In estimating the loads, the engineers placed the full load on the piles and none on the soil between the piles. There is a certain amount of reinforcement in the floor slab. At the same time it is not a part of the design that the floor shall withstand an unbalanced upward pressure of water beneath it. There is such a pressure, especially when the river is in flood, but the downward pressure of the water and coal in the pit operates against it.

A recent pit for submerged storage is the one built for the Duquesne Light Co. on Brunots Island at Pittsburgh[1]. This pit is 150 by 800 ft. in plan and 25 ft. deep. The bottom is horizontal, but the sides slope at an angle of 45 degrees.

A blanket of carbon-dioxide gas would probably be quite as effective as submergence in water for preventing spontaneous ignition. Such a blanket might be relied upon to remain in the tank because of the fact that its specific gravity is greater than that of air; but it might be necessary to extend the sides of the tank a few feet upward to prevent dissipation of the gas by passing currents and the like.

The things to be done when spontaneous combustion occurs are to dig out the fire and either burn the affected coal at once or remove it to a safe place. Flooding with water is not advisable; for the coal over the fire may coke, and form a dome-like shield capable of affording a good deal of protection against water. At Shadyside spontaneous combustion is dealt with by digging out the fire and sending the affected coal to the power station.

Power-Plant Measuring Instruments

By H. TAYLOR

Plants of, say, 150 hp. or less are as a rule the ones where the absence of measuring instruments is most noticeable. Picture, if you will, such a plant consisting of one 150-hp. horizontal return-tubular boiler operating under forced draft, one pump feeding through a closed feed-water heater, and one injector for emergency use; one 100-hp. automatic cutoff, high-speed engine belted to a lineshaft and one little air compressor tucked away in a corner where no one can get at it, trying its best to do the work of a 50 per cent. larger machine.

The tools usually supplied to such a plant consist of the following: The remains of a No. 7 scoop shovel; one fire hoe with the blade badly burned and loose on the handle; one garden hoe with handle split, to be used for cleaning the ashpit; one iron body wheelbarrow with a large hole eaten through the bottom and one leg loose; a few broken wrenches, a hammer and an old tomato can to fill the oil cups with. The engineer must be on duty at 6:30 a.m. in order to have power on at 7 a.m. He must wheel his coal about fifty feet to the boiler room, do his own firing, including cleaning fires from stationary grates twice during the ten-hour run, and then wheel away the ashes in all kinds of weather. He is responsible for and must look after the boiler and engine plant throughout the entire day and occasionally repair a steam line or splice a broken wire in the mill.

This type of plant is more common than some of us believe, perhaps. Suppose this is the type of plant I am about to take charge of. I get after the manager as follows: "Mr. Manager, I have come to ask your coöperation to the extent of purchasing the necessary implements and instruments that I may conserve fuel, oil and other supplies, thus aiding the Government and benefiting yourself—first of all, a set of good tools, a list of which I submit herewith, that I may be able to do my work quicker and better, thereby giving me more time to study the peculiar needs of the plant. Next, I will need a thermometer to put on the feed line to the boiler—the cost is trifling compared with its value—a boiler-room scales and a water meter, that I may be able to weigh the coal and measure the water to determine whether I am getting a reasonable water evaporation per pound of coal. I would then suggest a gas-analysis instrument to find out whether we are getting the benefit of the greatest number of heat units possible. By the aid of these tools and instruments I can get the boiler plant working more efficiently and save many pounds of coal. For the engine room I will need a few suitable oil cans to save gallons of oil which today costs 'real money.' After making steam economically, we should not fail to use it economically, therefore I will ask you to purchase a good steam-engine indicator that I may make sure the engine valves are set properly and not wasting steam.

"With the aid of these instruments we can tell from day to day just what our power costs, and I feel certain we can reduce that cost, thereby conserving coal and saving money for the company. Now, Mr. Manager, just one more suggestion. If you will allow me access to the vouchers pertaining to my department I will be able to prepare a tabulated cost sheet of the whole power plant."

---

Underground Steam Mains

BY CHARLES L. HUBBARD

This article treats of tunnel and conduit construction. Various types of conduits selected from those in common use are described. Wood conduits are still extensively used where it is desired to avoid the expense of concrete and tile. Insulation of piping.

ONE of the most important details connected with underground steam mains is the form and construction of the conduit. This serves the purpose of protecting the pipe from moisture and also forms a part of the insulation for reducing heat loss. In some cases, as with wooden conduits, both of these offices are combined to a large extent in the same casing, while with those of masonry the walls of the conduit only serve as a protection to the special insulation which surrounds the pipe, tile or concrete in itself offering a comparatively small resistance to the transmission of heat. The forms of construction shown have been selected from those in common use, with the idea of illustrating different types. Some of them are patented, while others have come into general use through the experience of various engineers.

VARIOUS KINDS OF WOODEN CONDUITS

Wooden conduits, the oldest type, are still extensively used where it is desired to avoid the expense of concrete or tile. With some of these the wooden casing forms both protection and the only insulation, while in others an additional insulating filling is placed around the pipe inside the conduit. The life of a wooden conduit depends largely upon the quality of the wood employed and the nature of the soil in which it is laid, whether wet or dry. A typical conduit or casing of this kind is shown in Fig. 1. The main body in this case is composed of a thick wooden wall lined with bright tin and protected on the outer surface by a coating of waterproof asphaltum cement. Solid turned logs are employed for pipe sizes up to 6 in.; larger sizes are built up of staves, put together with mortise-and-tenon joints, coated with a creosote preservative and strengthened with heavy galvanized wire. The thickness of shell varies from two to four inches, according to requirements. The sections are made in lengths of six to eight feet, cylindrical in form, with space inside for rollers and supports. Wood casings of this type have been known to give thirty years of service. Fig. 2 is a section of a conduit of this kind, showing its make-up and method of drainage.

Porous-tile drain pipes are laid below and at either side of the conduit, with a layer of crushed stone between to prevent surface or ground water from settling around the casing. This is an important detail of conduit work, especially where wood is used, as the length of service depends largely upon the degree of dryness which is maintained. Another wooden conduit is shown in Fig. 3, and consists of a tin lining outside of which are layers of asbestos, wood, corrugated paper and, finally, an outer casing of wood staves coated with asphaltum. This form has the advantage of being removable for repairs to the pipe.

A simple form of conduit, often used around railroad yards and industrial plants where the pipes are carried a short distance below the surface, is shown in Fig. 4. The box is of rough lumber, usually about two inches thick, and is set over broken stone with a tile drain below. Any water that finds its way into the conduit is drained off through holes bored in the bottom of the box at frequent intervals. The pipes are supported upon rollers strung on a stay-bolt, also serving to strengthen the box. Stiffening pieces are nailed to the sides and bottom of the box to give it additional support. The life of a wooden conduit of this type in fairly dry soil with the trenches well drained is estimated at 16 to 30 years. One trouble experienced with wooden conduits comes from the great difference in temperature to which they are exposed during the heating and nonheating season. In some cases they shrink or swell, causing serious damage, and sometimes, to avoid this, it has been considered more economical to keep steam on the mains all summer, shutting off the branches to the various buildings just inside the basement walls. The tile underdraining already mentioned appears to be necessary to long life as instances are common where conduits so protected have been found in good condition after 25 or 30 years, while those without underdraining have had to be renewed in seven to ten years.

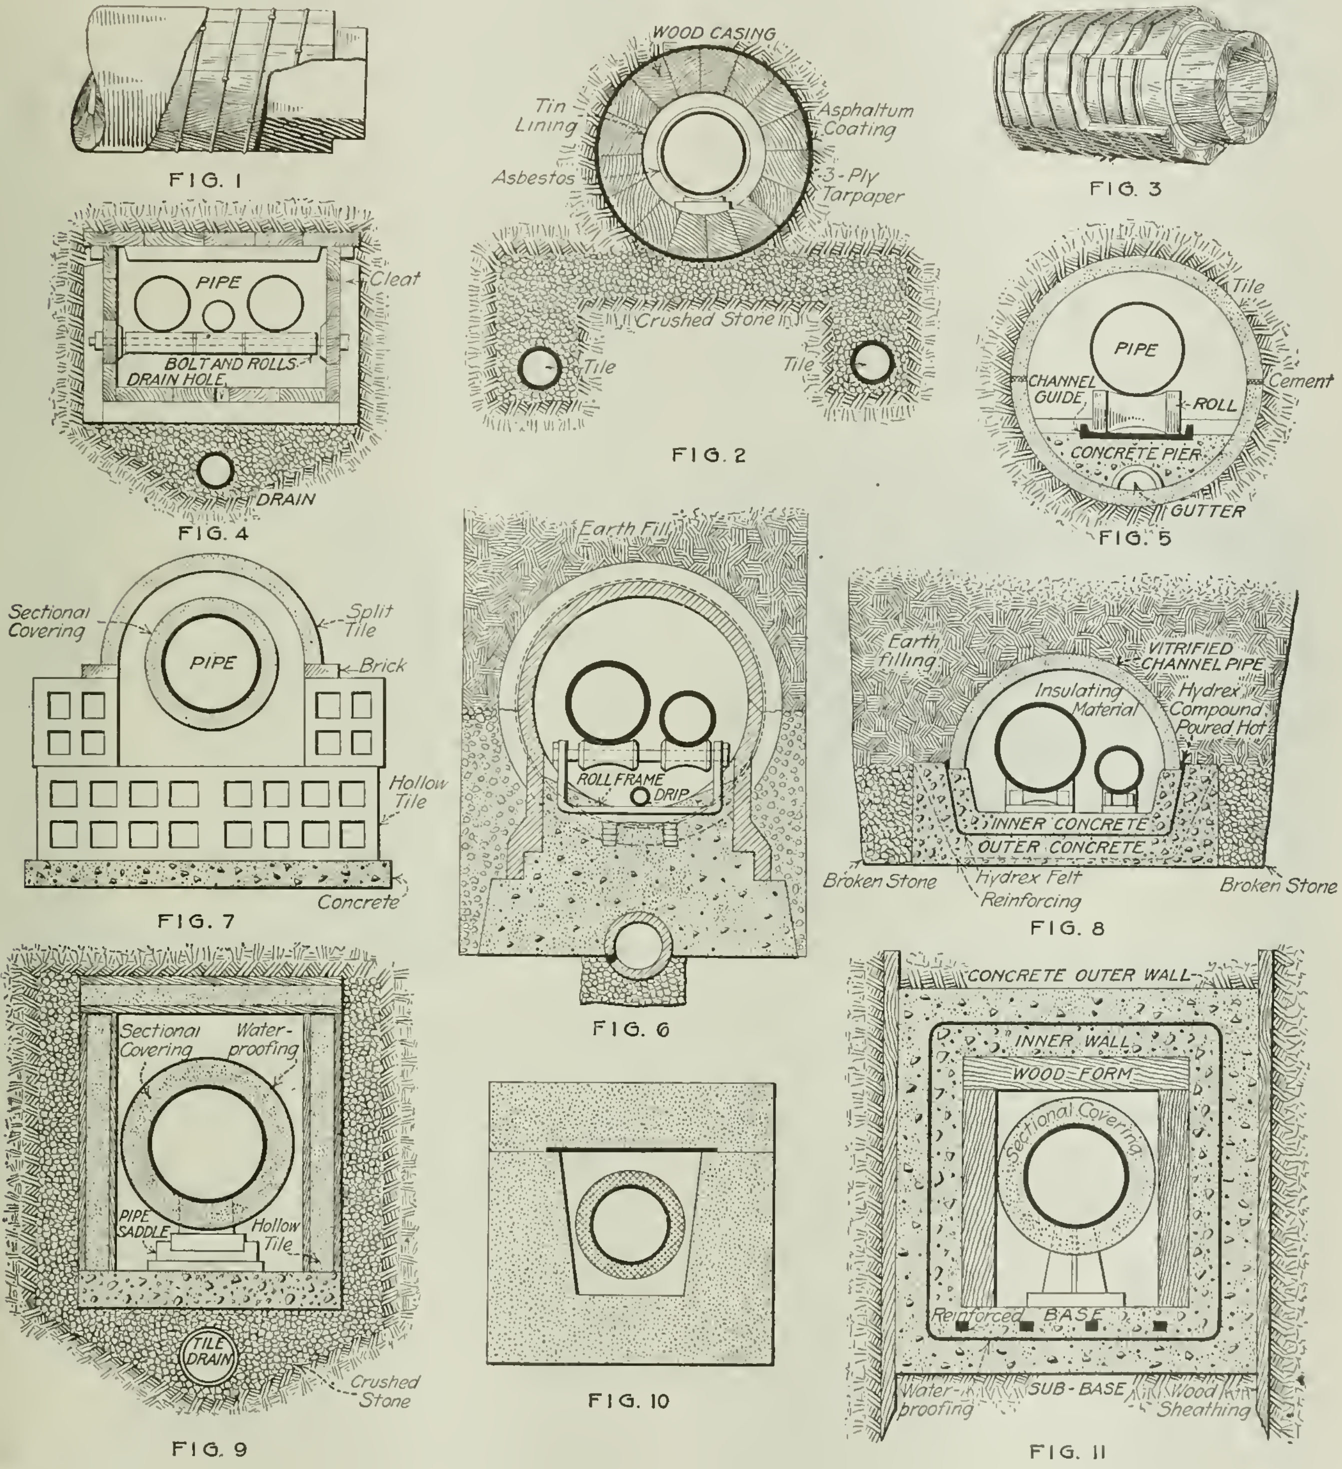
The objectionable points mentioned in connection with wooden conduits have led to the adoption of materials that are not affected by heat or moisture, among which are brick glazed sewer piping, hollow tile blocks, concrete and combinations of these. A well-constructed conduit of masonry is practically indestructible so far as general deterioration is concerned, but is susceptible to the action of frost, the bursting of pipes, etc., which limits its useful life to that of the pipes which it contains unless it be of such form that the top may be removed without damage to the lower half.

GLAZD-TILE CONDUITS

A common form of glazed-tile conduit is illustrated in section in Fig. 5. The lengths are made with longitudinal grooves, which allow of their being split in halves with considerable accuracy after being burned. The lower half is first laid in the trench, after which the pipe is put in place supported upon iron cradles or rollers and the space around it filled with insulating material. The cover, or upper half, is then put in position, the space around the pipe packed with insulating material, completely filling the conduit, and the joints then made tight with portland cement. One difficulty experienced with tile conduits is in supporting the pipe, as bolts cannot be used to hold the saddle in place. A simple device for a single pipe is shown in Fig. 5 and consists of filling in the bottom of a section of the conduit with concrete forming a pier 10 or 12 in. in length, in the top of which is set a piece of channel iron, forming a guide for the roller supporting the pipe. The ends of the pier are raised sufficiently to prevent the roller from falling out of place, and a gutter beneath the pier allows any water in the bottom of the conduit to drain away. When there are two or three pipes to be supported, a saddle or frame carrying the required number of rollers may be built into the concrete base in place of the channel-iron described.

A patented split tile conduit especially adapted to extensive systems of piping is illustrated in Fig. 6. The principal feature is the method of supporting the pipe rollers and anchors by using a tee in the conduit line with the side outlet turned down and built into a heavy concrete base. The pipe support or anchor is embedded in this, as indicated in the illustration. Drainage around the conduit is secured by gravel filling, crushed stone and a tile underdrain.

A combination type of conduit used by one of the largest distributers of steam in their latest construction, shown in Fig. 7, consists of a concrete base upon which is laid a flooring and side walls of hollow tiling carried up to the center line of the pipe and on top a line of brick and over the top a half section of glazed sewer pipe. The joints between the tile in the side walls and bottom are left open to drain off any water that may find its way into the conduit. To prevent a circulation of air from tile to tile in a longitudinal



FIGS. 1 TO 11. VARIOUS TYPES OF UNDERGROUND PIPE-LAYING AND CONDUIT CONSTRUCTION

direction, bricks are set up on edge between the sections, forming dead-air spaces which add to the insulating effect. The steam pipe is covered with sectional covering, and the space between it and the conduit walls is packed with mineral wool.

A patented conduit of special construction particularly adapted to wet locations is shown in Fig. 8. The lower half, which is of concrete, is first constructed and the pipes are laid, after which the tile cover is put on and made tight by a cement dam at the sides and a special waterproofing poured, while hot, into the joints. The conduit shown in Fig. 9 is similar to Fig. 7, except that the sides and top are of hollow tile laid crosswise on a concrete base; this arrangement of the tiling limits the length of the air spaces and prevents air circulation. The entire trench, except the top, is lined with crushed stone, and a porous-tile drain is laid under the center.

One of the simplest forms of continuous concrete conduit is shown in section in Fig. 10. When the trench is dug, a mold is made of boards with a core to form the slot at the center. The concrete is then filled in, forming the bottom and side walls. After this has set for about twelve hours, the core is removed and the pipe may be laid, a strip of sheet iron placed over the slot and the covering layer of concrete filled in. If the ground is likely to hold water long after rain, it is well to coat the sides and top of the conduit with hot coal tar.

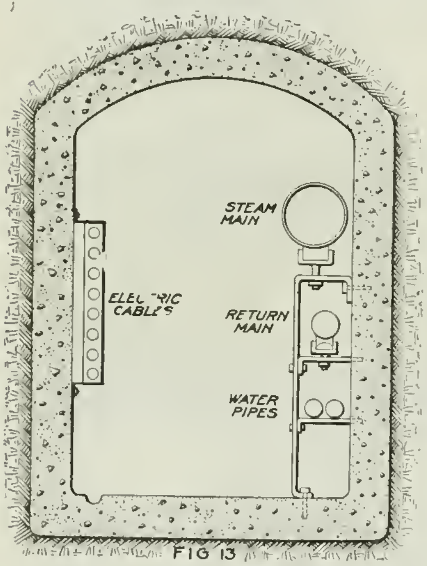


FIG 13

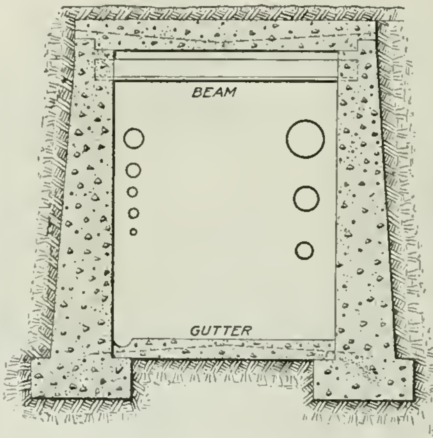

FIG 12

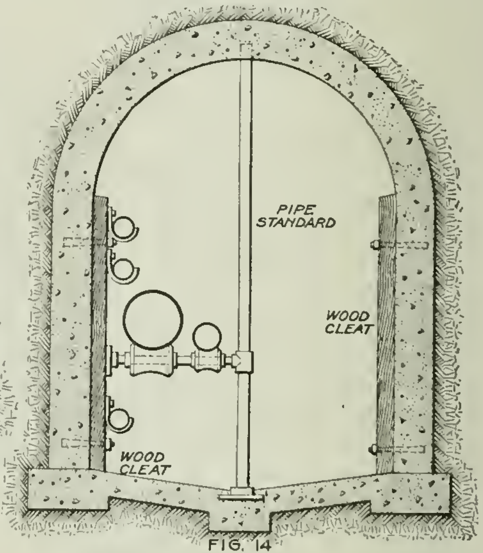

FIG. 14

FIGS. 12 TO 14. TUNNEL DESIGN AND MEANS OF SUPPORTING PIPES AND CABLES

There is no item of greater importance concerning underground heating mains than the protection of the piping from outside moisture. The presence of water in the conduit, especially if it reaches the piping, greatly increases both the heat loss and the deterioration of pipe and insulation, therefore conduits should be thoroughly underdrained with tile laid in coarse gravel or crushed stone, special care being taken to provide a free outlet for the drains to keep the trenches clear of water.

The National District Heating Association has recently made an investigation of different methods of underground conduit construction with special reference to waterproofing and has submitted the type shown in Fig. 11 as one of the best "home-made" arrangements when material and the degree of skill required in its construction are taken into account. In laying this conduit wooden sheathing is driven along the sides of the trench to a distance of at least a foot below the sub-base. Seepage water is kept out by means of pumps and the sub-base and outer walls poured nearly to the top, an inner form of course being used. When this outer shell has set, the inner faces, sides and bottom are brushed with hot asphaltum, a layer of felt or burlap is pressed against it and the surface again brushed with hot asphaltum as before. From four to six layers of this material are used, taking care to give it a good lap, each being joined to the previous one by brushing it over with hot asphaltum. The strips of felt or burlap are run at right angles to the line of the trench and the ends carried well above the sides of the preliminary outside walls and folded back, awaiting completion of the top, or cover. Next, the inner reinforced base is poured, the pipe installed and insulated either by a sectional covering or by packing it in some suitable insulating material. The wooden form for supporting the inner walls and top are left in place, serving as additional insulation. After the inner walls and top are poured, the felt is folded over the top, layer by layer, each being brushed with hot asphaltum as previously described. Last of all the outer or preliminary side walls of concrete are carried up and over to make a complete envelope. Although no under-drain is shown, it is always advisable to provide one if it is possible to secure an outlet at such a grade as to drain away the surface water from around the conduit.

Tunnels have the advantage of accessibility to the piping, but their excessive cost as compared with conduits limits their use to special cases. They are most frequently employed in connecting buildings of an industrial plant where a considerable number of pipes and electric cables are to be put in. Tunnels were formerly constructed of brick, but reinforced concrete is now employed almost exclusively. One form is illustrated in Fig. 12, having a reinforced floor and roof and monolithic side walls. The roof slabs are made in sections and cemented to the walls and are therefore removable. The I-beams just below the roof, for attaching pipe hangers, are spaced 10 or 12 ft. apart. They may, however, be buried in the roof slabs with only the lower flange projecting. Pipes run in tunnels should be carried close to the walls so as to allow a free passage, either at one side or in the center. Fig. 13 shows a tunnel having an arched top and made of solid concrete. Special attention is called to the construction of the rack for carrying the pipe chairs, designed so that sections of the top pipe may be removed directly, while those below must be slid out from behind the front support of the rack, which is not objectionable in the case of small or medium-sized piping. Another method of supporting pipes and cables is shown in Fig. 14, in which pipe standards are erected at the center of the tunnel and cleats are bolted to the wall opposite the standards. Heavy piping is carried on horizontal supports attached to the standards and cleats, while small pipes, cables, etc., may be carried on hooks or other devices fastened directly to the cleats. Special care must be taken in the insulation of tunnel piping and the ends of the tunnel should be tightly closed to prevent any circulation of air which would tend to increase the radiation losses.

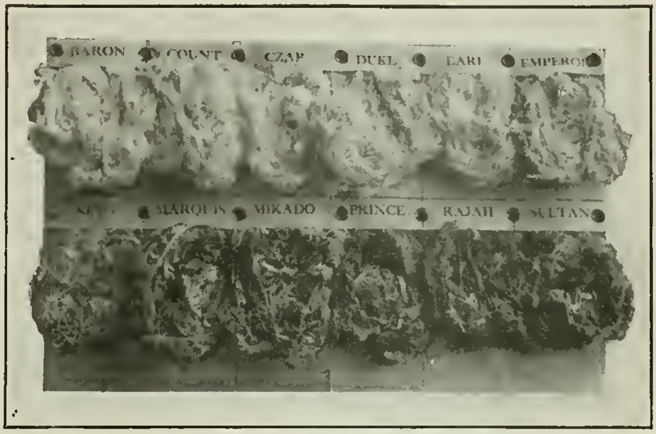
When considering the insulation of a pipe, the entire covering, including the conduit, must be taken into account. Where pipes are carefully packed with suitable nonconducting material and incased in tile or concrete, the efficiency will be somewhat more than for sectional covering, owing to its greater thickness. Conduits of this kind are usually made of such size that the thickness of the insulation shall not in any case be less than three inches, which should bring the efficiency of the entire conduit up to 90 or 95 per cent. The insulating material for this purpose should be especially adapted to conduit work, such as granulated cork, fossil earth, asbestos fiber and ground sponge. Mineral wool may be used when the pipe is protected with some form of sectional covering to prevent the corrosive action of the mineral wool. In the case of brick and concrete tunnels the pipes should be covered with some form of sectional covering that has the property of resisting dampness as well as preventing the loss of heat, for tunnels may be dry in winter, when heat is on, but during the summer, when steam is shut off, moisture is likely to gather. The best grades of sectional covering have an efficiency of 75 to 85 per cent., which refers only to the covering on the pipe and not to the conduit as a whole. The insulating effect of the tunnel will depend largely upon the tightness of the manhole covers and the pipe openings into various buildings. If there is a perceptible circulation of air through the tunnel, the insulating effect of the walls will be neutralized, based on the principle that a dead-air space around the pipes is important in reducing radiation losses. Similarly, in tunnel construction, the circulation of air through it should be kept at a minimum.

"Royal" Family of Waste

What is cotton waste? "The answer to that is simple," say some, yes, probably most engineers. "Cotton waste is the yarn remnants from cotton mills, and we use it to wipe up power-plant machinery. Waste is waste, but what is the idea of the question?"

Waste is not waste; there is as much difference in the grades of cotton waste as there is in shoe leather. As a matter of fact there are many grades of cotton waste, and that which is suitable for one kind of work is not good for another. A good waste should be standardized as to quality, and that is what the Royal Manufacturing Co., Rahway, N. J., has done in the production of twelve grades of cotton waste. Six of these grades are white and six are colored. The illustration shows the sampling catalog on which are mounted a sample of each of the twelve standard grades manufactured by this company. The upper row represents the white and the lower the colored grades.

When an engineer receives this sample card he orders a 100-lb. bale of, say, Duke. Some time later he orders a second bale of the same grade, and it will be the same in quality as the first order because each grade of waste is made from the same prescribed grades of materials which are procured from cotton mills that manufacture a certain grade of cotton or yarn cloth.



SAMPLE CARD OF ROYAL WASTE

A high-grade waste will not leave lint on a machine after wiping it, and it will have the maximum capacity for absorbing oil. A poor grade will possess just the opposite quality. In order to know how to intelligently purchase waste an engineer must know to what use it is to be put and he must also be somewhat acquainted with the grade of waste that is made by the manufacturer of whom the purchase is made.

Some prefer clean white waste, which, of course, is made from white raw material; others favor the use of colored waste, which is made from yarns which have been dyed in various colors. One reason for the preference for white waste is that after it has been soiled the user is more likely to open it up, bringing the clean portion to the outside, thereby using all clean portions before throwing it away as too dirty to use. Colored waste has a soiled appearance to begin with and is likely to be thrown away before it has been thoroughly used; therefore, when purchasing waste a consideration of the type of men who will use it is of importance.

Referring to the illustration, the grade designated as Baron is a fine, long-fibered, high-grade waste suitable for polishing varnished surfaces, etc., and is not recommended for general use. Grades Count and Czar are high-grade wiping wastes and Duke and Earl are for general-utility work and fit the pocketbook as well as the requirements of the purchaser. Emperor grade, although it can be used for wiping purposes, is really not suitable for such work, because it does not give the service, being coarse in texture and is somewhat dirty to begin with. It is usually employed by oil companies for mopping up oil.

The best grade of colored waste, King, is equal in quality to Czar and Duke grades of white waste, at the same price. King and Marquis are for general wiping and are used largely by railroads, as well as in power plants. Mikado and Prince are for general-utility work and Rajah is for rough work such as putting into the journal boxes of railroad rolling stock. Sultan is in the same class as the white Emperor, both being of a low order of the Royal family, being fit only for dirty work. Sultan is for use in foundries for protecting the hands of the workmen when handling the ladles of molten metals, etc., and for starting fires.

Having determined on the grade of waste wanted, the engineer is also interested in knowing how much will be delivered with an order for a 100-lb. bale. That is, how many pounds of burlap, paper and iron hoops is to be paid for at the price of waste. Here is what he receives in the Royal brand of, say, a 100-lb. bale: First, 94 lb. of waste, it does not matter what grade, is weighed in a basket. The burlap wrapper paper and iron hoops are also weighed, the total for each bale being just 6 lb. After the waste has been pressed in a bale, it is again weighed and if there is a gain or loss in weight enough is taken from or added to the bale to bring the total weight up to 100 lb. Therefore the tare on every 100-lb. bale of waste in just 6 lb., no more and no less.

This waste is put up in bales of 25, 50, 100, 250 and 500 lb., but in each case the tare is 6 per cent of the total weight. With this standardization of the bale the engineer knows just how much useless material he is getting with his waste; in some instances with certain dealers the tare runs as high as 14 per cent. of the total weight of the bale.

All raw waste material of the Royal brand is hand-picked and screened; the yarn that goes to make up the grade of finished waste is thoroughly mixed by hand, and the mixture is machined twice to give uniformity of texture. This applies to all grades except the lowest grade of colored waste.

Mono-Rail Hoist Handling Ashes

A few years ago, in most cases ash-handling machinery was "conspicuous by its absence" and the ashes were almost allowed to take care of themselves, so that designing machinery to handle them in old boiler houses is an undertaking that must be viewed from a number of different angles. The device adopted must save labor; its first cost and maintenance must be low, and it should never entail a lot of changes in the old building, with the consequent expense. A mono-rail electric hoist with a bottom-dumping bucket lends itself readily to such installation, especially where the ashes are pulled out on the boiler-room floor. The illustrations show a Link-Belt Mono-Rail Hoist of this type that is giving excellent results in the plant of the Philadelphia Paper Co.

This machine runs on the lower flange of an I-beam track and is operated by a man riding in a trailer cage, who controls the raising or lowering of the bucket as well as the travel of the hoist. The track runs through the boiler house and continues on out over a railroad car on the siding. Laborers fill the bucket, and the operator then hoists it and runs it out over the car, and dumps it by the motion of a lever in the cage. The current required is very small, and the saving in time and labor by this method compared with that of wheeling the ashes is notable. In this instance the superintendent designed his own track supports. It is evident that while he did the work quite cheaply, he made a thoroughly good job of it. About thirty tons of ashes are handled daily, pulled out every six hours. Two men do the work of shoveling into the bucket, and at times one of them gets into the cage and runs it out over the car; at other times, to hurry the work, an additional man operates the hoist, remaining in the cage. The bucket holds 1½ cu.yd. and is handled by a two-ton hoist. The machine is very compact and requires little headroom, and all the gears are entirely inclosed in housings and operate in oil.

TYPICAL USE OF MONO-RAIL HOIST

In places where an overhead coal bin cannot be installed for lack of space, it may then be practicable to use the same mono-rail system to handle the coal as well as the ashes, using either the bottom-dumping or a tipping bucket to discharge coal into the stoker hopper as the case may require, or, sometimes better even, a bucket with a small chute and undercut gate is often used. This problem of handling ashes mechanically is daily becoming more urgent, as many plants are now running twenty-four hours a day where two years ago they were running only ten; hence they have over twice the ashes to handle, with labor scarce. Many plants have stokers and forced-draft systems put in to increase their capacity, without providing for the handling of the ashes.

Some Old Firebox Boilers

By R. E. McNamara

The illustration, Fig. 1, represents one of two firebox type of boilers recently removed from one of the power houses of the Calumet & Hecla Copper Co., Calumet, Mich., the combination of size, age, design and serviceable condition being so unusual as to merit a few words of description.

These boilers are 84 in. diameter, 34 ft. 9¾ in. long and have 52 sq.ft. of grate surface, two 6-in. safety valves and double firebox. Being about forty years of age, they have been discontinued from service, although a test strip cut from one of the shells showed practically no diminution on tensile strength or elongation.

One of the unusual features is the quintuple-riveted butt joint and the rigid head bracing; even in the modern boiler nothing is found, as a rule, above the quadruple butt joint with 94 per cent. efficiency; and when it is considered that this boiler was built in 1878, not only was it a leviathan for its time, but it represents engineering and boiler-making practice which, to say the least, is by no means universal even at the present day. The firebox or furnace of one of these boilers partly demolished is shown in Fig 2.

In explanation of the apparent longevity of these boilers, it might be noted that one of the contributory factors is the remarkable purity of the Lake Superior water and the close attention in care, washing and repairs that the boilers have received since their installation.

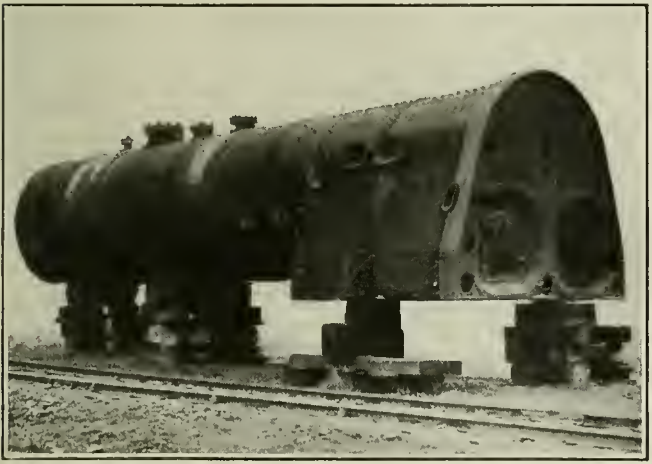


FIG. 1. FIREBOX BOILER REMOVED AFTER 40 YEARS OF SERVICE

Other similar boilers are still in use, but they are limited to comparatively low pressure; that is, around 100 lb. Other and later types in the same power house are of similar design, but are somewhat larger and are allowed 170 lb. pressure.

[Since receiving the foregoing we have obtained some additional information from F. W. Dean, mechanical engineer, formerly of Boston, Mass., and now with the Emergency Fleet Corporation in Washington. In speaking of this type of boiler, Mr. Dean expresses the opinion that the first ones of 90 in. diameter were designed in 1882 or 1883. Mr. Dean made the first drawings of the 90-in. boilers which were designed by E. D. Leavitt at his office in Cambridge, Mass., and were built by Edward Kendale & Sons of that place. The steel was acid openhearth and was rolled by the Nashua Iron and Steel Co., of Nashua, N. H. The nozzles were of steel plate rolled up and flanged, and with thick plates riveted to the flanges.—Editor.]

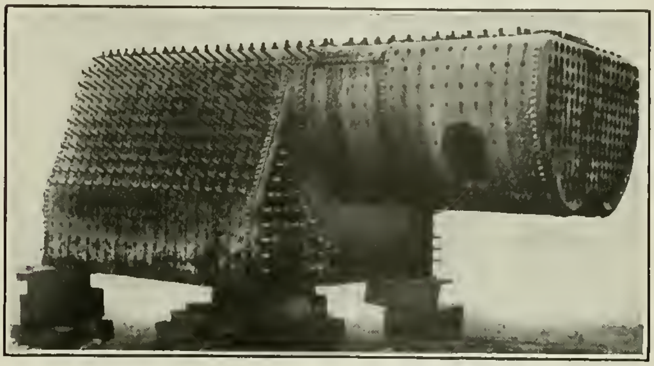

FIG. 2. SHOWING STAY-BOLTS AND TUBE SPACING

Steam-Carrying Capacity of Pipes

Several readers have written, suggesting that it would be of interest to know what formula was used by Mr. Thies in computing and laying out the charts for the carrying capacity of pipes, in the issue of Dec. 18, 1917, pages 825 and 826. Following is Mr. Thies' reply:

These charts were made after a careful study of an article on "Flow of Superheated Steam in Pipes," by E. H. Foster before the A. S. M. E. in May, 1917 (Volume 29 of the Transactions). These charts are good only for short runs of pipes such as mains and branches in power plants and are not figured on a basis of pressure drop. The formula is:

$$A = \frac{2.4PC}{V}$$

in which

A = Area of pipe in square inches;
P = Pounds of steam passing per hour;
C = Cubic feet of steam per pound;
V = Velocity in feet per minute;
2.4 = Constant.

The Continental heat unit, or calorie, is the quantity of heat required to raise the temperature of one kilogram of water one deg. C., and as 1 kg. is equal to 2.205 lb. and 1 deg. C. is equal to 1.8 deg. F., it is obvious that one calorie measures the same quantity of heat as does 3.969 B.t.u. This is shown by multiplying 1.8 by 2.205. It is usual when translating from the English and American standard to the Continental or metric standard of heat measure to call 1 calorie equal to 3.97 B.t.u.

A ready means of remedying leaks in engine casings is by filling cracks with litharge and glycerin.

Parallel Operation of Direct-Current Generators

By T. F. BARTON

The elements that must be considered when operating direct-current generators in parallel are discussed, and the adjustments that may be made to obtain the proper characteristics are pointed out.

ELECTRICAL generators are considered as operating perfectly in parallel when the load divides among the several units according to their rating, this proper division of the load holding as the load varies over the entire operating range of the machine. Parallel operation is considered satisfactory when this perfect condition is approximated within a small percentage.

For successful parallel operation machines must have approximately the same voltage characteristics. It is therefore impossible to operate shunt- and compound-wound generators in parallel or compound machines of greatly different characteristics, although the equalizer used with such machines tends to give each the same effective compounding.

The simplest case of parallel operation in so far as connections and electrical characteristics are involved. is found in the shunt-wound noncommutating-pole type machine, Fig. 4. If two shunt-wound machines are connected together at no load, and no change is made in their field rheostats, then the voltage of both machines will decrease with increase of load, and the two machines will divide the load as determined by their voltage regulation.

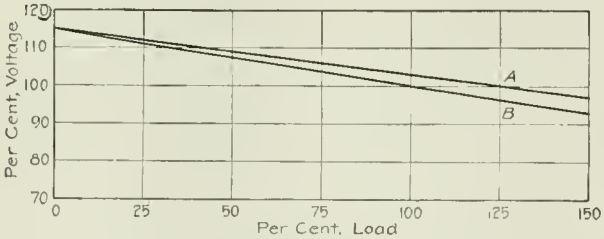

FIG. 1. REGULATION CURVES OF TWO SHUNT-WOUND, DIRECT-CURRENT GENERATORS

As an example, consider two 200-kw. generators operating in parallel, having voltage regulations as shown by the curves *A* and *B* in Fig. 1. A total load of 450 kw. will divide as indicated, 200 kw. on generator *B* and 250 kw. on *A*.

There are three adjustments that can be made to change the regulation of shunt-wound generators:

a. The demagnetizing effect of the armature current on the field poles is proportional to the amount of brush shift. The greater the brush shift, therefore, the broader the regulation. Commutation primarily determines the brush position, and it is unwise to sacrifice commutation for regulation.

b. Increasing the air gap improves regulation, while decreasing it has the opposite effect. Most machines are arranged with shims back of the polepieces, and these may be removed or added to, depending on the results desired. Mechanical dimensions determine the minimum air gap, and field copper the maximum. It should be remembered, however, that the design of a machine determines the proper air gap, and any change from this value may result in some slight disadvantage, but usually not sufficient to affect the operation of the machine in any way except regulation.

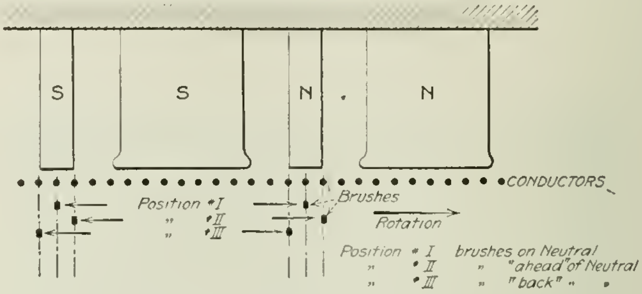

FIG. 2. DIFFERENT BRUSH POSITIONS IN REFERENCE TO THE COMMUTATING POLES

c. A change in speed also affects voltage regulation. Speed changes are to be used only within narrow limits. Better regulation is obtained by lowering the speed or improving speed regulation, or by a combination of the two.

Commutating-pole machines require very careful adjustments if the best results are to be obtained. Connections are shown for a shunt-wound commutating-pole type machine in Fig. 5.

At brush position No. 1 in Fig. 2, the effect of the commutating field is normal with regard to regulation. With the brushes in position No. 2 or 3, a part of the commutating-field flux is not effective for commutation, but combines with the flux of the main pole, subtracting from it with forward and adding to it with backward brush shift.

The voltage generated by a direct-current machine is the sum of the voltages of all coils connected to the commutator bars between positive and negative brush studs. If the brushes were shifted 90 electrical degrees from the neutral position, no voltage would exist between positive and negative studs. Similarly, if the brushes were shifted a few degrees as in position No. 2, Fig. 2, in this position some of the conductors connected to commutator bars between the studs would cut the flux from the commutating field; and since this flux is proportional to the load, the voltage characteristic with forward brush shift is similar to that of a differen-

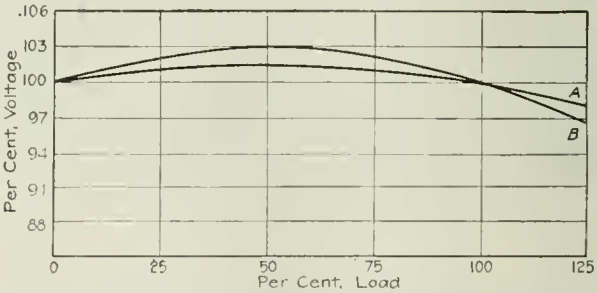

FIG. 3. REGULATION CURVES OF TWO COMPOUND-WOUND, DIRECT-CURRENT GENERATORS

tially wound generator. Backward brush shift is a compounding effect. Brush position and commutating-field strength are definitely related, a backward of neutral position requiring a stronger, and ahead of the neutral a weaker flux. If the brush position is changed, the strength of the commutating machine should usually be changed. This, however, depends on the correctness of the original adjustment. The effect of air gaps, speed and speed regulation, are the same as in the noncommutating-pole type.

An equalizer is used in connection with shunt-wound commutating-pole machines in some instances. Such an arrangement becomes necessary only where the voltage regulation is made very close owing to the compounding effect of the commutating field. The equalizer functions here as in compound-wound machines. An equalizer is undesirable on shunt-wound, commutating-pole machines, since for the equalizer to function, the commutating-pole field strength is necessarily changed from its correct value.

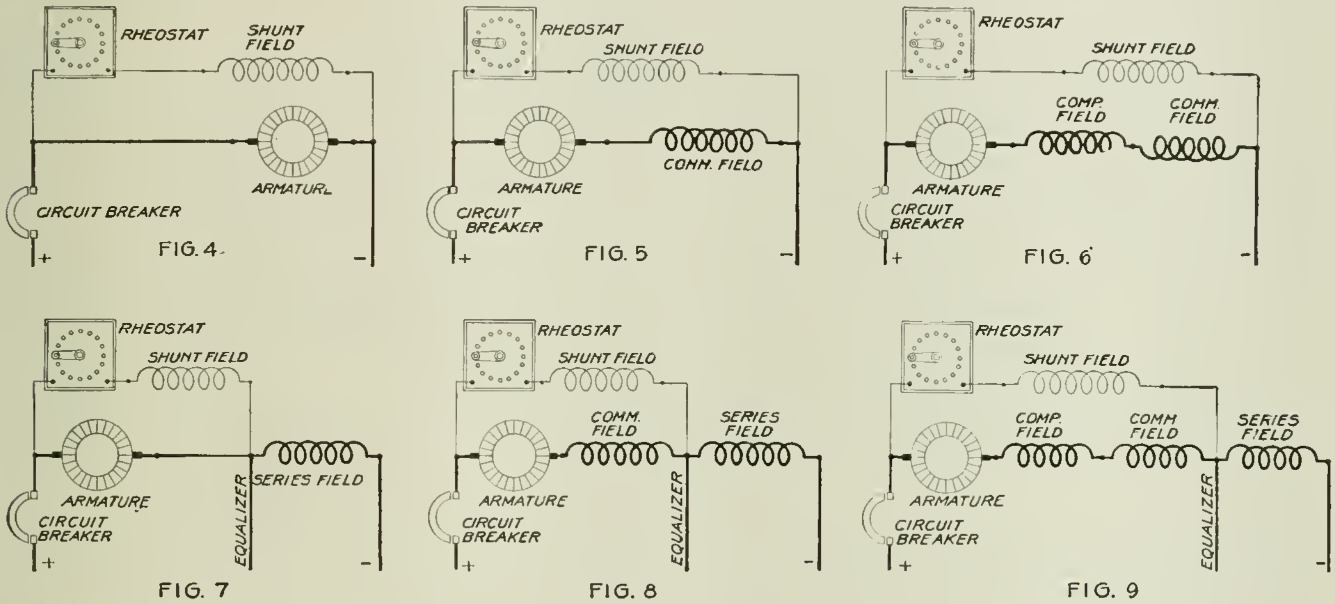

FIG. 4 FIG. 5 FIG. 6 FIG. 7 FIG. 8 FIG. 9

FIGS. 4 TO 9. DIAGRAMMATIC CONNECTIONS FOR VARIOUS TYPES OF GENERATORS

The shunt-wound, compensated, commutating-pole generator is very similar to the commutating-pole type except that, instead of neutralizing the armature reaction only under the commutating pole, it is more or less entirely neutralized by the compensating windings, depending on the amount of compensation. The connection for this type of machine is given diagrammatically in Fig. 6. The effects of brush position, strength of field, etc., are the same as in the commutating-pole type.

To obtain stability in parallel operation of compound-wound noncommutating-pole generators, they must be connected together at points where a drooping-voltage characteristic results with increase of load. The equalizer connection, if made on the armature side of the compound-field winding, will accomplish this result (see Fig. 7).

The compound-field windings with their connecting line cables of all machines in parallel are in multiples between the equalizer and the bus, and it is therefore important that the resistance of these circuits be inversely proportional to the rating of the machines. Resistance is often connected in the line cables for obtaining a proper balance. Resistance should never be connected in the equalizer cable. If the resistances of the field circuit are not properly balanced, the machine with the low-resistance field circuit will take more than its proportion of the load.

The compounding curves of generators vary greatly, and except for the correcting effect of the equalizer, generators with voltage characteristics as shown in Fig. 3 would not divide a load properly between them at any point except zero and 100 per cent. The amount of compounding above a given no-load voltage may be varied by changing the strength of the compound winding, raising or lowering the speed, changing the speed regulation, shifting the brushes, or changing the air gap.

Connections for a compound-wound commutating-pole generator is given in Fig. 8 and the connection for a compound-wound commutating-pole compensated machine is given in Fig. 9. In adjusting these types for parallel operation, the fact that the series field does not necessarily produce all the compounding should be kept in mind. The actual compounding depends on the strength of the compound field, the brush position and the strength of the commutating field. Parallel operation is sometimes difficult even though the voltage characteristic of each generator is approximately the same. The real difficulty lies in the fact that while each machine has the same regulation at the line terminals, each does not have the same regulation at the point of equalization, and the machines may compound entirely from the action of the compound field, while another may compound but slightly from this source, but from the commutating field and brush position. The equalizer cannot be very effective in such cases, since all equalizing must be done by current changes in the compounding-field winding, and if any such field has little or no effect on the compounding, it follows that the equalizer has little effect on the division of load among the machines. The equalizer cable of any machine should be designed to carry not less than 50 per cent. full-load current.

Operating Cost, Tamarack Mills Power Plant

Analyses of cost of operation of the Jenckes Spinning Co. and the Tamarack Mills power plant.

IN *POWER* for Mar. 26 appeared an article setting forth the chief features of the new Tamarack Mills power plant, Pawtucket, R. I. This plant and that of the Jenckes Spinning Co. near-by are two of the most interesting in New England, particularly in the textile industry. At the time the article referred to was written, operating-cost figures were not available; but they are given in the following. As pointed out in the article, both the Tamarack plant and that of the Jenckes Spinning Co. burn fuel oil exclusively in B. & W. water-tube boilers. The former is a high-pressure turbine plant, the latter a reciprocating-engine mixed-pressure turbine plant; both use atmospheric cooling towers for cooling the condensing water.

This is a good time to call the reader's attention to an error in the price of oil for the Tamarack plant. as stated in the article in *Power* for Mar. 26. It was given as 92c. per bbl. of 42 gal. The price paid is $1.15 instead; 92c. per bbl. is the old contract price made about two years ago for the Jenckes Spinning Co.'s plant.

There follows a brief analysis of the cost per kilowatt-hour of generating power in the Jenckes Spinning Co.'s power station and in the Tamarack No. 2 power station. The figures given are actual operating expenses incurred during one week's continuous run. The matter of oil, repairs, supplies, etc., was estimated and then verified by reference to the accountant's books, so that the total over-all cost per kilowatt-hour includes every expense that can rightfully be charged against the operating expenses.

With particular reference to the fixed charges on these two power stations, it is believed that the following figures will serve as an accurate criterion in estimating the gross costs of power delivered to the switchboard. The percentages given are those that are normally used in plants of the capacity, and containing like generating equipment.

Fixed annual charges: Interest, $0.06000; depreciation (annuity basis), $0.03344; taxes (¾ of total cost at 1½ per cent.), $0.01125; insurance, $0.01000; total fixed charges, $0.11469.

The item of depreciation given as 3.344 per cent. is figured on the annuity basis, which is the common practice in plants of this nature. The percentage of the total costs of the plants must be set aside at the beginning of each year, for a period of 17 years (the estimated average life of the complete plants), the same assumed to earn interest during the whole period at the rate of 6 per cent. compounded.

Using the figures given of 11.46 per cent. as the average annual fixed charge on the two plants, the gross cost of power delivered at the switchboards, per kilowatt-hour is as follows: Jenckes Spinning Co., $0.00806; Tamarack No. 2, $0.00782.

Note that there is a difference in the gross cost per kilowatt-hour in favor of the Tamarack plant of $0.00024. This decrease is due to the fact that the items of repairs, supplies, lubricating oil and labor cost 27 per cent. less in the Tamarack plant than in the Jenckes Spinning plant. If, on the contrary, the costs on the two plants were identical, the total net cost per kilowatt-hour in the Jenckes Spinning plant would be somewhat less than in the Tamarack plant, due to the fact that fuel oil costs approximately 28 per cent. less in the Jenckes Spinning Co.'s plant than in the Tamarack plant.

ECONOMY CALCULATIONS OF THE JENCKES SPINNING CO.'S POWER PLANT FOR WEEK ENDING FEB. 23, 1918:

The engine room of this plant contains the following equipment:
One Harris simple engine, 30¾ x 60-in., 66 r.p.m.
One Harris simple engine, 24 5/16 x 48 in., 76 r.p.m.
One 1,000-kw. mixed-pressure turbine, taking exhaust from engines and auxiliaries, in excess of amount required to heat feed water.
One 300-kw. noncondensing turbine, the exhaust steam from which is used for heating feed water and operating 1,000-kw. unit.
One 390-hp. synchronous motor belted to the engines and connected in parallel with the turbines, this motor being allowed to float on the line, sometimes operating as a generator and again as a motor.

	A. Total Quantities:	
1.	Kind of fuel	Mexican fuel oil
2.	Total oil used at 147 deg. F., bbl	1657 3
3.	Total oil used at 147 deg. F., gal	69,606. 6
4.	Weight of one gallon oil as fired, lb	7. 7
5.	Total weight of oil, lb	535,970. 8
6.	Total water feed to boilers, gal	710,600

6.	Supplies	0 0000365
	Total cost per kilowatt-hour	0. 0072165

NOTE.—No allowance made for overhead charges which should be added to "G" to give gross costs.

* The figure of 213,800 kw.-hr. is the net power output after deductions for excitation and other auxiliaries.

ECONOMY CALCULATIONS OF THE TAMARACK CO.'S NO. 2 POWER PLANT FOR WEEK ENDING MAR. 2, 1918

The engine room of this plant contains the following equipment:
One 2,500-kw. bleeder-type turbine.

	A. Total Quantities:	
1.	Kind of fuel	Mexican fuel oil
2.	Total oil used at 149 deg. F., bbl	1,227 8
3.	Total oil used at 149 deg. F., gal	51,567. 6
4.	Weight of one gal. of oil as fired (estimated), lb	7. 7
5.	Total weight of oil, lb	397,070 5
6.	Total weight fed to boilers, gal	594,510
7.	Total weight of water, lb	4,954,250
8.	Total water evaporated, corrected for quality of steam 0.985 (estimated), lb	4,870,000

B. Economy:	
1. Water fed per pound of oil as fired, lb.	12.05
2. Water evaporated per pound of dry oil (estimated), lb.	12.54
C. Cost of Evaporation:	
1. Cost of oil per barrel of 42 gal., dollars	1.15
2. Weight of gal. of oil at 60 deg. F. (estimated), lb	8.02
3. Cost of oil per pound, delivered to tanks, cents	0.342
4. Cost of oil per 1,000 lb. of water evaporated, cents	27.4
5. Cost of 1,000 lb. of water (8c. per 1,000 gal.), cents	0.96
D. Chargeable to Power:	
1. Fuel oil (estimated), bbl	1,050
2. Total cost fuel oil, dollars	1,207.50
3. Water purchased, gal	510,000
4. Total cost water (8c. per 1,000 gal.), dollars	40.80
5. Labor, dollars	153.00
6. Oil, dollars	5.00
7. Repairs (estimated), dollars	50.00
8. Supplies, dollars	6.00
E. Chargeable to Heating:	
1. Fuel oil (estimated), bbl	177.8
2. Total cost fuel oil, dollars	204.47
3. Water purchased (estimated), gal	84,510
4. Total cost water (8c. per 1,000 gal.), dollars	6.76
5. Labor (all charged against power)	
6. Repairs (estimated), dollars	15.00
7. Total weekly heating costs, dollars	226.23
F. Power-Plant Details:	
1. *Total kw.-hr. generated	208,100
2. Load factor of plant, per cent	49.5
3. Pounds of steam per kw.-hr.	20.4
4. Pounds oil per kw.-hr.	1.69
5. B.t.u. per pound oil (estimated)	18,400
6. Over-all efficiency of plant, per cent	10.9
G. Unit Costs of Power per Kilowatt-Hour, Dollars:	
1. Fuel oil	0.005790
2. Water	0.000196
3. Labor	0.000736
4. Oil	0.000024
5. Repairs	0.000240
6. Supplies	0.000029
Total cost per kilowatt-hour	0.007015

NOTE.—No allowance made for overhead charges, such as interest, insurance, depreciation, etc., which should be added to "G" to give gross costs.

* F-1: The figure of 208,100 kw.-hr. is the net power output, after deductions for excitation and other auxiliaries.

The foregoing data were obtained through the courtesy of Charles E. Teft, chief engineer of both plants and of Robert L. Brunet, Public Service Engineer for the city of Providence, R. I., who is consulting engineer for the Jenckes Spinning Co.

Electric Current Without Cost During Heating Season

An instance of the saving to be realized by generating the necessary current in a building where heat is maintained is found in the New Weston Hotel on the northeast corner of Madison Ave. and 49th St., New York City. Although the generator has been in operation only a short time, the showing at present is that the electric current used for light and elevator service is a cost-free byproduct and will continue so during the heating season at least. Mr. Clayton, the lessee of the building and proprietor of the hotel, feels that with his modern kitchen equipment he will be able to utilize a large percentage, if not all, of the exhaust steam in summer also, because of the diminished use of current for lighting during that period. The new unit is a high-speed self-contained American Ball 50-kw. three-wire direct-current set with an automatic oiling system, so that operating attention is reduced to a minimum. Another unit of the same type but only about 25 kw. capacity will be put in as soon as the manufacturers can deliver it. This small unit will be able to supply the current during the periods of least demand—during the day and the late part of the night. The chief engineer, James Daugherty, is enthusiastic over the showing already made and expects to do still better when the new set is in, which will permit better manipulation or handling of the load.

The building has a frontage of 79½ ft. on Madison Ave. and 85 ft. on 49th St., is 12 stories high and contains 176 guest rooms besides the commodious dining rooms and offices—roughly, 7000 sq.ft. of floor space. It is of modern fireproof brick and steel construction, so that heating it is not difficult, and by the use of high-efficiency lamps the current consumed is comparatively small, making an ideal combination for a private plant, especially since the services of an engineer are essential and no additional help is required whether the generating units are in use or not. Complete operating costs for a year, when available, will furnish material for comparison with past performance when no current was generated.

Notwithstanding the extremely cold weather and the poor quality of the coal he is able to procure, Mr. Clayton's daily reports show no increased coal consumption, while generating all the electric current used about the hotel for illumination and elevator service, over that used when only the heating was being done, so that the electricity generated can be considered as a byproduct.

The calculation regarding the capital invested and the return from it, is interesting. Placing the cost of the first unit at, say, $2500 (which seems ample considering the fact that there was practically no cost for the foundation, switchboard, etc.), and the annual reduction in the cost of service at $620, the difference between $1100, the approximate total cost per year for the street service and the partial street service still retained at a cost of $480 per year, or $40 per month for the minimum. Six per cent. of $2500 = $150 interest to be deducted from $620, leaving $470 to be deducted from $2500 = $2030 remaining at the end of the first year. Continuing the calculation for succeeding years, it would show $1532 at the end of the second, $1004 at the end of the third and $444 at the end of the fourth, so that by the end of the fifth year this unit would have paid for itself.

Taking again the case of the smaller (second) unit, this should not cost more than $1500 and by means of it the street service could be dispensed with, saving $480 per year. Six per cent. of $1500 = $90, which, subtracted from $480, leaves $390 to be deducted from the first cost at the end of the first year, leaving $1110. There would remain $697 at the end of the second year, $259 at the end of the third, and by the end of the fourth year this unit would be paid for by its own output.

Therefore, allowing liberally for insurance, extra taxes, repairs, lubricants and a proportionate fuel charge for that part of the year when the exhaust steam is not all used, the period required for the installation to pay for itself is not extended more than a year or two at most. Or, extending the period of the transaction to 20 years and allowing for a total depreciation in that time, 5 per cent. of the $4000 investment, or $200, would have to be deducted annually from the net saving shown after overhead is taken care of. Then $4000 at 6 per cent. interest and say 1 per cent. for extra taxes and insurance, 7 per cent. in all, from $1100 is ($4000 at 7 per cent. = $280 + $200 refund on principal) $480, leaving $620 net per year. Even setting aside $120 per year for "incidentals" leaves a $500 saving, or 12½ per cent. clear on the original investment.

Low-Pressure Turbines for Lineshaft Drive

By R. J. HORNE

Geared low-pressure steam turbine used to drive a lineshaft in a paper mill resulted in obtaining 600 hp. without any cost for steam and made it possible to operate the plant with eight boilers in service where before the installation of the turbine thirteen boilers were required.

MANY a mill owner whose plant is driven by lineshafts finds, when he seeks to add power supply, that the simplest solution—electric-motor drive supplied from existing power lines—is not available. Often, however, there is sufficient boiler capacity in the plant to do the work if it is effectively applied. Particularly where the lineshaft drives only a small number of machines, an ingenious solution of the problem is to install a turbine, with reduction gearing.

In a western Pennsylvania paper mill there is a unique lineshaft drive consisting of a Westinghouse low-pressure turbine and double-reduction gear, Fig. 1. There are two mainline shafts to which the machines are belted. To one lineshaft are belted two cutters, ten beaters and one jordan; and identical equipment, with the exception of the cutters, is belted to the other shaft. Under ordinary running conditions only seven of the ten beaters on each shaft are in operation at one time, and these, with one jordan, require about 600 hp. The rag cutters take 20 hp. each.

Originally, these two lineshafts were each driven by a noncondensing reciprocating engine. However, one of these engines was wrecked, and it became necessary to obtain some form of drive to replace it.

It is interesting to note the considerations entering into the final selection of the new drive. These conditions were somewhat as follows: Two 100-hp. noncondensing engines turned the rolls and gave practically all the exhaust steam necessary for feed-water heating, so that all the exhaust steam from the 700-hp. noncondensing Corliss engine driving one of the lineshafts would have to be discharged to the atmosphere unless some means were provided for abstracting the energy still available in it. A low-pressure turbine was, without a doubt, the logical prime mover, but it would have been of little use, on account of its high speed, without suitable reduction gearing.

Other types of drive were considered, but each had inherent characteristics which disqualified it; for instance, a duplication of the old reciprocating engine with the inevitable wasting of exhaust steam. A condensing engine would have been expensive and no material improvement. Again, an electric motor, while comparatively cheap to install, would have been much more expensive when the electric-power bill was added to the cost of energy lost in wasted exhaust steam. And finally, it was still more expensive to install a turbine generator and an individual electric drive, because the existing equipment was of an entirely different character. In a new plant where all equipment is being installed for the first time, the individual electric drive is by far the best, for reasons too well known to need discussion here.

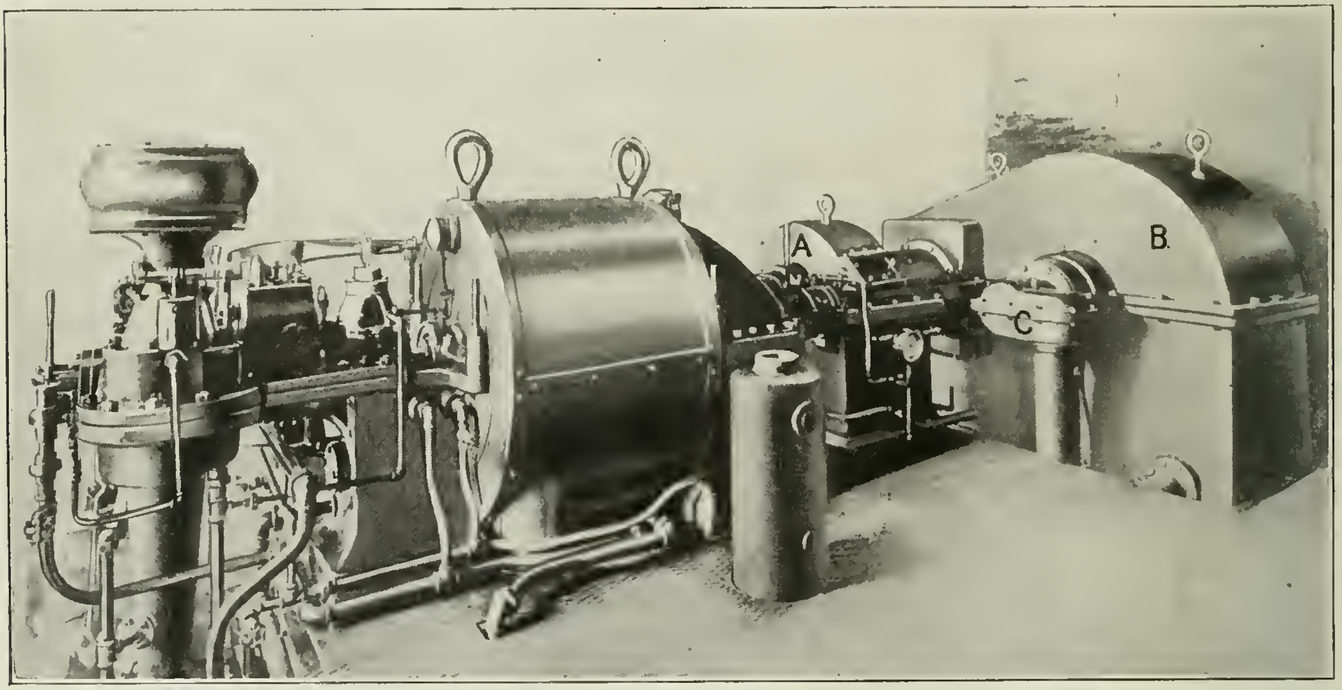

FIG. 1 LOW-PRESSURE STEAM TURBINE WITH DOUBLE-REDUCTION GEARS

A few approximate figures will show more clearly the fitness of the low-pressure turbine for this application. The exhaust steam from the 700-hp. Corliss engine was more than sufficient to give 600 hp. in the low-pressure turbine. The engine takes steam at 150-lb. pressure and exhausts into an oil separator at a back pressure, depending on the load, from 0 to 4 or 6 lb., which is approximately the pressure of admission to the low-pressure turbine. The steam is then expanded in the turbine down to a vacuum corresponding to 27.5 in. of mercury referred to a 30-in. barometer, the vacuum being maintained by a Westinghouse-Leblanc low-level jet condenser and air pump. The pumps are centrifugal and are driven by a small steam turbine through a reduction gear. They take their water from a near-by creek and discharge it from the condenser into a reservoir at an elevation of 45 ft. This water is used in the manufacturing processes. The small turbine runs noncondensing, and its exhaust steam goes to the feed-water heater, so that only a part of the heat energy in the steam used by it can be charged to the turbine, and even that cannot be charged against the main turbine, for it is used to do work in elevating the discharge water from the condenser to the reservoir and should be charged against the total cost of manufacturing. In brief, it may be said that this paper company actually gets 600 hp. without paying a cent for steam and is using just one-half the steam formerly used with two reciprocating engines for the same power.

While this particular mill was not enlarged, it is evident that with a given amount of exhaust steam, either for noncondensing engines or condensing engines run noncondensing, a large increase of power is made available by the installation of a low-pressure turbine. Further evidence of this possibility for expansion is the fact that, in this paper mill, when the two lineshafts were driven by noncondensing reciprocating engines, a battery of 13 boilers was required, whereas now only eight are required for the maximum load.

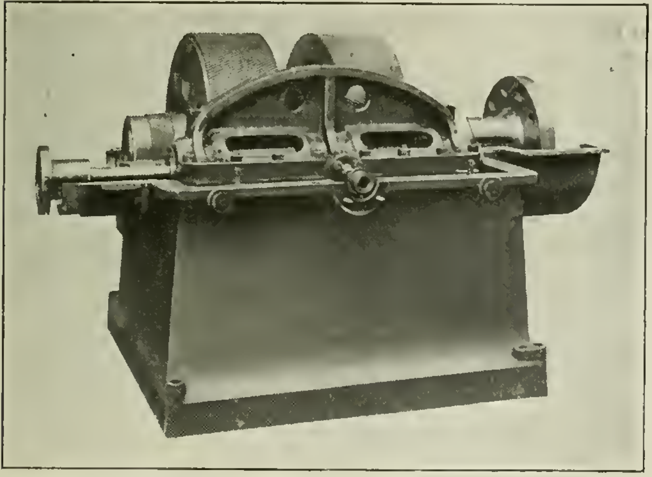

FIG. 2. FLEXIBLE-FRAME GEAR WITH COVER REMOVED

Although the application of the low-pressure turbine is an interesting one, the means of transmitting its high-speed power to a slow-speed lineshaft is fully as interesting and as important. The change in speed is made by means of two reduction gears, shown at *A* and *B*, Fig. 1, because the first cost of a single gear and pinion of ratio 36 to 1 would be prohibitive and the gear would be very large and unwieldly. The first speed reduction, 3600 to 720 r.p.m., is made with a fixed bearing type of reduction gear, the gear shaft of which is direct-connected to the pinion shaft of the second gear, which reduces the speed from 720 to 103 r.p.m.

This larger reduction gear is of the flexible-pinion frame type, known as the Westinghouse I-beam type. In this the pinion is supported on three bearings in a frame, as shown in Figs. 2 and 3. This frame is supported under the middle bearing on an I-beam at right angles to the pinion axle. The flexibility of the web of this I-beam support allows the pinion to tip slightly and to let the teeth of the pinion line up with those of the gear. This lining up is entirely automatic and instantaneous in operation, so that no mechanical complications are encountered and no adjustments from the outside of the gear case are necessary at any time.

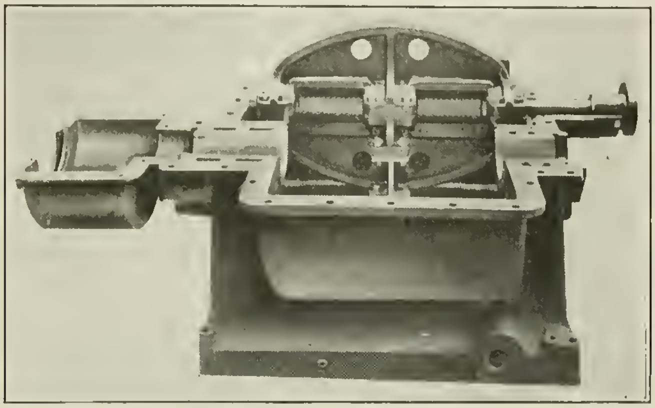

FIG. 3. FLEXIBLE-FRAME GEAR SHOWING HOW THE THREE PINION BEARINGS ARE SUPPORTED

Both reduction gears are lubricated by sprays of oil directed upon the teeth just before they mesh. The oil pressure is maintained by a pump geared to the gear shaft, as shown at *C*, Fig. 1. This pump also supplies oil under pressure to all the bearings in the two reduction gears. For starting, a hand pump is provided which insures a plentiful supply of oil at the bearing and teeth.

It may be asked why a fixed-bearing type of reduction gear was used in one case and an I-beam type in the other. It was a question of tooth pressure which determined the design. Take, for instance, a pinion transmitting 600 hp. at 3600 r.p.m., which was the case of the first reduction gear in the particular installation under discussion. If the same pinion was to turn at 720 r.p.m. and with the same tooth pressure, that is, pounds pressure per inch of tooth face, it would be capable of transmitting one-fifth of 600 hp., or 120 hp., only. It follows, then, that the second gear would have been made five times as large as the first if the same type had been used, and for the transmission of the same amount of power. Such a reduction gear would have been large and bulky. It would also have been costly, because cost is a function of size.

In order, then, to make a reduction gear that would be within reasonable limits as to size, and at the same time marketable, the allowable tooth pressure had to be increased, or in other words, the factor of safety included in the allowable stress in fixed bearing design had to be lowered. But if this were done, some other safety factor would have to be incorporated to insure reliability of operation, otherwise a slight misalignment of the teeth and uneven distribution of tooth pressure would result in a failure of the gear. This safety factor was found in the I-beam support for the pinion, which corrects any misalignment and uneven pressure distribution that might otherwise exist.

In the case of the reduction gear with fixed bearing support for the pinion, misalignment, although practically prevented by good workmanship, will not have disastrous results if it should exist, because of the high factor of safety used in the tooth design.

The actual efficiency of the two gears together is 97 per cent.; that is, only 3 per cent. of the total power transmitted is lost in them. This energy is dissipated in the form of heat and is taken up by the oil, which in turn is cooled by a water-cooling system. As to reliability, in the paper mill under discussion the double reduction gear has run 24 hours per day, six days per week, under maximum load, and it has never been shut down on account of trouble with the gears.

The Cost of Coal

DURING the first few weeks of this year, when the entire country was in the grip of unusually severe winter weather and the railroads were unable to meet the demands made upon them for the transportation of fuel, the price of coal was a matter of secondary importance. The main consideration was the possibility of getting coal, regardless of kind, grade or size, at any price whatever.

Now that moderate weather has decreased the pressing demand for coal and has allowed the railroads to recover somewhat from their congestion, the coal user naturally turns again to a consideration of the cost of his fuel.

The cost of coal to the consumer is the sum of several items, each of which can be reckoned more or less exactly. The first of these is the price of the coal per ton at the mine. This is fixed by the Government, since a definite schedule of rates is set to cover the selling prices of the various kinds and sizes of coal. These prices, per ton f.o.b. at the mines, are given in Tables I and II. They should be increased by the amounts allowed for wage increases, as given in the footnotes to the tables. Also, the reductions allowed during certain months of the year should be taken into account in all cases in which they are applicable.

Since the issuance of the order putting into effect the reduction of 30c. a ton on anthracite for domestic use, the Interstate Commerce Commission has granted the railroads an increase of 15c. a ton on all coal freighted. As a consequence, coal dealers are puzzled to know whether they shall reduce their price 30c. and pay the increased freight of 15c. or whether they shall reduce the price to the consumer only 15c. The Fuel Administration will be asked to decide the matter.

TABLE 1. PRICES OF ANTHRACITE

	Grate	Egg	Stove	No. 4	Pea	Buck.	Slack
Arkansas:							
Bernice district....	$7 30	$7 55	$8 30	$8 30	$6 30	$2.85	$2 50
Spadra district....	6 80	6.80		7 30	4 80		2.50

The foregoing prices are f.o.b. mines and nothing to be added.

All these prices—except those for slack—are subject to the following reductions: 90c. in April, 1918; 75c. in May; 60c. in June; 45c. in July; 30c. in August; 15c. in September.

Pennsylvania:	Broken	Egg	Stove	Chestnut	Pea
White ash	$4 55	$4 45	$4 70	$4 80	$3 40
Red ash	4 75	4 65	4 90	4 90	3 50
Lykens Valley	5.00	4 90	5.30	5 30	3.75

The foregoing prices do not include the 35c. per ton allowance for wage increase under the President's order of Dec. 5, 1917

Beginning Apr. 1, 1918, and continuing to Sept 1, 1918, the prices on all Pennsylvania anthracite for domestic use are subject to a reduction of 30c. per ton

The first schedule of Government prices, which went into effect less than a year ago, covered only such coal as had not been contracted for, or, in other words, free coal. By the first of April of this year, most contracts will have expired, and any further purchases or contracts to purchase will be made on the basis of the new prices. The prices shown in Tables I and II include all changes and modifications up to the fifth of April, 1918.

Jobbers' commissions as separate items of cost have been eliminated; instead, the commission of the jobber is included in the price at the mine, beginning Apr. 1, so that the retail dealer will obtain coal at the same price, whether purchased through a jobber or direct from the mine.

Still another item of cost that may have to be considered in connection with bituminous coal is the allowance for cleanness. According to a ruling of the Fuel Administration, operators who use special means to eliminate impurities from their products will be allowed to add 20c. a ton to the Government prices for coal at the mine. The objects of this concession are to stimulate production and to insure a better quality of coal. The offer embraces the period from Apr. 1 to July 31, 1918, and permits will be extended beyond Aug. 1 in all cases in which such action seems proper. Retail dealers must also obtain permits from the Fuel Administration before they will be allowed to add to their prices the allowance made to the operators. Specially cleaned coal will be designated by cards in the cars in which such coal is loaded and also by notations on the invoices.

The next item is the freight on the shipment. As the freight rates of the various railroads engaged in interstate transportation are subject to the approval of the Interstate Commerce Commission, they can be determined by addressing an inquiry to the commission. Thus, the freight charge per ton of coal from the mine to the destination of the shipment may readily be ascertained.

In many cases the coal must be transported a part of the way by barges or steamers. This is particularly true of the coal consumed in New York City and many parts of New England. Transportation by water adds another charge for lighterage or water freight. In normal times the water haul from New York to Boston is about 50c. a ton, and from Newport News to New England ports it is from 70 to 90c. a ton; but under the stress of a scarcity of coal-carrying bottoms these charges rose to as much as $4 a ton during the recent fuel crisis.

If the coal is purchased through a local dealer, or if the purchaser must pay for hauling the coal from the wharf or railway to his plant, there will be a charge for delivery. The amount of this item is easily and directly obtainable.

After the several items of cost have been determined or estimated, the reasonable total cost of the coal per ton may be found by adding them. The sum will give the consumer a fair idea of what his coal should cost. If the price he is paying is very greatly in excess of the calculated price, he may feel reasonably certain that someone is profiteering at his expense.

TABLE II. PRICES OF BITUMINOUS COAL PER TON F.O.B. AT THE MINES

State	Run of Mine	Prepared Sizes	Slack or Screenings
Alabama:*			
Big Seam district	$2 15	$2 45	$1.85

Fall and Rise of Government Bonds on Account of War

GOVERNMENT bonds, like people, act pretty much like one another under similar conditions. Whether they are French, English, German, Russian, Japanese, American or any other nationality, people will act according to well-established psychological traits, laughing at about the same thing, crying over similar events and manifesting fear under given situations. Corresponding to human temperament, the market value of Government bonds is also subject to well-defined changes, and one of the most consistent similarities of conduct which history shows to be true of them is their habit of temporarily dropping on account of war.

Sometimes they do so to an alarming extent, no matter how stable the government that issued them, no matter how rosy its military situation and no matter how unimpaired the resources behind the securities may be, guaranteeing the prompt payment of their interest and their redemption for full face value at maturity.

But just as consistently as history shows that government bonds go down during the war, no less does it record that their usual habit has been not only to recover to their original price, but also, in many instances, to rise to a marked degree above it after the end of the war.

At the present writing your Liberty Bonds are quoted in the market at about 97. Taken as a detached condition, without regard to history, and looked at simply from the narrow pocketbook point of view, the fact that something you paid $100 for a short time ago will bring you only about $97 at the present moment may seem to be disquieting. But it simply means that United States bonds are now doing what the bonds of all nations do in war time.

Our bonds have depreciated to a lesser degree than most government bonds have done under similar circumstances. One instance may be cited where the bonds of a foreign government went down to almost 50 during a war, but although that nation suffered a crushing defeat and tremendous material losses, within a comparatively few years after the war was ended those same bonds went up to more than 105.

The fact that your $100 Liberty Bond is now selling for about $97 does not in any sense imply a loss of intrinsic value nor uncertainty either as to its principal or interest. It merely implies that because of a complexity of economic factors your Government bond is normally following the way of its historic fellows. Even though Liberty Bonds have thus fluctuated to prices below par, there has been absolutely no fluctuation in the fact that the Government will go on paying the promised interest on them without delay as it falls due, nor in the fact that when the time comes it will redeem them at the full face value regardless of the ups and downs in the market quotations meanwhile.

These ups and downs in the market quotations of government bonds during wars are, in the history of nations, analogous to what the rise and fall of the thermometer is to the weather. Just as you can tell the changes in the temperature by watching the fluctuations in the height of the column of mercury, an expert in finance could almost tell the changes of a country from peace to war merely by looking at the fluctuations in the column of government-bond quotations year by year. He could make a pretty fair guess that the country was at war when bond prices suddenly dropped and fluctuated below the prices of previous years, and then in after years returned to their former levels or higher.

Take the case of Great Britain. Her national debt is funded in the consolidated annuities, or bonds, popularly known as "consols." In 1792 these consols were quoted at 97, but during the Napoleonic wars, 1793-1815, they dropped down to as low as 47¼ in 1798. These consols have fluctuated with England's periods of peace and of war until in 1896 they were quoted at 114. The effect of the present war is shown in the downward quotations of these consols. In 1915 the highest point was 76½ and the low was down to 54, while in 1916 the high was 62¼ and the low 50. In 1917 the high was 56⅜ and the low 51.

The history of the French government bonds, or rentes, shows similar fluctuations on their part. During the Revolution the 5's rentes dropped to 50, and the 3's to 32½. As a result of the Franco-Prussian War, 1870-71, the 3's rentes dropped to 50.35. Although France was defeated, losing Alsace-Lorraine and having to pay a billion-dollar indemnity to Germany, and although there were two funding operations reducing the interest rate, nevertheless the price of France's bonds continued to rise until in 1897 they reached their maximum of 105.25. The present war, true to precedent, has again sent them plunging downward. In 1916 the high was 58 and the low 52.5, and in 1917 the range was 55.5 to 73.25.

Prussian bonds have also felt the full effect of the present war. In 1914 Prussian 4's recorded a high of 86 and a low of 81. In 1915 the high was 65¼, the low 52¾, and in 1916 the high was 58⅛ and the low 50¼.

The United States 4's of 1925, while not showing a very marked decline during the Spanish War, did show a notable rise the year afterward. Their range for 1897 was from a low of 120⅛ to a high of 129½. The year of the war the low price sank to 117¾ and the high during the war period was only 128½. But in 1899 they rebounded sharply, the high for that year being 134½ and the low 128.

Therefore, in their present market quotations below par, United States Liberty Bonds are simply following the trait of their kind as they normally might be expected to do. By the same token, after the war is over, there is no reason to expect otherwise than that they will return to par and then go above par. More than this, in their present comparatively slight depreciation they are showing typical American stability. Instead of falling only two or three points below par, they might have dropped ten or fifteen points without exhibiting a fluctuation as violent as has been shown by the bonds of other less wealthy nations which have finally soared many points above par.

Editorials

Forestalling a Fuel Famine

THE proper period for laying in a supply of coal for the coming winter is the six months now beginning. There is nothing ludicrous in the statement, even though the country stands on the threshold of warm weather. If any individuals are stirred to mirth at the mention of coal and midsummer in the same breath, it is proof that they have failed to profit by the bitter experiences of the winter that is past.

The crisis that gripped the country during the early part of the year was due, in a large measure, to a failure to exercise ordinary prudence and foresight. The country had become so accustomed to living in a hand-to-mouth fashion that this came to be the accepted mode of existence. But the effect of increased fuel consumption due to the war industries had not been taken into account. As a result, the means of supply and distribution that were satisfactory in normal times utterly broke down under the double burden.

Among the many lessons of importance that the war has taught, none is of more consequence than that of our fuel distribution, which touches at the same time the physical comfort and the commercial prosperity of the nation. It has been demonstrated that we cannot wait until the demand has arisen and then expect it to be met instantly. That plan proved a dismal failure.

As a people, we are beginning to extend our vision beyond the tip of our nose, and the range is lengthening rapidly in the light of swiftly moving events. Obviously, the way to avoid a repetition of fuel famine is to accumulate supplies of fuel sufficient to meet necessary requirements at or near the points where they will be needed.

This should be done now, without delay. The placing of orders at this time, with delivery during the summer, will keep the mines working at full capacity, which is highly important. Recent weekly reports have shown alarming drops in coal output, the decrease in some cases being as much as half a million tons. The country needs a definite amount of coal each year, and if the production falls off at one season it must be made up at another; but unfortunately, it may not be possible to speed up production just when the increased demand arises.

Another phase of the matter should be kept in mind. The living expenses of the mine workers go on whether the mines are working or idle. If the orders on hand necessitate continuous operation, the miner can be kept at his job. But if there is a prospect of weeks of part-time work, the miner is going to seek some other kind of labor in which he can earn a steadier—and probably a larger—income. He cannot be blamed if he does. But if the labor at the mines is diverted to other channels, no wiseacre is needed to point out the predicament of the country when the cold weather arrives.

Further than this, the railroads are now in position to deal effectively with the transportation of the coal supply, if it is distributed over the entire summer. The zone system put into effect by the Fuel Administration will reduce the average length of trip, cut out cross-hauling and simplify the whole problem considerably. But all these efforts for the common good will be completely nullified if the public puts off ordering its coal until the first chill winds of October begin to blow. In that direction lies disaster.

Put in your order at once. You need not be perturbed over the thought that you will be accused of hoarding. The Fuel Administration has seen to that. You will be allowed to accumulate all the coal required to meet your normal needs, and no more.

Protect yourself against future discomforts and perform a patriotic service at one and the same time.

Remember the first few weeks of last January.

Put in your coal orders—NOW!

Internal-Combustion Economy

A PRIME condition of high economy in any heat engine is the avoidance of heat waste. This is so obvious in steam-engine practice that it needs no comment, but it is doubtful if, outside of the field of vision of the designing engineer, it is so well recognized in connection with internal-combustion engines. Briefly, all the potential heat of the fuel that is not transformed into work given off at the shaft is wasted. While much of this waste is inevitable, some of it can be avoided. To grasp fully the significance of this factor we should know in just what way heat is wasted. Heat not transformed into mechanical power passes away in the cooling water, in the exhaust and in friction and radiation. The friction of the piston and the bearings passes off in two directions—by direct radiation from the bearings principally, from the piston by conduction through the walls of the cylinder and to some extent by radiation from the interior.

The internal-combustion engineer regards the operation of the engine in two ways—one from the viewpoint of indicated work on the piston and the other from the viewpoint of power delivered to the flywheel. From the viewpoint of indicated work we have the heat of the engine divided into three principal parts—work, jacket loss and exhaust loss. Roughly, the division for the average engine is about even, or one-third to each. Taking the average of tests of gas engines ranging from six to sixty horsepower, the heat distribution runs thirty-eight and three-tenths per cent. in the exhaust gases, twenty-seven and four-tenths per cent. in cooling water and radiation, and thirty-four and three-tenths per cent. indicated work.

The average mechanical efficiency of this same group of engines is about eighty-five per cent. This summary of heat losses gives a goal that the operator should strive to reach or surpass. Both exhaust and jacket losses may be increased by poor adjustment of valves or ignition or other derangement of the function of the cycle. Jacket loss is increased by keeping the jacket cooler than necessary. Excessive friction is a source of loss that should not be tolerated in any well-conducted engine room.

For a Diesel engine the average heat distribution is: Exhaust gases, twenty-three per cent.; cooling water and radiation, thirty-four per cent.; and indicated work, forty-three per cent.

The average mechanical efficiency of the Diesel is seventy-eight per cent. The high friction loss as compared to that of the gas engine is due to the auxiliaries and especially the air compressor for injection. It is interesting to notice that the final efficiencies of the Diesel and a good gas engine of moderately large power are very closely equal. The efficiency, based on the brake-horsepower, of the Diesel seldom exceeds thirty-five per cent., while gas engines of moderate size have shown total efficiencies of thirty-two and five-tenths per cent.

The value of this knowledge to the operator will be appreciated when he realizes the fact that the efficiency of the engine depends upon keeping it in the very best of operating condition at all times. Excess of friction, improper cooling or any derangement of the valve or ignition mechanism is shown promptly in an increased fuel consumption.

Consideration of heat wastes shows the engine designer opportunities for improvement. One of the most promising fields of endeavor appears to be along the line of cutting down the exhaust waste. The method that gives the greatest assurance of improvement is complete expansion. It has been attempted, but there is one serious stumbling block in its path, and that is friction. It is an easy matter to increase the indicated efficiency by expanding beyond the pressure at which the exhaust is released ordinarily; but to offset that gain, there is the increased friction of the engine, which is likely to equal, if it does not exceed, the gain obtained by increased expansion.

Help the Counter-Offensive by Buying Liberty Bonds

THE whole civilized world at this moment of writing is interested in one thing, the counter-offensive. When will it start, how will it fare against the hordes of Hindenburg now engaged in their mighty and ferocious bid for a world decision?

But the great drives of the western front are not affairs of days or weeks. They come after careful preparation; some before this have taken months to run their course. And so with the counter-offensive. It must be deliberately well-timed, and it must have a duration in proportion to the sustained thrust it is designed to defeat.

Both these conditions have been happily fulfilled for our own share in the counter-offensive here at home. Possibly it has never occurred to a great many anxious patriots, scanning the headlines for some confirmation of hope in this critical time, that they have a personal and vital part to take in the effort to halt Hindenburg. This counter-offensive was started on Saturday, April 6, the anniversary of our entrance into this titanic struggle for everything that makes life sweet. It will last a month, following a schedule as carefully mapped out in advance as any the Germans have ever prepared for a march on Paris. Its result, a huge oversubscription to the Third Liberty Loan, will have carried every objective, financial and moral, which it is at present our function to carry in our majestic progress toward victory.

This is not a mere figure of speech which defines our Liberty Loan campaign as a counter-offensive. This is not a war simply of military and naval forces, but of whole nations, of the stay-at-home civilians of either sex and every age as surely and completely as of soldiers and sailors. At home the mobilization of money and industry for the prosecution of war, a process involving every inhabitant of the country when successful, is as vital a part of the vast conflict as the give and take across No Man's Land. With a great national response to this, the Third Liberty Loan, we Americans at home here, from three to six thousand miles from the scarlet waters of the Somme, are launching an offensive against Hindenburg as sure to hit his line as if we were plunging over the top tomorrow with bayonets fixed to attack his shock troops.

Keeping Down the Cost of Coal

THE United States Fuel Administration has adopted strict rules to govern the distribution of coal. Licensed distributors may not serve as middlemen unless their services are bona fide. If it is found that the licensee as purchasing agent has direct or indirect control of the mine owner, no commission will be allowed; or, if the licensee is in position to dictate to the mine owner and prevent him from selling to any consumer or retail dealer who has not employed the licensee as purchasing agent, it will be assumed that there is direct or indirect control. Any licensed distributor who attempts to obtain a purchasing agent's commission unless actually engaged as a purchasing agent will have his license revoked.

The object of this ruling is to give the consumer or retail dealer free choice as to whether he will employ a purchasing agent. Further than this, it is possible that all coal contracts made before April 1, 1918, will be declared void, thus putting the whole coal output on the market at the Government prices.

To public-utilities commissions, petitioned to allow increases of rates on account of the high cost of fuel, we suggest that raises, if allowed, be in the proportion that the increased fuel cost bears to the present price. Of the eight- or ten-cent rate to the small consumer it is a very small proportion; of the one- or two-cent rate to the big user it is a large fraction. There is no reason why the small user should be made to carry more than his share of the increased cost.

The old-fashioned wood engraver was unable to make a picture of a chimney without a picturesque cloud of smoke issuing from it, or of a machine without a man with a tall hat and cane in the foreground. The modern artist is still so possessed of the ideals of a past generation that he cannot depict an engineer without a workingman's cap with a visor on it.

Correspondence

Indexing Trade Literature

Trade pamphlets, circulars, catalogs, etc., are of value to the power-plant engineer and should be preserved; but when the engineer stops to contemplate the large volume that will accumulate in a year, he begins to realize that it is sometimes like hunting for the proverbial "needle in the haystack" to find the particular piece of information that is wanted unless some system of indexing and filing is employed.

Many of the large companies making a variety of articles issue large and expensive general catalogs which contain much information other than listing sizes, etc., and which are of value to the engineer or purchasing agent. Then there are bulletins and pamphlets which are of uniform size and intended to fit suitable binders. But there are many pieces of advertising matter received that are outside the scope of the plant and of only general interest to the engineer. For instance, the chief engineer of a department store using 220-volt direct-current service from his own plant will receive catalogs of, say, a new 150,000-volt transformer or hydro-electric machinery or relating to special street-lighting equipment, which represent considerable expense on the part of the manufacturer.

Many pamphlets, circulars and data sheets are sent out to supersede former issues on the same subject, and are usually so marked but not always. Unless they are marked, the engineer may keep both copies, thereby congesting his filing system and possibly causing confusion by getting the older copy when looking for information. Valuable data are in the many loose sheets which are received from time to time, yet they are difficult to save unless some system is followed.

In the modern manufacturing power plant trade literature on all parts of the plant is essential and, in addition to power-plant machinery, must include a variety of subjects, and the system used to keep these numerous pieces convenient for use will depend on the space available and on the ideas of the engineer.

One of the simplest yet efficient systems that has come to my attention is that of a public institution which receives a large amount of trade literature. In the system formerly employed all the large catalogs were numbered from 100 up, and the smaller pieces sorted out as to subjects as much as possible and placed in file boxes which were numbered beginning with No. 1. The large catalogs were numbered with a sticker on the back and set on the shelves, as were also the file boxes. A card index was then made of the subjects, with the file or catalog number showing just where the desired information could be found. After a few years this system outgrew the available space and a metal file cabinet was installed. This case has seven drawers 16 in. wide, 11 in. high and 24 in. deep. In each drawer there are from four to eight numbered index cards. The large catalogs are listed as before, and the small catalogs, etc., are given a file number beginning with No. 1, and as far as practicable sorted out as to subjects. It is not possible to do this in every case as there are many small catalogs that contain several separate and distinct items. A new card index of this literature was then made, and also another index of firms. If it is desired to find the catalog of a certain firm, it can be quickly done by referring to an index of firms.

The principal advantage of this system is that it is simple and compact. The hundreds of pieces of trade literature are kept where they are easily reached, and after the engineer has used the system for a few months he can, in many cases, find the desired catalog without referring to the index, provided it is replaced where it should be when used. After the system is installed, the work of keeping it up is slight. When a new catalog is received, it is numbered as to subject and an entry made on the proper index cards. About once a year the whole system is gone over, and obsolete and duplicate matter cleaned out. J. C. HAWKINS.

Hyattsville, Md.

Burning Wood To Save Coal

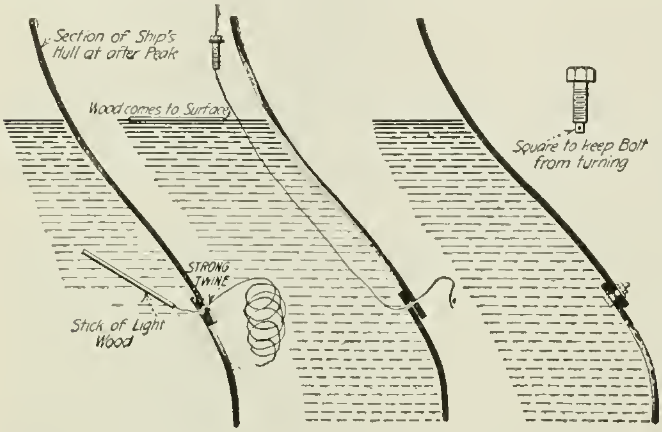
Commenting on G. N. McIlhenny's letter on page 194 in the issue of Feb. 5, I would say that there is no doubt that the substitution of wood for coal is entirely feasible and advisable under present conditions in many Southern plants, especially if good, dry wood is available. Full capacity may be had from almost any coal-burning boiler with dry wood, but not with green wood. Burning green wood entails great waste as a large percentage of the heat in wood is required to dry the wood itself in the furnace. It takes from three months to one year, depending on the kind of wood and climatic conditions, to thoroughly dry wood stacked in the open.

To successfully burn green wood a strong draft is required and a much greater distance between the grate and the boiler than is found in the ordinary coal-burning installation. In firing green wood the furnace should be kept "crammed full," replenished as fast as burned and the intensity of the fire regulated with the damper. I can say, however, from a wealth of experience that there will be few occasions to close the damper when firing green wood; the big worry is to keep steam if there is much of a load on the boiler. The idea of burning or drying the wood in the combustion chamber is no good. Besides the trouble of getting the ashes out, it would be necessary to let the fire die down to a certain extent to allow the fireman to get at the wood in the combustion chamber to drag it back on the grate. No boiler could be fired at half of capacity under these conditions. As to iron bars to protect the blowoff pipe, they might last a week, probably less, in the direct path of the heat under a hard-fired boiler.

Ash Fork, Ariz. W. G. CAMP.

Bolting a Rivet Hole Under Water

The illustration, "Bolting a Hole Under Water," on page 81 in the Jan. 15 issue, suggests that the artist had in mind a situation one may be up against on board a ship, although the necessity of closing a bolt hole under water may arise in connection with open tanks on land. The kink there illustrated, however, does not appear as certain of quick success as the one shown herewith, which is an old catch at marine engineer's examinations.



METHOD OF BOLTING A RIVET HOLE UNDER WATER

The principal points against the first-mentioned method are that with even the slightest current or other disturbance of the water it would be rather difficult to get a hold on the string with the wire hook so as to fish it through the opening, and the idea cannot be used if the opening is at a joint in curved plates, as shown herewith.

However, as a practical expedient, I believe that a pine plug or one made of other wood that will swell greatly when in contact with water has its advantages, at least until such time as the insertion of rivets or bolts becomes conveniently possible. This temporary plugging with wood was once successfully resorted to during my experience as a marine engineer, when two rivets had jumped out of a joint in the ship's hull about 14 or 16 ft. below the water line. The plugs remained securely in place until the next dry-docking the ship underwent, which happened to be soon. Of course we could hardly have stopped the ship for such a comparatively small matter, and besides, as there was quite a sea running, the bolting "kink" would have been pretty hard of execution.

Distant-Load Indicator

The following scheme is used in a system where it is desired to obtain frequent load readings at the office of the central station, the power plant being about a mile and a half away. There is no indicating wattmeter in the plant, but an integrating watt-hour meter measures the total energy supplied to a transmission line.

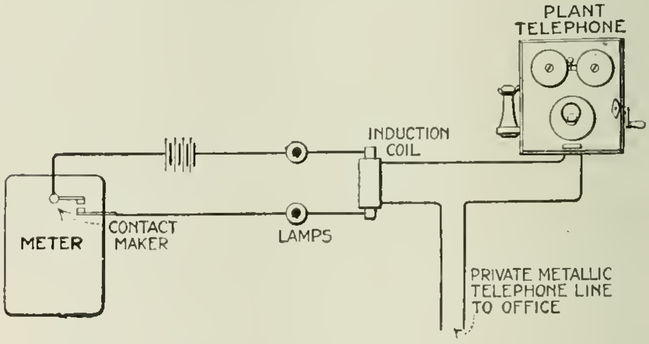
The register of the watt-hour meter was sent to the manufacturer, and a counting or contact-making device applied, which makes momentary contact for a certain number of revolutions of the meter disk. The company maintains a private telephone line between its office and plant, and the indications are transmitted over this line by means of the contact-making device shown in the drawing, wired so that its operation does not interfere with talking on the line at the same time the indications are sent.

Referring to the drawing, it is seen that the telephone line forms the secondary circuit of an induction coil. The primary circuit contains four dry cells and two 60-watt 110-volt type B Mazda lamps, the latter being used merely to act as rheostats to limit the primary current and inserted in each side of the circuit for protection in case the potential or current transformers supplying the meter should break down and subject the telephone line to high voltage, the supposition being that the lamps would either light or burn out in case of trouble.

As a further precaution and also to reduce noise on the telephone line caused by possible leaks in the meter or its transformers, the induction coil is specially constructed, the primary being wound around a core 0.25 in. in diameter, made of No. 18 soft-iron wire and inserted in a glass tube, the secondary coil being wound on the outside of the glass. The induction coil, when finished, is 3.5 in. long and 1.5 in. in diameter. The glass tube was obtained by cutting off a section of a round vial. The coils are wound with No. 30 single cotton-covered wire, there being approximately 2500 turns in the primary and 2000 turns in the secondary.

The primary circuit is closed by the contact-maker in the meter, and this produces a faint though audible click in any receiver of the telephone sets on the line.

The time between two successive clicks is inversely proportional to the load being registered by the meter, and with a stop watch and the following table, the load at the plant may be determined from any station on the private-telephone line:



WIRING DIAGRAM FOR DISTANT-LOAD INDICATOR

Time Between Successive Clicks, Seconds	Kilowatt Load
10.6	100
15.9	75
21.2	50
42.4	25

The complete table used by this company gives the load in kilowatts for every 5 kw. from 5 to 150, and the corresponding time in seconds. The table must, of course, be calculated for the installation it is used on, from the disk constant of the meter, the ratio of the reducing motion on the contact maker and the ratio of the transformers.

R. S. Seese.

Carthage, Tenn.

Heat from the Atmosphere a Substitute for Fuel

Technically, this proposition is known as perpetual motion of the second kind, and is commonly believed to be nothing more than a mere chimera, simply because the idea of its realization seems to be absurd. In the particular branch of science which treats of the motive power of heat, treatment of this idea as chimerical is the fundamental dogma from which is derived the so-called "second law of thermodynamics" and underlies the entire science as it is taught at the present time.

In the year 1824 Sadi Carnot, a noted scientist of France, demonstrated that realization of perpetual motion of the second kind meant the effect of combined action of two distinct heat engines, one acting as a heat pump driven by the other acting as a heat motor; furthermore, that the motor must be operated by a working substance that is more efficient as a medium for converting heat into work than the working substance which is used in the pump to produce a reversed effect.

Carnot stated that realization of this requirement must be impossible simply because its resultant effect would be absurd; and in accord with this assumption he concisely formulated the following principle which bears his name, and is considered the best formulation of that dogma: "The efficiency of a thermodynamic reversible cycle is independent of the working medium." Stripped of all camouflage, this is the real question which the United States Government must settle if it undertakes to investigate the feasibility of obtaining free energy from the atmosphere.

Unfortunately for the cause of the advancement of science, at various times individuals possessed of various degrees of honesty and knowledge of the subject have appeared in the limelight and failed to deliver the goods in regard to this question of free energy. However, it may be said that present-day experimentally derived knowledge of the physical properties of elastic fluids indicates that Carnot's postulate is fallacious; and as a consequence obtainment of free energy from the atmosphere, and in fact from all matter possessed of temperature, is not necessarily impossible.

Milwaukee, Wis. JACOB T. WAINWRIGHT.

Different Rate of Scale Formation

Replying to Mr. Pascoe in the issue of Apr. 9, page 521, I would suggest that the scale formation is greatest on the side of the boiler nearest the soot-blowing openings, because there is less soot on the tubes on that side, therefore the heat transfer is better and more water is evaporated in these tubes; hence the extra scale.

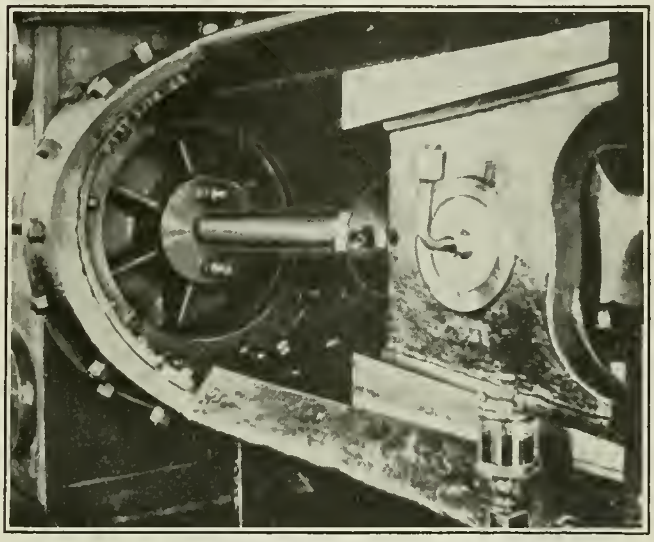
New York City. J. LEWIS.

Corliss Engine Frame Repaired

About three years ago I found that the frame of our 18 x 42-in. Corliss engine was cracked where the flange on the frame is faced to receive the cylinder head. The first method of repair thought of was to have the frame welded, but while many firms would undertake the job none would guarantee it to be a success on account of the strains set up by the process, so I decided to patch the frame with a piece of boiler plate.

As may be seen in the illustration, the recess back of the guides is considerably larger than the bore of the guides themselves. The distance from the end of the guides to the end of the frame is 8 in. and the diameter back of the guides 24½ in. From these dimensions I gave the boilermakers an order to form a cylinder of ⅝-in. boiler plate 24½ in. outside diameter, 8 in. long, with a 4-in. flange turned inward on one end. When the blank came, it was faced on the end that was to be placed against the finished end of the frame under the cylinder nuts, and was then laid out and drilled for the cylinder studs.

The problem then was to get as much of this flanged cylinder in back of the guides as possible. I had decided upon two-thirds of it going in one piece, but exactly how it was to be put in was not fully decided until a friend came in and suggested that I make a galvanized iron templet like the patch and then cut it in two parts in order to ascertain how large a part of it would go in place.



REINFORCEMENT PLATE INSIDE OF ENGINE FRAME

Then the old cylinder studs were all taken out by drilling a ⅜-in. hole, half in the stud and half in the nut, inserting a piece of ⅜-in. round iron to lock them and unscrewing with a 1-in. solid-end wrench. The patch was heated, using charcoal, closed, put in and opened out, or expanded, with bars and jacks, and long tapered wedges were driven between it and the ends of the guides to keep it forced back in place. At first it was thought that rivets would be good to fasten the plate in place, but it was decided that turned bolts ⅞ x 4 in. would be the best with the holes drilled 27/32 in. and reamed to a driving fit for the ⅞-in. bolts. When finished and the cylinder studs put in and drawn up tight, it made a good job.

The drilling was all done with an air motor and the reaming by hand. The total cost of the job was $90, and the engine was out of service five nights. This job was done three years ago and has proved perfectly satisfactory. None of the bolts ever slacked enough to require tightening up at all. J. T. SHARP, JR.

Canton, Miss.

Cook Boiler Explosion at East Chicago

I have read the interesting article on page 382 of the Mar. 12 issue of *Power* on the explosion of a Cook boiler, and the cause of the accident. In a case of this kind all have a right to an opinion as to the cause of the explosion, and I can hardly agree with the deduction as published.

It is stated that the initial fracture occurred in the joint or flange connecting the center tube to the lower tube sheet. It is further expressed in opinion that this type of construction is wrong. Cook boilers have been in operation for about 25 years, and it seems rather a late date to discover an error in construction. Had there been a defect in the design of the boiler, it would have appeared a great many years ago. The illustration, Fig. 2, as published, of the lower drum after the explosion shows the lower tube sheet drawn up into a shape of a bell. This indicates, in my opinion, that the center tube held to the tube sheet and was the last portion to give way. It indicates that this was the final rupture and not the initial rupture. In discussing the explosion of a boiler after it happens, we are prone to criticize the design and give too little attention to the care and management. The statement to the effect that some twenty tubes were renewed just previous to the explosion indicates, in my opinion, the prime reason for the explosion.

The tubes in a boiler of this type which are renewed frequently are those in the front bank facing the fire. In a boiler used for utilizing waste heat these tubes will be renewed several times in 17 years. The repeated rolling will enlarge the tube holes, and the result is that when new tubes are put in, they will not hold if care is not used in rolling. It is my opinion that the new tubes were not properly rolled into the lower drum. They were probably surrounded by other tubes that were warped and consequently pulled out of the lower drum, causing the explosion. It is not unusual for an inspector to find tubes in the lower drum of a boiler of this type improperly rolled. The short drum and the stays make it somewhat difficult for the boilermaker to work in this position, and he is liable to slight the job.

It is also stated that the boiler was fired up from a cold boiler in one hour. This is an unusually short time to fire up any boiler, but I can hardly agree that this particular type is less likely to stand it than any other. The reputation of the Cook boiler was based on its free circulation and quick steaming qualities, and its popularity as a waste heating boiler, and was based on every quality which the report indicates it lacked.

G. W. Cook,
Senior Inspector, Travelers Insurance Co.
Springfield, Mass.

In *Power's* report of the boiler explosion at East Chicago two theories were mentioned as to the cause and each involved unequal expansion, caused no doubt from hard firing. The report says, "One hour before the explosion the boiler had been fired up cold and within this period the pressure had built up to 50 lb.," which in itself explains the primary cause, for no boiler will stand that strain for long.

Engineers and firemen do not fully realize the strain caused by unequal expansion in firing up a cold boiler in two hours or less—something has to give way sooner or later if this practice is kept up. Boilers and settings should be warmed up gradually, and what applies to boilers also applies to steam lines, only with the latter one must be doubly vigilant in order to get rid of the condensation also.

W. H. H. Plowman.
Philadelphia, Penn.

[It is not always possible, in fact, it is often impossible, to determine the exact cause of a boiler explosion, because it is usually so badly demolished. In this instance information has been received to the effect that the lower tube sheet was much thinner at the line of fracture around the center flange. The first impression seemed to be that the thinness was due to corrosion, but it has since been determined that it extended uniformly all the way around at the turn of the flange, and it is the opinion of experts that this thinness is due to the flow of metal at the time of forming the flange. In conversation with William H. Boehm, vice president of the Fidelity and Casualty Co., regarding the subject, the following case was cited as bearing out this opinion. Mr. Boehm said regarding the thinning of the material at the turn of the flange head:

> Several years ago, when a boiler exploded down in Mississippi, we found a similar condition; that is to say, the condition where the drumhead was about ⅛ in. thinner at the turn of the flange than elsewhere. We inspected similar drums in the same plant and found that their drumheads also were thinned by the flanging process. We wrote a little article on the subject at the time, and it is my understanding, mostly on this account alone, that it has been the practice in recent years very greatly to thicken up the heads of drums and tube sheets likely to be thinned by the flanging process.

Mr. Boehm is of the opinion that investigations of such explosions will show that the most likely cause for such accidents is due to this thinning down of the tube sheets by the flanging process, together with the crystallization that has been going on during the period the boiler has been in service. Furthermore, unfortunately, it is not possible, through ordinary means of inspection, to discover a condition of this sort. Even if all the tubes in a boiler have been removed, the thinness of the metal at the turn of the flange would not manifest itself, as the edge of the nozzle and also the edge of the flanged part of the head would show the usual thickness. The best way to make a determination of this sort would be to drill a small hole in the turn of the flange and then to measure the thickness with a short piece of bent wire. Boiler inspectors would hardly resort to such a method and boiler owners would probably not permit the drilling of the head at this point.—Editor.]

Correction Regarding the Use of 85 Per Cent. Magnesia

In my statement, "A Correction Regarding the Use of 85 Per Cent. Magnesia," appearing in *Power*, Apr. 2, 1917, issue, at the top of page 484, lines 2 and 3 read: "a reprint of a report made by the Mellon Institute on heat-insulating materials." This should read: "a report made by Sargent & Lundy on heat-insulating materials."

E. R. Weidlein,
Acting Director,
Mellon Institute of Industrial Research, University of Pittsburgh,

Inquiries of General Interest

Damage from Handhole Cover Dropped in Water-Leg—What damage would result from dropping a handhole cover and leaving it in the water-leg of a locomotive boiler?
A. H. B.

There would be practically no harm done, unless the handhole cover was lodged at or near the bottom of the water-leg in such a position as to cause accumulation of sediment that would endanger the fire sheet to burning.

Shaft Out of Line with Cylinders—If the cylinder center lines of a twin-cylinder hoisting engine are parallel and the shaft center line is ⅜ in. below each cylinder center line, will the difference of level affect the operation of the engine?
H. M. N.

In a hoisting engine of ordinary size, the discrepancy would make no appreciable difference in the wear or operation of the engine.

Pitch Required To Retain Given Percentage of Plate—With rivet holes ¾ in. in diameter, what pitch of rivets would retain 70 per cent. of the solid plate along the pitch line?
A. H.

To have 70 per cent. of the material retained along the pitch line, the material removed for ¾-in. diameter holes would amount to 100 − 70 or 30 per cent., and therefore 100 per cent. of the pitch, or the distance center to center of ¾-in. diameter holes, would need to be ¾ in. ÷ 30 per cent. × 100 per cent. = 2½ inches.

Lap, Lead and Angular Advance—What is meant by the lap and the lead angle and angular advance of an eccentric?
C. B. S.

The lap angle is the angle through which the eccentric must be set more than 90 deg. in advance of the crank to have the valve moved far enough to obtain admission of steam at the beginning of the stroke. The lead angle is the angle through which the eccentric is set in advance of the lap angle to obtain the lead or amount of valve opening at the beginning of the stroke. The sum of the lap and lead angles is called the angular advance of the eccentric.

Apparently Excessive Water Metering—What reasons can be given why the metered water consumption of an office building reported for the month of February should be much in excess of the ordinary monthly consumption? The meter was pronounced correct at the end of the period and there was apparently no unusual use or waste of water.
E. H. H.

Prior to the month in question, the meter may have been "too slow," though it is probable that if pronounced correct at the end of the period, the previous rate of error was not materially different. There may have been a larger supply than usual during this coldest month of the year to make up such wastes as leaving taps open to obtain hot water, or circulation to prevent freezing; or there may have been unobserved wastes of water, as from leaky tank valves or a leaky boiler blowoff valve. Another cause for an apparently higher metering, and one that is largely responsible for popular distrust of meters, is that the final registration charged against the particular month may have been read down closer than usual, thereby including an accumulation of meterings that belonged to a prior period.

Determining Benefits of Aligning Shafting—What methods are employed to determine the benefits derived from lining and leveling shafting of a power plant?
G. H. W.

The benefit of truer alignment in reducing bending stresses will become apparent from reduction in frequency of breakages, less wear and cooler running of bearings from less loss of power from friction, requirement of less lubricant and less vibration of bearings, hangers and other supports. The actual benefit of reduction in power required for overcoming friction must be determined by measuring the power required for driving the shafting before and after it is aligned. For complete information, the improvement should be ascertained with respect to both the bare shaft and with the shaft carrying its regular load. The relative power required by the unloaded shaft will usually be the better index on account of difficulty in obtaining the same load before and after the shaft is lined. For making a comparison, the best method of measuring the power is by means of a transmitting dynamometer, using the same instrument under identical conditions; or by ascertaining the input to an electric motor when used for driving the shafting and whose efficiency has been calibrated for the conditions. Comparable measurements of power may be made with sufficient precision for most practical purposes by carefully indicating the regular driving engine without change of any of its adjustments that would alter the friction of the engine. The diagrams should be made with steady speed of the engine and lowest steam pressure and scale of indicator spring compatible with the load, so as to obtain diagrams that can be measured with greater accuracy.

Obtaining Required Length of Piston Rod—How would dimensions be taken for the length of the piston rod for an engine?
J. E. R.

The important consideration is to provide length suitable for securing equal piston clearance at each end of the stroke. For this purpose, first determine the required finished length from the piston to the crosshead. Having the shaft square with the cylinder center line, and the connecting-rod in place with brasses shimmed to give the average length of connecting-rod, make a mark on the crosshead to register with a mark made on the guide when the crank is on first one dead-center and then the other. The distance between these marks on the crosshead will be the actual length of stroke. Place the piston in the cylinder with a distance piece or pattern of hardwood on the cylinder-head side of the piston, to represent the dimensions of the piston rod with nut or other fastenings that are to project beyond the piston. With the cylinder head in place and piston with distance piece firmly pressed against the head, mark on a wooden rod the distance from the piston at the bore of the piston rod to the outside of the piston-rod stuffing-box, and on the same end of the measuring rod mark the distance from the same part of the stuffing-box to the same part of the piston while it is pressed hard against the crank end of the cylinder.

The difference of distance between the marks thus made on the measuring rod and length of stroke previously laid off on the guide will be the sum of piston clearance distances obtainable for both ends of the stroke. To provide for equal clearances, make a mark on the guide at one-half of this distance, measured toward the crank, from the crank end of the length of stroke previously marked on the guide. After disconnecting the connecting-rod, place the crosshead so the mark previously made on it comes opposite to the mark last made on the guide. Then with the piston hard against the crank end of the cylinder, rod the length for the finished piston rod from the end of the crosshead bore to the end of the bore of the piston. The additional length and dimensions required for machining the ends of the new piston rod will be governed by the design of the piston and crosshead.

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

The Marine Engineer and His Work[*]

By AN EX-MARINE ENGINEER

This is not a technical discussion, but is intended to illustrate by a few experiences, the duties and responsibilities of engineers on board a North Atlantic greyhound.

WE WILL imagine ourselves at the pier in New York, having just arrived in port, and will go below and begin preparations for another voyage. As soon as the telegraph from the bridge rings, "Finished with the engines," all safety valves are raised by the easing gears, the main stop valves are closed and the fires drawn in all but two of the main boilers. As soon as fires are drawn, the water in the boilers is pumped overboard, the manhole doors are taken off, the smokebox doors are hoisted, and the work of withdrawing the retarders, some 6600 of them in number, and cleaning the tubes is begun by the shore gang, numbering about 150 men. By the time the tubes are cleaned, the boilers are cool enough for the men to go on cleaning the furnaces and combustion chambers, and then the work of scaling the boilers is started. We generally found on the furnace crowns a deposit of salty scale ranging from $^{3}/_{32}$ to ⅛ in., each run.

In the meantime the engineers having general supervision of this work are "passing the tubes," which means having a light held at the back end, passing along from tube to tube, and when one is found choked up, chalking it; then in turn inspecting all the furnaces and combustion chambers inside and out, stay-bolts and nuts, tube ends, boiler shells inside and out, all main lines of piping, valves, and in fact every piece of metal visible to the naked eye; withal keeping watch of the boilers under steam. As soon as two boilers can be cleaned and steamed up for the auxiliary service, the two that have been running are taken off and made ready like the others. While the cleaning is going on, a large crew of boilermakers are expanding tube ends, fixing air casings, calking seams which leaked at sea, repairing furnace doors and their catches—which, by the way, is of no small importance, for a steamship's furnace door must stay open until it is closed and stay closed until it is opened; otherwise, with the Howden forced draft, which we had, there will be some severely burned faces as a consequence. The blowing engines are also gone over as carefully as the main engines.

Boilers the Foundation for Good Records

In regard to the care of steamship boilers, or any other boilers under pressure, do not fail to see everything that can be seen, for bear in mind the boilers and their output are the foundation for good records both at sea and on shore.

In the engine rooms in the meantime the work is going on in the following order: Upon receiving the "finished with the engines" signal, the turning gears are connected and two of the most trusted engineers are sent to sound the shafts, this being done by screwing together a sectional sounding-rod about forty feet long, which is carefully machined at each end of each piece and screwed together till it butts metal to metal. This rod, as it is made up in the gloryhole aft (or what would be called the "'tween decks" over the propellers), is passed down through a cupped opening onto the shaft near the propeller bosses and the exact height recorded on these rods after each run. When the shafts are found down or deflected more than a certain prescribed limit, they must be lined up or there will be a repetition of the "Paris" disaster back in the 80's, when the shaft was said to be down 1¾ in. at the point where it failed. Incidentally, one of the senior engineers is liable to happen along at the time the readings are being taken. The circulating pumps on the main condensers are stopped, feed pumps connected by lines of hose to dock hydrants, the exhaust of the auxiliaries put into the auxiliary condenser or to the atmosphere and the steam cut out of all lines of pipe not in use, which means the closing of not less than 30 valves; and the work of overhauling the engines and pumps is now begun by the "shore gang," the ship's crew being off duty with the exception of three or four engineers until the next morning to get at least one full night's sleep or a run on shore—probably the latter.

Work Done in Port

As an example of the work done while in port, my notes taken on board the "St. Paul," when I had charge of her starboard engines, will serve, about the same work going along on the port engines. First entry, "Stripped and examined forward high-pressure piston." This work is done by one of the junior engineers with four or five firemen to assist. We generally found the wear on the piston packing rings in the high-pressure cylinders very severe, due to the high steam temperature, occasional priming which carried over more or less dirt from the boilers, and the very moderate use of cylinder oil, which for these large engines is not over one drop through the lubricator per minute, and frequently no oil at all is used. Sometimes we would find only a few pieces of the packing rings in the piston. This, however, was not a difficult repair, as we always carried spare rings, which were sawed diagonally across and left apart an eighth of an inch when in the cylinder to preclude any chance of cramping. These high-pressure rings are usually the ordinary snap rings called "Ramsbottom," and this same type of packing is used in marine-engine cylinders up to 50-in. in diameter; above that size, light steel springs are used to keep packing rings against the walls of the cylinder. Follower bolts were renewed occasionally as we often found them crystallized to such an extent that, laid across the jaws of a vise, they would break with a very light hand-hammer blow; while when new they could be bent double on themselves without fracture. To make sure that the follower bolts were screwed down tight enough, we generally provided the men with a light steel bar which was to be bent on every bolt in making it up.

"Overhauled piston-rod packing on aft high-pressure rod." "Examined second intermediate piston, found 12 springs broken, replaced with new ones." To do this on a 77-in. cylinder, we had a small manhole in the center of the cylinder cover through which we could enter without taking up the cylinder cover proper.

"Universal couplings on throttle-valve gearing repinned." "Overhauled and adjusted first and second intermediate valve-spindle guides." "Put lighter oil cups on all crossheads." A great fault of oiling service was that heavy cast-brass cups were held in position by light slot-headed screws, which never ought to be used except for holding the cylinder lagging. These cups are better if made of sheet brass and held in place by capscrews.

"Overhauled low-pressure crosshead." To properly overhaul crossheads, we generally had to hang the engine up, take the crosshead brasses off the rod and chip side clearance in the boxes, filing and scraping them before putting them together, for very often we would find the crosshead pins afloat; that is, not bearing in the bottom of the box after the engines had cooled down from a hard run. When we had the crosshead landed in the boxes, after giving the boxes side clearance, we adjusted the amount of running clearance between brass and pin by the use of wire made of pure lead and very soft. This adjustment is made by laying the lead wire across the pin at right angles to its axis and a little short of its half-circumference, one wire about an inch in from each end and one in the center, putting in the liners and putting the top half of the box and binder on and screwing the nuts hard down on the lead wires, marking the nuts before slacking them up so as to have a record of their position. Then, by putting in or taking out liners as required and by taking a final lead impression, we adjusted

---

[*] Informal talk before the graduating class of the Massachusetts Institute of Technology.

these boxes to a clearance amounting to about a thousandth of an inch by micrometer calipers for every inch of diameter of pin or bearing. This method is used for all bearings of marine engines where adjustments are to be made.

"Found piston nut slack on forward circulating engines, and one follower bolt broken." "Reciprocating parts of these engines thoroughly overhauled." "Renewed oil-piping systems on high-pressure valve gear, which was thrown off at sea." "Sawdust connection put on condenser circulating pumps." This was done so that we would be able to inject sawdust into the condensers when leaking. "Air-pump valves and feed-pump valves and seats examined and renewed where necessary." "Filter cloths renewed." "Two copper bends (a practice now abandoned) put into auxiliary steam mains, reducing valves, main to auxiliary thoroughly overhauled, adjusted forward l.-p. crankpin (this adjustment being similar to that of the crosshead, except that we rarely had to give boxes additional side clearance)."

A word about the bedding of the main crankshafts of these ships and about the use of water on hot bearings is probably in order at this point. There is a difference of opinion in regard to the use of salt water on hot bearings. On one new ship we were permitted to use water on the bearings when they were above 110 deg., and this shaft went down uniformly about $\frac{1}{32}$ in. in all its bearings in about twelve months' running. In another, a sister ship, we had orders not to put the sea water on until the thermometers in the bearings (which are hung by wires just clear of the revolving shaft) registered 180 deg., or thereabout, but this shaft went down considerably more and gave a good deal of trouble. It is my practice to keep the temperature down, water or no water.

"Thrust bearing pumped out and refilled with clean oil." Thrust bearings require a great deal of attention and should be closely watched. When they do go wrong, they give a lot of trouble and are hard to handle. "Plates put over two bearings underneath platforms to keep dirt off; hotwell cleaned out." "New water end put in main boiler-feed pump and any number of small jobs too numerous to mention." Boiler-feed pumps on all the ships that I was ever in were about half large enough; technically speaking, they were ample, but in practice we were greatly bothered with them, especially with broken valves, split water ends, broken pistons and piston rods, feed pipes and feed-pipe anchorages, packing blown out of joints, etc. These should have ample margin, so that they can be run slowly.

Washing Down and Painting

On the day before sailing, after all this examination and repair, the washing down and painting is started and the engine rooms are all "slicked up" ready for sea, tools and tackle are all stored away and the boilers closed up and filled with fresh water from the dock. The last half-day before sailing, the ship's engineers are given another short run on shore, sailing hour being at 10 o'clock next morning. At 8 o'clock the night before sailing, the bottom fires in the boilers are lighted under the supervision of one of the senior engineers, who makes it his particular business to see that the water is well up in every one before the fires are lighted and that all the stop valves are opened from the cold boilers; he also sees that the main throttle is "cracked" in order that all the main lines of piping right through to the engine cylinders are warmed up gradually with the boilers. After the fires are started the men of this crew take one turn out of both main engines with the turning gears, first looking the engines over carefully to see that nothing is in the way, that all the small parts are connected, that the crankpits are clear and all is right for running. The turning gears are then disconnected so that, if the engines should move while the cylinders are being warmed, no damage would be done. This is all the trial these engines have before going to sea.

At midnight the high fires are lighted in all the main boilers, Scotch marine type, and the circulating of the water in them commenced. One boiler is taken at a time, and the water is pumped from the bottom of the boiler and back into it again, through the feed pipe, to warm the bottom of the boiler shell and surrounding parts under the fire line of the furnaces, so as to equalize the expansion of the shell. This is a very important part of the process and is under the eye of one of the senior engineers, for a little carelessness might mean the pumping out entirely of one boiler and the flooding of two or three more.

In the meantime the manhole covers in the bottom of the boilers are followed up and every water pocket in all steam mains is carefully drained, for the steam pressure now is 20 or 30 lb. and by 4 or 5 o'clock has reached 100 to 120 lb. The engineer and two assistants go all over the engine department, setting the main valves as they are to be run for the voyage—some of the main stop valves on the boilers are run 2 to 6 turns open, to retard priming where the draft of steam to the engines is heavier than to others. At 8 o'clock in the morning the 8 to 12 watch is detailed below "all hands," and begin filling the oil cups, start the main condensers, prove the telegraph, try the reversing gears and complete the warming up of the cylinders of the main engine, but do not start the main engine.

Getting Under Way

The stokers are given their stations, trim the fires and gradually raise the steam to about 195 lb. Occasionally, at about this time there are little things such as stay-bolt nuts giving way in the combustion chambers or tube ends leaking badly; this means that fires are drawn from the boiler affected and a lot of man-killing work, twelve or fifteen of the shore gang being kept to lend all the assistance they can. Finally, the "all ashore" is sounded and we are left to our own devices and the next thing we hear is "half-speed astern," for the two 10,000-hp. engines, which have each been dismantled in a dozen places and readjusted. Every order of the telegraph is registered in minutes and seconds in writing in a log book. This order is no more than carried out until we have "full speed astern, both engines" to carry us out into the river against the tide. All hands except the chief engineer are below, to assist in getting under way, handling the engine, etc. After a series of "half-speed ahead," "slow ahead," "stop," one side and then the other, we drop the pilot and get the "full-speed ahead" double order, and sometimes if the skipper is feeling extra well, triple order, and the real business of driving a greyhound across the Western ocean begins.

Here is where all the bad work done in port shows up; although every bit of the work was done under the eyes of the engineers, more or less of it had to be intrusted to a gang of machinists who are not engineers and who came aboard ship to get in time. Some of the bearings were adjusted too closely, some improperly put together, so that the first watch at sea between poor firemen and hot engine bearings is often a "hot one." Again, we might leave port without a particle of trouble. In regard to the driving of one of these ships, I wish to say a word about a man's personal character. Above all things, he must be a *man*, say what he means and mean what he says; for in so large a crew of men there are all sorts of dispositions, and in order to get the ship along, a man must have a level head and be more or less a manipulator of men as well as of engines; for if you are not a steam getter, your engineering ability will count for naught. Habitually following one revolution per minute behind the other watches, you will be called up to explain why. Sometimes the men claim to have a poor crew—that's easy; the chances are that the next time you leave port you will have the best watch of men on the ship, or the watch that has made the best time, and then if you fall short, your number may be called. It is a business proposition from start to finish.

On going below to take charge of a watch, the senior engineer will look over the gageboards, see that the reading of the revolution counters for the previous watch are properly recorded at 8 bells. In the meantime his watch of men has gone over the engines to see for themselves that everything is all right. The stoke-hole engineers at the same time have gone through the stoke-holes taking in the average height of the water in the boilers, the amount of coal in front of the boilers and the general condition of things under their supervision. If nothing is reported wrong inside of ten minutes, he will turn to his fellow senior with the words, "I've got her." Should anything be found wrong—for instance, low water in the boilers, hot guide, main bearings, a hot crankpin, eccentric straps, or the like—he may refuse to take the watch until the irregularity is straightened out. Should the water in the boilers be exceptionally short, for instance, he might go on deck till more water is put into the boilers. Or if it were simply a broken-down auxiliary which could be temporarily stopped for repairs, the required number of men would be detailed from the watch being relieved to make the repairs; these men would work for two hours of the watch coming on, when the same number of men would be brought down from the watch coming after—so that any number of men would be liable to be below eight hours on a stretch, for on a "liner" you are with your job all the time.

Troubles Not Always in Engine Room

The following will show that all troubles are not in the engine room. Once, in leaving New York, one of our coaling ports in the ship's side had not been properly secured and just as we were nicely ploughing into a February nor'easter, the door swung open, shipping water in "great shape." It was on my watch and I sent an assistant to tell the chief in person what had happened, thinking it might be necessary to "heave to" or "put the good side to the weather," but I started at once with six men to try to make the door fast between seas. We had no more than reached it when a fire in the dynamo room put the ship in total darkness temporarily. Between getting the door fast, putting oil torches by the side of water-gage glasses and about the engine rooms, we were busy. But after an hour or so we had some of the lights on and made the run without any further trouble.

Another time we were nicely around "the corner" of the Banks of Newfoundland, when a forward port main-bearing stud broke. This was handled about as well as any break of its kind I ever saw. First of all the turning engines were put into gear so that the main engines would not move while we were working over them. We then put a large ring spanner or solid wrench encircling the nut on top of the bearing over the nut; the wrench by the way, weighed about 300 lb., the stud being 6 in. in diameter. This was securely lashed close up to the bearing cap with chains, tightened by a "Spanish windlass" and chain-falls. For additional holding-down power we took one of the cargo-hoisting booms and cut it to reach from the cap to the reversing-shaft bracket, securely lashing top and bottom ends in position. After the turning gear was taken out, we were able to proceed for the rest of the voyage at about half-speed with this engine, occasionally tightening up our rigging.

Shortage of Water Causes Trouble

In regard to the possibility of the boilers being short of water, we were once westward bound, about four days out, running in a heavy beam sea. Through some mistake in a pumping order, two of the ship's trimming tanks were not entirely pumped out, and the ship made one tremendous lurch to port, about 37 deg. from perpendicular, as I remember it, and owing to slack water in the trimming tanks, held there for quite a period—long enough to melt the fusible plugs in five boilers at one time (the fusible plugs being in the side combustion chambers). This meant drawing fires out of forty furnaces (for the boilers were double-enders with four furnaces in each end, half a ton or so of incandescent fuel in each), the closing of the stop valve on each of these boilers and the releasing of the steam through the safety valves by the easing gears before we could get in the combustion chambers to screw brass plugs into the fusible plugs in place of the fusible metal. We accomplished this with a long socket wrench, lying on our backs on planks on top of grate bars which only a few moments before were covered with incandescent coal. You can imagine what this meant. We had sixty men from another watch to help draw the fires and rekindle them, while coal, wheelbarrows, red-hot rakes, slice bars and the like were thrashing from one side of the ship to the other. I have known of fusible plugs being temporarily plugged by very adept men when there was 30 to 40 lb. pressure in the boilers.

Occasionally, in going across we fall in with another ship of our own class going in the same direction. I remember in particular one time when we fell in with the "Campania." We can always tell by the smoke whether it's a ship with anything like our time or not, for if the smoke remains on the horizon an hour she is with us to stay. In coming the other way, we have her nicely abreast in an hour. We sighted the "Campania" astern about 8 o'clock one morning. At 8 o'clock the next morning she was just about abreast, a "stern chase," and at 8 o'clock the following morning her smoke was just in sight ahead, with practically one-third more power than we had, which speaks pretty well for the smaller ship. In the meantime they, in the forecastle, began to take a great interest. The 8 to 12 watch the first morning went below with a full determination to beat all previous records, which they did. The 12 to 4 in taking charge, found stars chalked all around, on the boilers, on wheelbarrows, in coal bunkers and even way up on top of coal piles, showing they had been up there for lump coal, for they certainly did not go up there to sleep. These came off watch with a better record and more stars and more revolutions made per minute. Not to be outdone by any of the other watches, the 4 to 8 went below and made a still better record, which I believe was the highest ever made by that ship before or since. I went forward myself to be sure this watch was properly called, and found them all ready to go below half an hour ahead of time. We had a one-armed fireman on this watch who was born for better work. He had been around the world probably a dozen times, and he said to me: "I heard them 'breaking her up' on the other watches, and I thought I would get the boys ready. She's making such good time I couldn't sleep for her turning." He was my mascot as long as I was in the ship and the boss of the watch in the forecastle. There is another point which I wish to bring out in regard to marine engineering, and which I will illustrate by an incident that happened on board the "New York." We were within twelve or fifteen hours of port when the connecting-rod broke on one of our fan engines, almost wrecking the engine. We could have made the run without this engine, but to go into port with anything broken down was not in our book. The word "helplessness" is not known in the business. The engine was properly repaired, a new spare crankshaft being put in in place of the old one, the frame patched with steel plates, and the engine made as strong as originally, the work being completed about two hours before we reached port.

The Coal Situation in France

Before the war France consumed a total of approximately 65,000,000 tons of coal, of which, in round figures, 41,000,000 tons was of domestic production and 24,000,000 tons was imported from Great Britain, Germany and Belgium. The monthly consumption in peace times thus amounted to 5,400,000 tons. In 1916 the domestic mines produced only 20,000,000 tons and the imported coal amounted to only 19,000,000 tons, making the total quantity available for consumption 39,000,000 tons. In November, 1916, a typical month, the French mines produced 1,800,000 tons of coal and the imports amounted to 1,500,000 tons, the available monthly supply being therefore 3,300,000 tons, which represents a deficit, compared with the monthly consumption in 1913, of approximately 40 per cent. It should be noted, however, that the average for 1913 includes also the summer months, whereas the consumption is necessarily greater in the winter months. The figures for December, 1916, compared with the monthly average of 1913, indicate a diminution of 44 per cent.

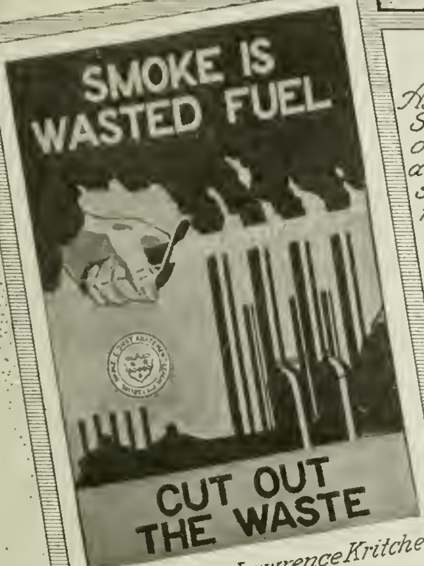
The most hopeful sign, pointing to the unlikelihood of a serious coal crisis during the remainder of the present winter, is furnished by the great increase in the domestic production of coal. In October, 1915, the French mines produced 1,700,000 tons; in October, 1916, 1,800,000 tons; in October, 1917, 2,782,000 tons. In November, 1915, the French coal mines produced 1,500,000 tons; in November, 1916, 1,600,000 tons; and in November, 1917, 2,690,000 tons, or an increase of about 80 per cent. in the two years. It should, of course, be noted that the invaded portions of France contain the principal French coal mines, and that therefore the war has cut off the chief source of supply and has made necessary the more intensive exploitation of the mines in the uninvaded regions.—*Commerce Reports.*

As announced in Power of February 5, the Smoke and Dust Abatement League of Pittsburgh in February conducted a competition to secure poster designs showing the relation of smoke abatement to fuel conservation.

Prizes were offered as follows: First prize, $50; second prize, $20; two prizes, $5; four prizes, $2.50; ten prizes, $1.

The winner of the first prize was Lawrence Kritcher, a first-year student at the School of Applied Design, Carnegie Institute of Technology.

Reproductions of seven of the prize-winning designs are shown on this page.



First Prize – Lawrence Kritcher

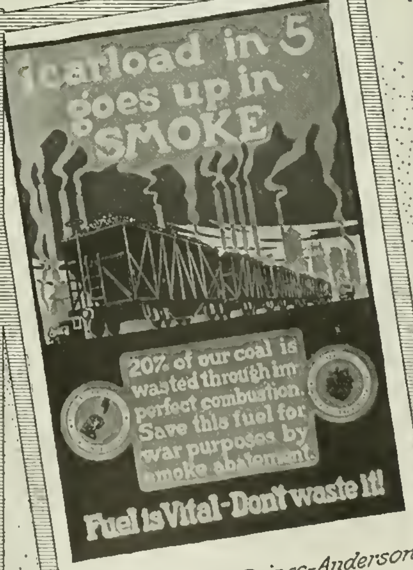
Second Prize - Lloyd Weninger

One of the Fourth Prizes - Mildred Floyd

One of the Fifth Prizes - Winifred Cramp

One of the Fifth Prizes - Hilda M. Kaji

One of the Fifth Prizes - Helen Barkhurst



One of the Fifth Prizes - Anderson

War Service of the Petroleum Industry*

By M. L. Requa

Director, Oil Division United States Fuel Administration

This war cannot be won without an ample supply of petroleum products. We must have, if we are to succeed, not only fuel oil, but gasoline, kerosene and lubricants as well; for them there are no known substitutes.

It is not possible to single out any one product and say of it, this is the most important for the winning of the war. We may say truly that the most important element is the spirit of the soul of the people, the morale of the nation, but in dealing with our industrial life we have absolute need of many things. Food we must have, or perish; steel, copper, chemicals, petroleum—we have need for all of these, and more, or we must suffer defeat. From the standpoint of the winning of the war, not one of these products is more important than petroleum. It lubricates the machinery of our transportation and manufacturing, it plows our fields, drives our vessels at sea and gives life to the airplane that watches over our soldiers and sailors.

As the application of steam and electricity grew, so grew the demand for more and better petroleum products. One to a large degree kept pace with the other. The original "puffing Billy" has grown into the Mallet compound of today; the original "Robert Fulton," wending laborious way down the placid Hudson, into the monster turbine-driven battleship. All these machines have been dependent upon lubrication, upon petroleum; and the more recent advances in marine construction have been predicated upon the use of fuel oil as the means of steam generation.

Rapid Rise of Internal-Combustion Engine

We have witnessed in the last decade the rise of the internal-combustion engine. Its profound effect on rural as well as urban life grows more and more manifest; it competes with the locomotive and the trolley as a means of rapid transit; and as a method of distributing freight in cities, plowing fields, and providing healthful recreation it is rapidly superseding the horse. As an instrument of war it is of paramount necessity; driving the swift-flying airplane that serves as the aërial scout to our armies; it makes possible observations for lack of which disaster would be the inevitable portion of our forces.

In the realm of the internal-combustion engine, petroleum reigns supreme. It supplies the motive power; it lubricates the machinery; it is, in short, the life fluid without which neither motor vehicle nor airplane could serve the needs of humanity.

The internal-combustion engine has created a demand for gasoline of hitherto undreamed-of proportions; it has made what was once considered almost a waste product into the most important element derived from petroleum distillation. Inability to supply the rising demand by recognized methods of refining has spurred inventive genius to new efforts, until today we have the new practice of pressure distillation with its resultant increase in gasoline output.

And what are our assets, with which to meet the demands which may be made upon us for petroleum? What is the strength of this young giant that responds to the nation's call to arms? We have produced from the year 1859 to date a total of more than 4,250,000,000 bbl. of oil. Our production has increased, by decades, from 500,000 in 1860 to 5,260,000 in 1870, 26,286,000 in 1880; 45,823,000 in 1890, 63,620,000 in 1900, 209,557,000 in 1910, and 330,000,000 in 1917. Over long periods the average increase has been about 7 per cent. of the previous year's production. At this rate of increase we shall require 460,000,000 bbl. per annum in 1927; and for 1918, if the average holds good, we shall require an additional amount above last year's production of approximately 23,000,000 bbl. It will be forthcoming, of course; from the known fields, if necessary; and perhaps in part from new discoveries.

We are beginning to realize, however, that our resources are not limitless. It is the consensus of opinion that the Appalachian, Lima (Indiana) and Illionis fields can add little in the way of increased production; leaving but three great known fields to meet our future requirements—Mid-Continent, Gulf and California.

The changes in the industry are startling; today a flow of oil, tomorrow a famine. Spindletop was discovered in 1901, and yet today the Southern Pacific brings oil from Mexico to supply its locomotives plying in Texas. We are confronted with constantly mounting consumption and a constantly increasing percentage of exhaustion. Some day the lines must cross, production will no longer be able to keep pace with consumption and we must seek other sources of supply.

Exact Extent of Future Supplies Unknown

Any mathematically exact estimate of the petroleum yet to be extracted from the rock formations of the United States is, of course, impossible. Undeveloped areas now unknown may add greatly to present estimates. Speaking broadly, however, I think I am safe in saying that it is our duty to conserve most carefully our remaining stores. Locked in the earth, they are of course valueless. Do not misunderstand me or imagine that I am arguing against production, against wildcatting, against the individual effort having for its incentive an adequate reward. I believe all these things must be done. But I am also of the belief that increasingly efficient methods of combustion, lubrication and general conservation will materially alter practices that can be safely characterized as wasteful.

In viewing the petroleum industry from the Governmental standpoint, it necessarily means the viewpoint of national welfare in contradistinction to individual gain; it means the wise husbanding of our available resources so that they may last the greatest time, in contradistinction to producing the greatest quantity in the least time and converting into money the treasures of nature's storehouse.

With the exhaustion of our oil or its advance in price we have, of course, the alternative of producing oil from shale. That there are enormous areas of such shales in the United States is well known among geologists and others who have taken the pains to investigate. These shales will undoubtedly in time be mined for oil, but we must remember that to produce a quantity of oil equal to our present production we shall have to mine a daily tonnage of shale in excess of the tonnage of coal now mined daily. The magnitude of such an undertaking is obvious. It will not be the growth of a day, but of years. And it is likely that because of plentiful supplies of oil which may be brought to the United States by water—cheap oil from Mexico and Central America—it will be many years before these shales are utilized.

Present Necessities Call for Economic Discipline

The stern necessity that has imposed unparalleled economic discipline upon the people of Europe will not disappear or be forgotten with the coming of peace.

This is no time to quibble over technicalities, no time to debate the power of the Government to perform any proposed act. We are at war. The life of the nation is at stake. The preservation of our national existence is of such paramount importance that nothing else really matters, compared with that duty.

Each month during the war the priority demands of the Government will become more and more insistent, the duty of the citizen to supply those demands more and more clearly defined.

If zonal distribution of petroleum products is necessary to supply national needs, zonal distribution will be accomplished. If pooling of tank cars and ships will more efficiently meet national demands, those facilities will be pooled. If well-drilling supplies must be allocated to produce the greatest quantity of oil to meet the increasing demands for oil, well-drilling supplies will be allocated. If licensing of jobbers and others is necessary, they will be licensed. If the petroleum industry or any part of it is so unwise as to engage in profiteering, ways and means will be found to correct that condition. In short, whatever the national needs may be, everything that is necessary will be done to meet those requirements.

---

*From an address delivered at the Petroleum Congress, Chicago Ill., Mar. 29, 1918.

Twenty-Million-Dollar Power Extensions Urged

Recommending extensive hydro-electric development in the southern part of California at an expenditure of $20,000,000 within the next two years, to meet the increasing demands for power and light and for the conservation of fuel, the Railroad Commission of California has issued a decision in its investigation of the construction and operation of electric utilities during the emergency created by the war.

Specificially, the commission recommends that the Southern California Edison Co. take immediate steps for the carrying out of a comprehensive plan for the financing of approximately $15,000,000 for building power plants, that the Southern Sierras Power Co. construct its Rush Creek Bishop line, and the San Joaquin Light and Power Corp. insure the building of additional plants for the increase of facilities, or by purchase agreement, the maintaining of an adequate power supply for agricultural and industrial needs.

The Railroad Commission's investigation was state-wide, but the present decision deals only with the territory south of Merced, the northern part of the state to be considered later. The decision says that though considerable economy of oil would result from more complete interconnection and coöperation of hydro-electric plants, yet the war emergency demands that the corporations take immediate steps to build additional power plants to meet the constantly growing needs for power made by normal increase of manufacturing and agriculture and the special needs of war industries which are rapidly multiplying in California.

The southern part of the state, which is considered in the commission's recommendations, comprises that portion of the San Joaquin Valley south of Merced and served by the San Joaquin Light and Power Corp. and the Mt. Whitney Power and Electric Co., and southern California, which is served by the Southern California Edison Co., the Southern Sierras Power Co., the San Diego Consolidated Gas and Electric Co., the Los Angeles Gas and Electric Corp. and the City of Los Angeles.

The power produced by these companies in 1915 was approximately 930,000,000 kw.-hr., in 1916, 1,010,000,000 kw.-hr. and in 1917, 1,146,000,000 kw.-hr. Of this last amount 911,000,000 kw-hr. was produced by hydro-electric plants, the remainder by steam, requiring a total oil and gas consumption equivalent to 1,316,000 bbl. of oil. It is estimated that the growth in business due to the normal developments and the special war industries will approximate 140,000,000 kw.-hr. per year, and a requirement of plant capacity of about 25,000 kw. and then, in order to keep down the oil consumption of electric utilities to that existing in 1917, will require that amount of development each year.

Economical Effects of Interconnection

The report shows that considerable economy will result from the interconnections now existing and those contemplated by the companies, but even with that saving it will be necessary to increase the hydro-electric facilities at least 20,000 kw. of useful capacity a year, and increase the energy output approximately 140,000,000 kw.-hr. under ordinary rainfall conditions. Consideration was given to the City of Los Angeles existing and proposed developments in connection with the aqueduct, where it appears that at a cost of between $2,500,000 and $3,000,000 the city would produce an additional peak capacity of 36,000 kw.-hr. and an output of at least 150,000,000 kw.hr. a year, resulting in a reduction of oil consumption of 600,000 bbl. a year.

The commission states that the development by the city would be largely completed within twelve months if priority orders were obtained for equipment, but that difficulties exist which apparently make it impossible at this time to count on the development of the plant. These difficulties arose from the fact that the City of Los Angeles contends that it cannot utilize bonds already authorized for the development of hydro-electric plants, but that this money must be used for the construction of distribution systems. The city believes that if a satisfactory agreement could be entered into with the Los Angeles Gas and Electric Corp. whereby that company would lease to the city its entire system, such agreement to contain an option for purchase by the city, the money authorized would be used for hydro-electric plants.

The Los Angeles Gas and Electric Corp., however, declines to consider the plan, which it contends constitutes a complete surrender of the possession of its distribution system to a competitor, and also that its trust-deed provisions make such a plan a legal impossibility.

The commission states that special pains were taken to attempt a solution of the problem, but that failure attended such efforts. It says that it has no authority or desire to order the city to develop the plants or deliver the power to the Los Angeles Gas and Electric Corp., nor authority to compel the Los Angeles Gas and Electric Corp. to accede to the proposition of the city.

The commission states: "It is to be seriously regretted that at this critical period, when conservation of fuel oil is one of the most important war needs, the give-and-take spirit should not be more in evidence and that all interests are not subordinated to actual war necessity."

Reported Power Possibilities

The commission discusses the reported power possibilities of the Southern California Edison Co., the San Joaquin Light and Power Corp., and the Southern Sierras Power Co., stating that the Southern Sierras Power Co. has two possible developments amounting to 17,500 kw. capacity in Mono and Inyo Counties which might be developed, but upon which sufficient funds are not available. It also states that the San Joaquin Light and Power Corp. has certain small developments that are being installed, but that definite information on any large developments has not been presented at this time. It urges, however, that the corporation give serious consideration to adding to its plants so as to meet requirements on its own system.

The Railroad Commission has authorized the San Joaquin Light and Power Corp. to issue $767,000 six per cent. first and refunding bonds payable in 1950. The money is needed, says the company, to buy property, construct, expand and improve its service and facilities.

The Sierra and San Francisco Power Co. has filed with the Railroad Commission an application for authority to issue $1,000,000 of its first-mortgage 5 per cent. bonds, the proceeds to be used for the construction of additional hydro-electric plant capacity on the middle fork of the Stanislaus River, the construction of storage reservoirs on the middle or south fork of that river, and the construction of additional flumes, ditches, etc.

The Mt. Whitney Power and Electric Co. has asked for approval of the Railroad Commission of a plan under which applicants for power will be required to advance a part of the cost of building the lines necessary to serve those making the application. The company states in its application that it will have to expend during 1918 upon its system $108,000 and that in addition to this sum it will have to spend $216,000 for the construction of extensions to care for new consumers, which the company estimates will be in the neighborhood of 4000 during 1918. The greater part of the new consumers will require power for agricultural purposes in the Counties of Kern, Kings and Tulare. The company is in doubt whether it will be able to dispose of its stock and bonds and says that it will have only approximately $600,000 available for the construction of extensions and consequently it is asking those seeking service to bear a portion of the expense of installation.

The Southern Sierras Power Co. has joined with the Corona Gas and Electric Co., the Bishop Light and Power Co., the Rialto Light, Power and Water Co. and the Coachella Valley Ice and Electric Co. for authority for the last-named four companies to sell their plants to the Southern Sierras Power Co.

The prices for these are respectively: $135,914; $60,576; $24,915 and $821,687.

Said B. T. Yew to C. O'Two,
"I work best when I work with you."
Said C. O'Two to B. T. Yew,
"When we are scarce the steam is, too."—*Fecony*.

All After Higher Rates

Electric light and power companies throughout the country are doing their best to obtain a higher rate—not, it is believed, that they are operating at a loss below actual operating expenses, but because they require a greater revenue in order to maintain their profits at about pre-war percentages. In many cases the demand for increased revenue has been granted in whole or in part by the public service commissions; in others the courts have refused increase, and other demands are still to be decided; franchises with "during the period of the war" charges, permitting of an increased rate, are declined, and others hold that contracts are mere "scraps of paper."

Recently, an electric-light franchise was granted to the Arkansas Light and Power Co., by the City of Clarendon, Ark. This franchise carried a 15 per cent. advance for the period of the war over the previous rate. It was rejected by the company for the reason, it is said, that the rate was not high enough on account of the advanced prices of materials and the cost of operating the plant.

Coming further east, the Cleveland Railway Co., Cleveland, Ohio, was not satisfied with existing rates and contemplated increasing trolley fares on Apr. 1. But this was not to be, as it is understood that Common Pleas Judge Pearson has granted the city an injunction restraining the railway company from increasing car fare as it had planned. Judge Pearson ordered the company to arbitrate with the city the necessity for an increase of fare. The increase the company sought to make called for a four-cent fare, seven tickets for a quarter, with the penny transfer charge rebated. The present fare is four cents, six tickets for twenty cents, and a penny charge for a transfer.

Journeying still further east, the transportation companies of New York City are desirous of a six-cent fare. Although the Cleveland Co. wants to charge but a four-cent fare and sell six tickets for twenty cents, New Yorkers have never even had a chance to purchase tickets at reduced rates. If one city can operate street cars for a four-cent fare, why cannot another is the question that many are asking.

When it comes to living up to contracts, some companies evidently look upon them as mere scraps of paper. For instance, the Public Service Corporation of New Jersey has a fight on its hands with the Manufacturers Council of the state. The council, representing hundreds of manufacturers throughout the state, contends that the abrogation of power contracts entered into by the corporation with numerous manufacturers is clearly illegal and that the corporation's notice to many consumers of the cancellation of these contracts is therefore without force.

The Public Service Corp., it will be remembered, canceled its contracts for power last winter when the coal shortage became so acute that it was almost impossible to generate electricity. There was no dissension heard then, and it was assumed that the manufacturers were willing to comply. The council's action furnished the first inkling that there was any objection.

It will be the aim of the council to take concerted action in behalf of those manufacturers who feel that they are aggrieved and who have been compelled, in order to insure a continuance of the power necessary for operating their plants, to submit to greatly increased rates.

Liberty Loan Committee for Machinery and Machine Tool Trades

A special Liberty Loan Committee for the machinery and machine-tool trades has been organized, with headquarters at 334 Fourth Avenue, New York City. The full personnel of the committee follows:

J. W. Lane, chairman, President, E. W. Bliss Co.; R. L. Patterson, vice-chairman, Pres. American Machine & Foundry Co.; Charles B. Houston, secretary, E. W. Bliss Co.; Norman Dodge, director of speakers, Vice-Pres. Mergenthaler Linotype Co.; Charles A. Hirschberg, publicity director, Publicity Mgr. Ingersoll-Rand Co. Committee: M. H. Avram, Slocum, Avram & Slocum; L. Barron, Sec. De La Vergne Machine Co.; Leigh Best, Vice-Pres. American Locomotive Co.; R. K. Blanchard, Neptune Meter Co.; G. D. Branston, Treas. Manning, Maxwell & Moore; Arthur W. Buttenheim, Pres. McKiernan-Terry Drill Co.; W. L. Callister, W. L. & J. T. Callister; De Courcey Cleveland, Pres. Central Foundry Co.; C. Philip Coleman, Pres. Worthington Pump & Mach. Corp.; C. I. Cornell, Treas. Pratt & Whitney Corp.; F. W. H. Crane, Pres. R. Hoe & Co.; J. J. Cuehler, Pres. Columbia Mach. W. & M. Iron Co.; C. G. Curtis, Pres. Curtis Turbine Co.; A. Davis, Pres. Davis-Bournonville Co.; F. S. De Lano, Treas. American Car & Foundry Co.; H. H. Doehler, Pres. Doehler Die Casting Co.; George Doubleday, Pres. Ingersoll-Rand Co.; F. F. Fitzpatrick, Pres. Railway Steel Spring Co.; Henry Fuller, Vice-Pres. Fairbanks-Morse Co.; P. H. Gill, Pres. P. H. Gill & Sons; R. E. Gilmore, Gen. Mgr. Sperry Gyroscope Co.; D. H. Haynes, Treas. American Machine & Foundry Co.; J. H. Hayward, Treasurer Hayward Co.; W. T. Hunter, Sec. A. Schrader's Son, Inc.; Isaac B. Johnson, Pres. Isaac G. Johnson & Co.; J. C. Kelly, Pres. National Meter Co.; W. P. Kethart, Sec. H. D. Berner & Winterbauer Co.; Hy. C. Knox, Treas. American Brake Shoe & Foundry Co.; John Lidgerwood, Pres. Lidgerwood Mfg. Co.; T. Frank Manville, Pres. H. W. Johns-Manville Co.; T. J. Menten, Vice-Pres. Schaeffer & Budenberg Mfg. Co.; Edward T. Morse, Sec. & Gen. Mgr. Morse Dry Dock & Repair Co.; C. E. Murray, Pres. Metropolitan Engineering Co.; Henry Prentiss, Pres. Prentiss Tool & Supply Co.; Joseph T. Ryerson, De Mant Tool & Machine Co.; E. A. Stillman, Pres. Watson-Stillman Co.; H. R. Swartz, Pres. Intertype Corp.; Charles Taylor, Clark, Dodge & Co.; Herbert G. Thomson, Pres. Anchor Post Iron Works; J. M. Turner, Pres. General Acoustic Co.; J. H. Walbridge, Pres. Lalance & Grosjean Mfg. Co.; J. Harvey Williams, Pres. J. H. Williams & Co.; J. B. Wing, Treas. Dexter Folder Co.

Progress of the Public Service Commission's Rate Hearing

Further evidence to show the economy of the isolated plant for combined lighting and heating was given on Apr. 8 at the resumed hearing before the Public Service Commission for the First District of New York. This evidence was based on the records of the steam plant in the Fifth Avenue Building, of which David Larkin is chief engineer.

According to the testimony of Mr. Larkin, the building occupies a plot approximately 236 ft. by 286 ft. and contains about 540,000 sq.ft. of floor space. It is mainly an office building, but the ground floor is occupied by stores and restaurants; in addition, the Aldine Club is located in the building. The service demanded of the plant is the furnishing of electric current for lighting and steam for heating, as well as the necessity of supplying live steam at a pressure of 40 lb. per sq.in. to the Aldine Club and the restaurants all the year round.

The relative costs of operation by private plant alone and by a combination of Edison service and private plant were determined from the records of the plant for the years 1916 and 1917. For 1916 the balance was $26,000 in favor of the private plant, and for 1917 it was $17,000 in favor of the private plant. In other words, these amounts show the additional costs that would have been incurred if the current for lighting had been purchased from the Edison company and the private plant had been used merely to furnish the steam required for heating and for the use of the restaurants and the Aldine Club.

As to the actual saving of coal, the figures were likewise in favor of the operation of the isolated plant alone. In 1916, which was considered an average year, the saving was estimated at 300 tons over that which would be required by combined Edison service and private-plant operation. In arriving at this result, it was assumed that the central station would burn 3 lb. of coal per kilowatt-hour delivered to the customer.

At the conclusion of Mr. Larkin's testimony, the hearing was adjourned until Apr. 29.

The French and British have nobly stood behind their governments in war loans. Where do you stand?

New Publications

STEAM TABLES FOR CONDENSER WORK

The Wheeler Condenser and Engineering Co., Carteret, N. J., announces that the fourth edition of its steam-table handbook is off the press, making a total of 20,000 copies. One reason why this handbook has met with such success is that the pressures below atmosphere are expressed in inches of mercury referred to a 30-in. barometer. Another is that it is complete. It includes a discussion of the mercury column, the errors in such measurements, and constants for their correction. A complimentary copy will be furnished on request to those in responsible positions who are not yet provided with a copy and who deal with steam and its many problems.

Personals

Henry D. Jackson, formerly of Timothy W. Sprague and Henry D. Jackson, consulting engineers, 88 Broad St., Boston, Mass., has joined the organization of Monks & Johnson, engineers and architects, 78 Devonshire St., Boston, as power engineer, taking charge of their power-plant and heating work.

R. W. Spofford, general manager of the Augusta-Aiken Railway and Electric Corporation, Augusta, Ga., who is a retired officer of the United States Navy, has been called to active service. W. C. Callaghan succeeds him as general manager. Mr. Callaghan has been with the J. G. White Management organization, New York City, the operators of the Augusta company, since 1913.

Engineering Affairs

The American Association of Engineers and the Committee on Engineering Co-operation will hold a joint annual meeting at the City Club, Chicago, on May 14. All technical societies are invited to send one or more delegates to this meeting.

Miscellaneous News

A Peculiar Flywheel Accident—In a rolling mill a number of circular billets were piled up in line with the pit of a 30-ft. flywheel. The removal of one of the billets in the lower row set the others to rolling. One of them rolled into the wheel pit and completely wrecked the large flywheel.

A Mortgage Has Been Filed in the office of the county clerk, Eugene, Ore., and executed by the Mountain States Power Co. in favor of the Illinois Trust and Savings Co., of Chicago. The amount of the bonds covered by the trust mortgage is $2,353,000 of an authorized issue of $15,000,000. The Mountain States Power Co. is the reorganized Northern Idaho and Montana Power Co. which operates it. The property covered by the mortgage is that located in various counties of Oregon and used by the Oregon Power Co.

Electric Service for Camp Perry—The Northwestern Ohio Railway and Power Co. will furnish electric service for Camp Perry. The later news with reference to the camp indicates that it is to be a cantonment capable of accommodating approximately 9000 soldiers who will be trained in target practice, both artillery and short-range rifle shooting, with moving targets. It is also to be used as an aviation training ground. Options have been taken on about 1600 acres in addition to the land already used for camp purposes.

The Municipal Civil Service Commission has announced an examination for mechanical draftsmen (electrical), Grade C (male and female), for which applications will be received at Room 1400, Municipal Building, Manhattan, until Apr. 25, at 4 p. m. Subjects and weights: Experience, 2; technical, 6; mathematics, 2. Candidates must be 21 years of age or over, must be citizens of the United States and residents of New York State; will be required to prepare drawings and to do other related work, such as computing, compiling data and plotting in connection with electrical installations for power and lighting. Applicants should have training and experience as a mechanical draftsman such as to qualify them for the position. They must have had actual experience in laying out, computing, drafting or other related work incident to the construction or operation of light and power or similar experience. They should have a good knowledge of the Electrical Code. Salary from $1200 to $1800 per annum.

Business Items

H. W. Johns-Manville Co.'s Youngstown (Ohio) office is now located at No. 520 Market St.

The Homestead Valve Manufacturing Co., of Homestead, Penn., has opened a branch office at No. 1 Franklin St., New York City.

The Brown Instrument Co., of Philadelphia, Penn., has let a contract for an addition to its factory to cost approximately $50,000.

The Yarnall-Waring Co., in order to obtain even greater benefit from a widely established reputation for efficient power plant accessories, has decided to group its several products under the family name of "Yarway."

The Machinery Sales Department, operated by the Merchants and Manufacturers Exchange of New York, is now establishing a permanent machinery exhibit and salesroom at Grand Central Palace, 46th to 47th St. and Lexington Ave., New York City, where prospective buyers may be shown up-to-date machinery and mechanical appliances, get first-hand information and at the same time place their business. Machinery manufacturers and allied industries can rent suitable offices and exhibition space by communicating with the Machinery Sales Department, Grand Central Palace, New York. L. R. Duffield, formerly of the Philadelphia Bourse, is now in charge here.

Trade Catalogs

Rails, Etc. Walter A. Zelnicker Supply Co., St. Louis, Mo. Bulletin 237. Pp. 17; 3½ x 8¼ in.; illustrated. Free copy upon request.

Automatic Reclosing Circuit Breakers and Relays. The Automatic Reclosing Circuit Breaker Co., Columbus, Ohio. Bulletin No. 30, Pp. 20; 8¾ x 11 in.; illustrated; general description, theory and application.

The "De La Vergne" Counter-Current Ammonia Condenser. De La Vergne Machine Co., Foot of E. 138th St., New York. Bulletin No. 174. Pp. 8¾ x 11 in.; illustrated.

Pipe Tools. Greenfield Tap and Die Corp., Greenfield, Mass. Catalog No. 38. Pp. 32; 4¾ x 7¼ in. Describing and illustrating complete line of pipe tools made by the various divisions of this corporation. Copy mailed free upon request.

Link-Belt Roller Chain. Link-Belt Co., Chicago, Ill. Book No. 358. Pp. 16; 6 x 9 in.; illustrated. Giving information on recent roller-chain developments.

Motor Driven Compressors—Westinghouse and National Types. Westinghouse Traction Brake Co., Industrial Dept., Pittsburgh, Penn. Publication No 9035. Pp. 113; 6¼ x 9¼ in. Describes and illustrates fully both lines of compressors and accessories, with complete information relative to sizes, capacities, ratings and dimensions, in tabulated form.

Diamond Soot Blowers. Diamond Power Specialty Co., Detroit, Mich. Bulletin 119. Pp. 48; 7¾ x 10¾ in. A review of current mechanical soot-blower practice, fully illustrated; with data on boiler-room efficiency, insuluminium, venturi nozzles, etc A copy of the bulletin will be furnished free upon request.

Reilly Steam Pumps and Air Compressors. National Foundry and Machine Co., Inc., Louisville, Ky., Vogt Bros. Manufacturing Co., of Louisville, are now exclusive manufacturers. Catalog No. 12. Pp. 160; 5¼ x 7¾ in.; copiously illustrated with information covering the various types of pumps and compressors; many useful engineering tables; indexed.

Industrial Storage-Battery Locomotives. The Jeffrey Manufacturing Co., Columbus, Ohio. Catalog No. 231. Pp. 24; 6 x 9 in. This catalog contains interesting illustrations and description of various installations, and other useful data. A free copy may be obtained by writing to the company's main office or to any of its branch offices.

NEW CONSTRUCTION

Proposed Work

Mass., Canton—The Springdale Finishing Co. is having plans prepared by A. Wright, Arch., 73 State St., Boston, for a 2-story, 45 x 55 ft., reinforced concrete, steel and brick power house to be erected on Pine St. Estimated cost, $20,000. F. Meyer, Mgr.

Mass., Sherborn—The State will soon receive bids for the erection of an concrete power house and the installation of 1 new engine generator and 3 tubular boilers, etc. Estimated cost, $68,211. R. D. Kimball Co., 6 Beacon St., Boston, Engr.

Conn., Bridgeport—The United Illuminating Co has been granted authority by the Public Service Commission to build a 3 conductor, 660 volt transmission line.

Conn., Thamesville (Norwich P. O.)—The Eastern Connecticut Power Co., c/o R. W. Perkins, Norwich, has had preliminary plans prepared by H. M. Hope Eng. Co., Engr., 185 Devonshire St., Boston, Mass., for the erection of a 1-story, 80 x 140 ft. brick power house here.

N. Y., Freeville—The Groton Electric Power Corporation, Groton, plans to build a new power plant here.

N. Y., Waterville—The Waterville Gas and Electric Co. has filed a petition with the Public Service Commission for authority to build and operate an electric distributing system here. R. Thomas, Ch. Engr.

N. J., Trenton—City plans to build a new 2-story, 26 x 300 ft. boiler plant in connection with the Municipal Hospital. Estimated cost, $85,000.

Penn., Newcastle—The Grasselli Powder Co., 589 Arcade, Cleveland, Ohio, will build a 1-story, 100 x 125 ft. brick, reinforced concrete and steel power house. Estimated cost, $100,000.

Penn., Parkesburg—The Parkesburg Iron Works plans to build an addition to its boiler house. Estimated cost, $18,000.

Md., Baltimore—The Consolidated Gas, Electric Light and Power Co., Lexington and Liberty St., Baltimore, will build a 4-story, 100 x 200 ft., concrete, steel and brick, boiler house at Westport. Estimated cost, $100,000. Noted Nov. 13.

Md., Mt. Airy—The Mount Airy Ice and Electric Co. plans to install an additional generating unit. C. C. Riddlemoser, Mgr.

N. C., Pine Level—The Citizens Power and Light Co. plans to build an electric transmission system connecting 2 towns and a substation in each one. C. L. Goodwin, owner.

N. C., Reidsville—City voted $10,000 bonds for extensions and improvements to its electric lighting plant.

S. C., Sumter—City plans to build an electric lighting plant.

Ga., Commerce—City plans an election soon to vote on $15,000 bonds for the erection of an electric lighting plant.

Ga., Macon—The Macon Gas Co. will expend about $40,000 for improvements to its plant. A. Magraw, Gen. Mgr.

Ga., Ty Ty—City voted $7000 bonds to build an electric lighting plant.

Miss. Fondren—The State Insane Hospital is in the market for two 250 hp. boilers, water heaters, traps, valves, feed water pumps, smoke stack, stokers, ash conveyers, etc., for its new boiler house. R. L. Paquette, Box 31, Ch. Engr.

Ohio, Cleveland—City will soon award the contract for the superstructure of a 1-story, 169 x 175 ft. power house to be erected on East 53rd St. High pressure boilers, 25,000 kw. generator, switchboards and other equipment will be installed. Estimated cost, $525,000. J Tufal, East 53rd St. Station, Engr.

Ohio, Hamilton—The Hamilton and Rossville Hydraulic Co plans to build a power plant in connection with a new plant soon to be erected. Stone & Webster, Engrs.

O., Lowellville—The Mahoning and Shenango Ry. and Light Co., 25-31 E. Boardman St., Youngstown, will build a transmission line from here to McDonald. R. T. Sullivan, Mgr.

Ohio, Ravenna—Portage Co. will soon receive bids for the erection of an electric transmission line from intersection of Ravenna-Mantua Rd. with east and west road 3 miles north of courthouse. Estimated cost, $1,521.

Ind., Attica—The Attica Electric and Power Co. has been authorized to issue $50,000 in stock and $50,000 in bonds for the erection of an electric light and power plant to replace one recently destroyed by fire.

Mich., Flint—The Citizens Hotel Co., Ellicott Sq., Buffalo, N. Y., is in the market for complete power equipment, 500 hp.

Ill., Homer—The Homer Electric Light and Power Co. plans to extend its transmission line from here to Fairmount. W. S. Thompson, Mgr.

Ill., Oaklawn—The Chicago and Eastern Illinois R.R., Chicago, is having plans prepared for the erection of an addition to its power house here. L. C. Hartley, 66th and Union Ave., Chicago, Ch. Engr.

Wis., Camp Douglas—The Orange Light and Power Co. plans to extend its transmission line from here to Hustler. A. M. Patterson, Mgr.

Wis., Eau Claire—The Sacred Heart Hospital is having plans prepared by Foeller & Schober, Engrs., 123 North Washington St., Green Bay, for the erection of a 40 x 95 ft. boiler house and laundry.

Wis., Markesan—The Wisconsin Power, Light and Heat Co., Milwaukee, has purchased the Omro Electric Light Co., Omro, and plans to extend the Kilbourn and Prairie du Sac transmission lines from here to Berlin and Omro. E. B. Hemibach, Supt.

Wis., Orfordville—The Orfordville Light and Power Co. plans to build a 4½ mi., 3 phase, 60 cycle, 6600 volt, transmission line. A. E. Tomlin, Secy.

Wis., Rewey—The Mineral Point Public Service Co. plans to build a 33,000 volt transmission line from here to Platteville to connect with lines of the Interstate Light and Power Co., Galena, Ill. J. C. Meiners, Milwaukee, Pres.

Iowa, Eddyville—City voted $8000 bonds for improvements to its electric lighting plant. Noted Jan. 15.

Iowa, Sioux City—The Phillip Bernard Co. plans to build a heating plant and factory warehouse north of its factory on Floyd Ave. Estimated cost, $100,000.

Kan., Luray—City will soon award the contract for the erection of an addition to its electric lighting plant. Plans include the construction of a new power house and the installation of equipment.

Kan., Rossville—The Rossville Electric Light and Power Co. plans to enlarge its plant and extend its transmission line to Delia, Silver Lake and Willard. J. W. Phares, Pres.

Neb., Beaver Crossing—City plans to issue $9000 bonds for the installation of an electric lighting plant.

Neb., Schuyler—City is having preliminary plans prepared by the Electrical Development Co., Sioux City, Iowa, for improvements to its electric lighting plant.

S. D., Blackwell—City voted to issue bonds for improvements to its electric lighting plant and water-works system.

Mo., Garden City—The Green Light and Power Co., Pleasant Hill, has purchased the plant of Kaufman & Son, and plans to build a transmission line soon.

Mo., Kansas City—The Southwestern Milling Co., Dwight Bldg., is in the market for 400 hp. power plant equipment.

Mo., Otterville—K. Starten plans to install an electric lighting plant here.

Tex., Humboldt—City plans to improve its electric lighting plant. Plans include the installation of a new 300 kw. turbine, condenser and auxiliaries. W. M. Case, Gen. Mgr.

Okla., Hartshorne—The Choctaw Power and Light Co., McAlester, has been granted a franchise to build and maintain an electric lighting plant here. W. H. Vorce, McAlester, Gen. Mgr.

Okla., Ryan—City plans to install a crude oil engine in its electric lighting and water-works plant. W. C. Willard, Gen. Supt.

Okla., Shawnee—C. Sells, Commissioner of Indian Affairs, Washington, D. C., will receive bids until Apr. 30, for the installation of a steam heating system in the Shawnee school.

Ariz., Phoenix—The State Hospital for Insane has plans under way for the erection of a power house.

Wash., Bremerton—The Bureau of Yards and Docks, Navy Dept., Wash., is in the market for 2 turbo generators. Estimated cost, $90,000.

Wash., Hoquaim—The Lamb Machine Works plans to install an electric steel furnace in its proposed foundry and machine shop.

Wash., Spokane—The Loon Lake Copper Co. plans to install electric motors to operate all mining equipment. F. G. Crane, Secy.-Treas.

Ore., Mapleton—The North Star Power Co. plans to build 2 miles of transmission line.

Ore., Portland—The Electric Steel Foundry, 24th and York St., plans to build a transformer station at its plant here.

Calif., Corcoran—The San Joaquin Light and Power Co., Fresno, plans to install an electrolier lighting system on Whitley Ave. G. Wilson, Fresno, Gen. Mgr.

Calif., Redding—The Shasta Land and Timber Co. of Redding plans to rebuild its electric power plant and planing mill which was recently destroyed by fire. Loss about $45,000.

Ont., Alvinston—City plans to install power machinery.

CONTRACTS AWARDED

Conn., North Grosvenordale—The Grosvenordale Co. has awarded the contract for building, rearranging and altering its electric power station, to the J. W. Bishop Co., Worcester, Mass. Estimated cost, $30,000.

N. Y., Rochester—The Department of Public Works has awarded the contract for the erection of a new power house, to J. Friedericks & Son, Rochester, $12,739. Pumping machinery, engines, etc., will be installed. Noted Feb. 19.

Penn., Clifton Heights—The Kent Manufacturing Co. has awarded the contract for equipment as follows: coal conveyors, to R. H. Beaumont & Co., Drexel Bldg., Philadelphia, Pa., $7,500; boilers, to the Union Iron Works Co., Bourse St., Philadelphia, Pa., $20,000; pumps to the American Steam Pump Co., Commercial Trade Blk., Philadelphia, Pa., $1600. Noted Mar. 26.

S. C., Charleston—The Charleston Consolidated Ry. and Lighting Co. is building a 500 kw. rotary substation near the Navy Yard.

Ohio, Cleveland—The Steel Products Co., 2196 Clarkwood Rd., is having plans prepared by Burchard Roberts & Wales Co., Engrs., 622 Swetland Bldg., for a 1-story, 50 x 100 ft. heating plant to be erected on East 65th St. Estimated cost, $15,000.

Ohio, Columbus—The Ohio University has awarded the contract for the installation of a 6 retort boiler for the new power plant, to the Underfeed Stoker Co. of America, 111 West Monroe St., Chicago. Noted Oct. 30.

Ohio, Sandusky—The Good Samaritan Hospital has awarded the contract for the installation of electrical apparatus and fixtures, to the Bonn Electric Co. Estimated cost, $10,000.

Wis., Ashland—The Ashland Light, Power and Street Railway, 212 West 2nd St., is building a new hydro electric plant at Superior Falls. Estimated cost, $100,000. Noted Oct. 16.

Wyo., Lusk—The town has awarded the contract for the installation of a 100 hp. semi-Diesel oil engine, a 60 kv.-a., 60-cycle, 3 phase, 2300 volt generator, directly connected, and a 20 hp. motor for water-works, to the Fairbanks-Morse Co., 13th and Liberty St., Kansas City, Mo.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 11, 1918	Individual Apr. 11, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 11, 1918	Individual Apr. 11, 1918
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	5.10@5.85
Barley	3.40@3.65	3.10@4.10
Rice	3.90@4.10	4.10@4.85
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Apr. 11, 1918	One Yr. Ago	Apr. 11, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties April 11, 1918	Mt. Olive & Staunton April 11, 1918	Standard April 11, 1918
6-in. lump ...	$2.65-2.80	$2.65-2.80	$2.65-2.80
2-in.-lump	2.65-2.80	2.65-2.80	2.65-2.80
Steam egg....	2.65-2.80	2.65-2.80	2.65-2.80
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut.....	2.65-2.80	2.65-2.80	2.65-2.80
2-in. screen....	2.15-2.30	2.15-2.30	2.50-2.65
No. 5 washed..	2.15-2.30	2.15-2.30	2.50-2.65

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba.	2.40	2.65	2.15

Government figures.

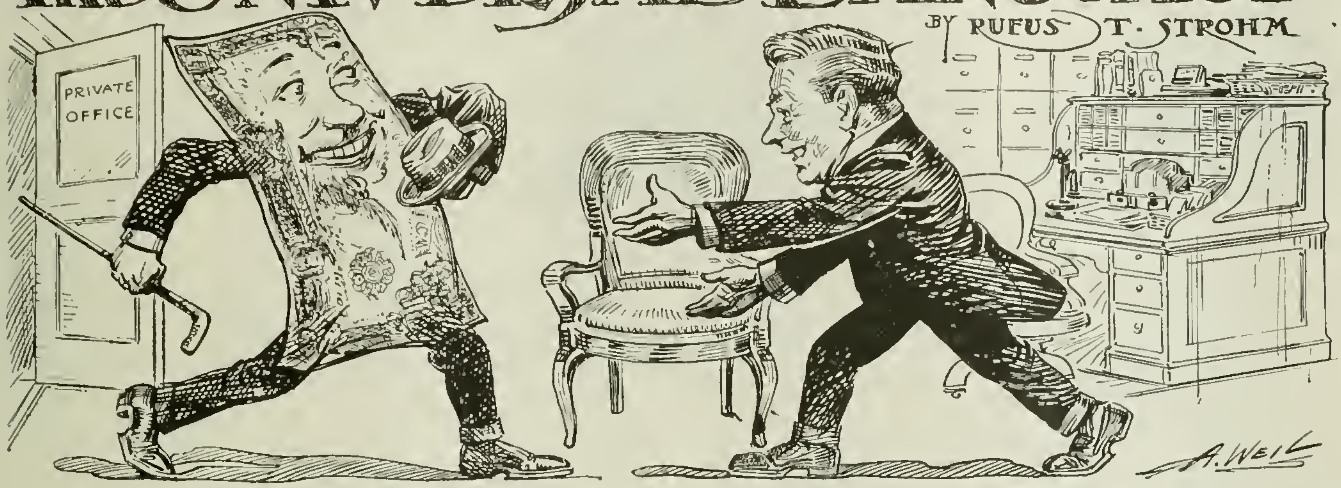
Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, APRIL 23, 1918 No. 17

THE UNIVERSAL LANGUAGE

BY RUFUS T. STROHM



NEARLY every power station owes its origin to men
Who expect the wealth invested to return to them again.
They are uninformed on technics, so that talk of B.t.u.'s,
CO_2 and kindred topics will but puzzle and confuse;
But they're clever at discerning how the cost of running trends,
And they show appreciation of substantial dividends.
Like as not they can't identify a gudgeon from a gland,
But the dollar talks a language that the owners understand.

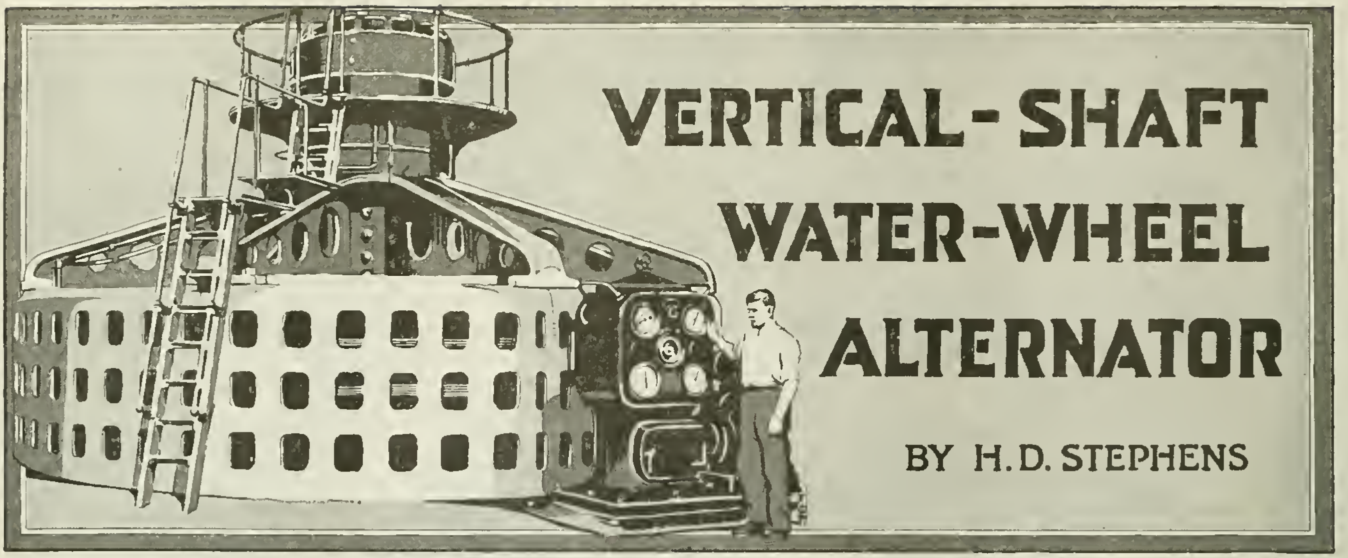
$

YOU have done your best to show them, in a mathematic way,
That you waste a lot of fuel through the ashpit every day,
And you've put the fact before them, just as plain as you can state,
That the economic method is to change the style of grate;
But their hearts are unresponsive and their eyes are hard and cold
Till you render the percentage of the saving into gold.
That's the sort of solar plexus that will never fail to land,
For the dollar talks a language that the owners understand.

YOU have doubtless had occasion to remind them of the need
Of a modern form of heater in connection with the feed,
And you've found that all your efforts were a simple waste of breath,
For their ears were deaf as marble and their lips were still as death.
So, suppose you change your tactics; jar their chill indifference
By translating facts and figures into quarters, dimes, and cents,
And they'll carry out your changes in the way that you have planned,
For the dollar talks a language that the owners understand.

$

IF a lessening of labor is the ground on which you rest
In the scheme of alterations or additions you suggest,
It is probable they'll bluster, and it's safe to say they'll growl,
And they'll meet your chain of logic with a fierce, forbidding scowl;
But their icy glance will soften and the frost will disappear
If you state how many shekels you can save them in a year,
And before you know what's doing, they'll be feeding from your hand,
For the dollar talks a language that the owners understand.



VERTICAL-SHAFT WATER-WHEEL ALTERNATOR

BY H. D. STEPHENS

Waterwheel-driven alternators may be classed under two types, vertical and horizontal. In this article the author describes the general construction, the thrust bearing, methods of lubrication and different schemes employed to drive the exciter, for the vertical type.

THE scarcity of coal which we have been experiencing has emphasized, perhaps as no other agency could, the urgent need for conservation of our natural resources, and action favorable to water-power development has been asked of Congress by President Wilson, and may therefore be hoped for in the near future.

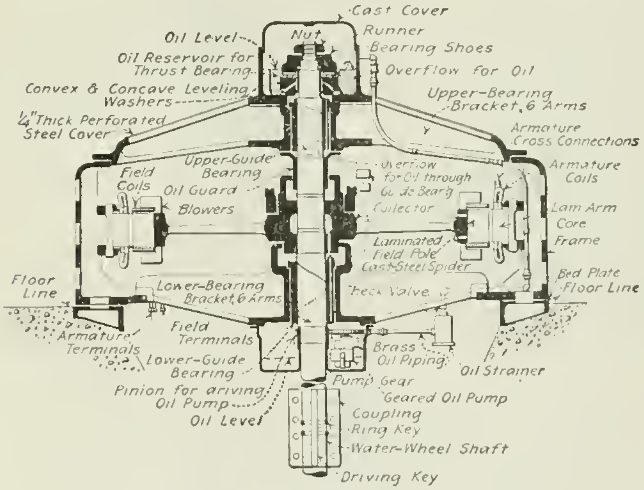


FIG. 1. CROSS-SECTIONAL VIEW OF VERTICAL WATER-WHEEL GENERATOR

With the prospect of considerable activity in water-power development during the next few years, the marked tendency toward a more universal adaptation of the vertical type of unit is of interest. Because of the high efficiencies obtained with the single-runner, vertical-shaft waterwheel, the simplicity of power-house layout and flexibility, as regards station-floor levels, permitted by its use, this type of prime mover becomes the logical choice for most low-head and for many high-head installations.

The vertical type cannot strictly be considered a new one, for it was used in the earliest developments at Niagara Falls; but it has only been within the last decade, and in fact since the advent of the high-efficiency, vertical, single-runner wheel, that its application has been seriously considered. if not actually adopted, for a majority of installations. Despite a very limited activity in hydro-electric work during most of this period, sufficient development has been going on to allow manufacturers and operators to work out those mechanical problems peculiar to the vertical unit to the satisfaction of both. While the wide range of capacity and speed encountered prohibits any absolute standardization of construction, the general problems of bearing supports, lubrication, etc., are common to all sizes, and the general standards resulting from a wide experience in this field are worthy of note. The information contained in the following paragraphs deals mainly with the product of the Westinghouse Electric and Manufacturing Company.

A typical cross-sectional view of a vertical generator is shown in Fig. 1, which covers a self-contained machine; that is, one with thrust bearing mounted on top of the generator, an upper and a lower guide bearing, one above and the other below the rotor, and arranged for connection to the waterwheel by means of a "muff" coupling. Most of the structural details of this type of unit are indicated in Fig. 1. The stationary frame extends, at both top and bottom, beyond the active section of the stator core a sufficient distance to form an adequate protection for the end turns of the armature winding. The cross-connections and wiring on the armature winding are on the upper side of the stator for convenience should any repairs after the initial installation be required. The leads from the armature and field and all the oil piping are ordinarily brought down just inside the stator frame in order to protect from possible injury.

Probably the most troublesome problem in early days involved the location of the thrust bearing. If this were mounted below the waterwheel, it was very inaccessible and therefore difficult to keep in repair. Mounted between the waterwheel and the generator, it usually required a special floor and therefore added expense to the cost of the power plant. It was finally decided to put this bearing on top of the generator, as shown in Fig. 1, and today practically all units being built are arranged in this manner. For a long time the thrust bearing itself was a matter of considerable concern. However, the introduction of the Kingsbury bearing has gone a long way toward eliminating, by its almost universal success over a wide range of capacity, the feeling of distrust of the vertical unit on this account. The detail of this type of thrust bearing is shown in Fig. 2. The bearing runs in a bath of oil, has exceedingly small frictional losses and therefore a low-temperature rise in service, and no appreciable wear.

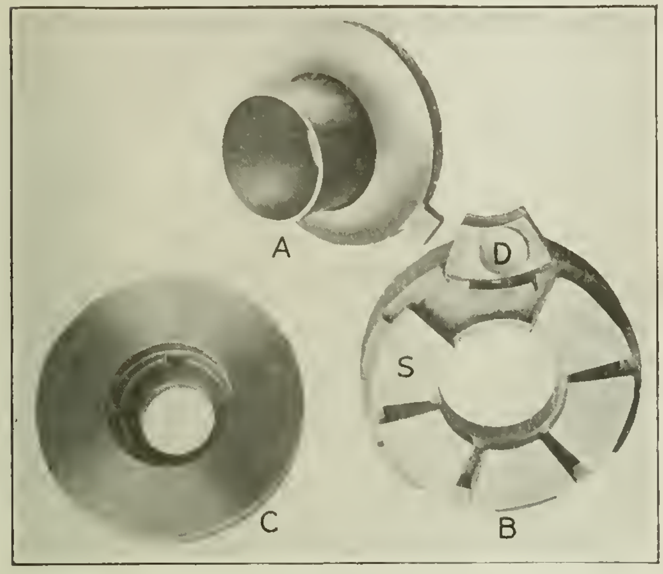

FIG. 2. PARTS OF KINGSBURY THRUST BEARING

As shown in the figure, the bearing consists essentially of three parts. *A* and *B* are what may be termed the convex and concave leveling washers, and *C* the runner; all three parts are contained in an oil-tight bearing housing and are shown at the top of Fig. 1. It will be seen that part *A* acts as a supporting casting to carry the entire weight of the revolving element. The concave surface on the lower side of part *B* rests on the spherical surface of part *A* to allow the proper alignment of the bearing. On the upper surface of part *B* are mounted a number of shoes *S*. Each shoe is babbitted on its upper surface and rests on a spherical seat on its lower surface, which in turn allows it to tip slightly when in operation. One of the shoes is shown turned over in Fig. 2 to show the spherical seat *D*. The runner *C* is a special casting which is securely fastened to the rotating shaft and rests on the shoes *S*, which tips slightly when the runner is revolving and allows a wedge-shaped film of oil to form between the runner and shoes.

There are four, six or eight shoes to a bearing, depending upon its size and the weight it has to carry. There is no direct contact between the shoes and the revolving runner except when the machine is at rest, and it has actually been found in practice that small tool marks on the babbitt surface exist for many months after the bearing has been in use. In other words, no appreciable wear can be detected.

The thrust bearing is called upon to carry heavy loads, from 300,000 to 400,000 lb. with the larger-capacity units, this being due to supporting not only the weight of the rotating element of the generator proper, all the shafting and the waterwheel runner, but also the unbalanced or downward force of the water which flows through the wheel when in service.

This necessitates an exceptionally sturdy frame and a heavy upper bracket having no appreciable deflection. A bracket with a number of I-beam section arms spaced equidistant around the periphery of the stator frame and bolted thereto has filled the requirements admirably and is now almost universally used (see headpiece and Fig. 3).

The bracket that supports the thrust bearing also carries a guide bearing, Fig. 1, whose function it is to center the rotor in the middle of the stationary part. This bearing is babbitt-lined. Immediately beneath the rotor a bracket similar to that used for supporting the thrust and upper-guide bearing is employed. This is also bolted to the stator frame, as in Fig. 1. Ordinarily, this bracket is employed only to house the lower-guide bearing, which is babbitt-lined, but in many cases, particularly with large-capacity units, it must be strong enough to support the rotor during dismantling, and in those cases where braking is necessary.

It has been found, particularly in many low-head installations, that the gates that shut off the water have sufficient leakage through them even when closed to cause the rotor to operate at a very slow speed and thus to endanger the thrust bearing. To prevent damage in such cases, suitably machined pad supports are provided on the lower-bracket arms to mount brakes or jacks. These brakes can be operated so as to bear upon a machined surface or circular plate on the rotor, to quickly bring the rotor to rest. To the lower bracket is also bolted an oil pan to catch the drain from the thrust bearing and from the two guide bearings.

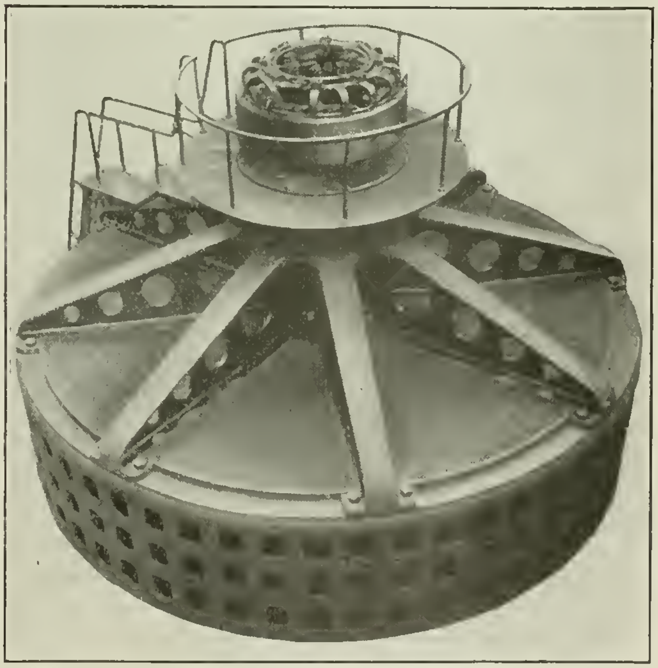

FIG. 3. VERTICAL ALTERNATOR, SHOWING I-BEAM METHOD OF SUPPORTING THRUST BEARING

Ordinarily, there is a break between the generator and the waterwheel shaft, as the mounting of the waterwheel runner on an extension of the generator shaft would involve considerably more headroom for installation and dismantling for repairs than would otherwise be required. The advantages to be gained by the use of a common shaft seldom compensate for the increased power-plant cost; therefore separate shafts are used. Connection between the two is made by either a "clamp" or "muff" type coupling, in which two machined pieces are bolted and keyed over the ends of the two shafts, or half-couplings forged directly on the generator and waterwheel shafts and the two connected rigidly together by bolts, are employed.

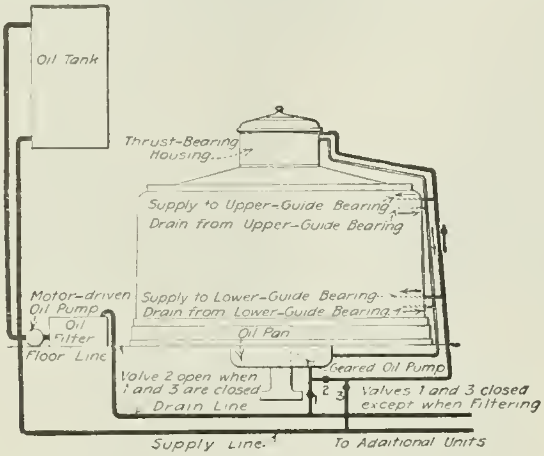

FIG 4.—DIAGRAM OF SEPARATE OILING SYSTEM

There are some cases, where the distance between the generator and the waterwheel runner is very small, in which the lower-guide bearing can readily be eliminated. Two different types of bearings are ordinarily used on the generator and on the waterwheel. The generator bearing is a babbitt-lined one, and any appreciable wear of the bearing surface is likely to cause vibration and trouble. The waterwheel bearing is ordinarily of lignum-vitæ blocks lubricated by water. These blocks are in a more or less inaccessible place and are rarely inspected or repaired. They can wear quite appreciably without causing serious trouble. When the generator has two bearings, these will often maintain true alignment even with considerable looseness around the waterwheel bearing. When only two bearings are employed, however, one on the generator and one on the waterwheel, any wear is found to immediately cause vibration and trouble. This, I believe, is the reason why it is so generally customary to employ the self-contained generator. It is somewhat questionable whether the danger has not been considerably exaggerated, since quite a number of installations have gone into service without a lower-guide bearing, and such installations are operating very satisfactorily.

Two general methods of lubrication for vertical machines are employed. On a machine where the flow of oil to the thrust and guide bearings does not exceed three or four gal. per min., a self-contained system, as shown in Fig. 1, is employed. The oil, from the pan bolted to the lower-guide-bearing bracket, is forced through brass piping by a small pump, gear driven from the main-generator shaft, as indicated. It flows through an oil strainer and then up into the housing holding the thrust bearing. Here provision for an adequate supply of oil for the guide bearings is made, and for the overflow. The drain from all bearings then flows back again into the lower oil pan. It is found that where the required amount of oil does not exceed the quantity specified, the oil is cooled sufficiently by radiation and no further means need be provided for cooling. As the system is an entirely closed one, there is little likelihood of dust or dirt getting into the oil, and operation for long periods of time without renewal is to be expected.

Where the weight carried by the thrust bearing is very heavy and where considerable quantities of oil are required, a separate oiling system is employed, the oil circulation through the machine proper being the same as that already described, except that instead of it returning and being pumped back into the system through a gear-driven pump on the main shaft, connections are made at the base of the generator for piping the oil into a common system. The oil flows from the pan at the base of the generator into a reservoir, from which it is pumped, usually through a filter, into a tank; from here the oil is returned to the various machines by means of gravity. Very considerable amounts of money can easily be spent on such a lubricating system. As the circuit is a closed one, it is not necessary to continuously filter all the oil from all the machines, and a filter having a much smaller continuous capacity can safely be installed. Cooling of the oil in the larger systems is usually accomplished by a flow of water through a coil of pipe placed in the reservoir or tank.

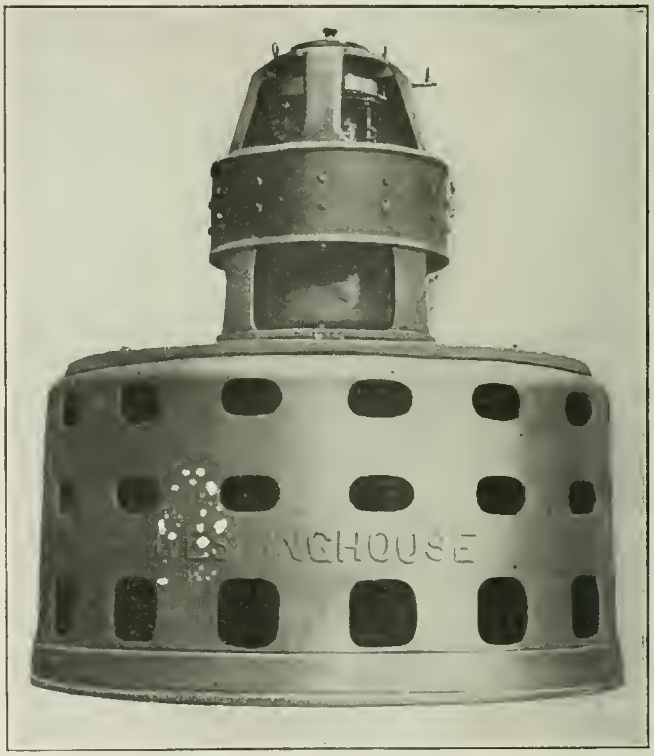

FIG. 5. VERTICAL WATERWHEEL ALTERNATOR WITH EXCITER MOUNTED ON TOP OF MACHINE

A system that is relatively inexpensive and that can be installed where several units of small capacity are employed, is shown in Fig. 4. Ordinarily, the oil flows through the closed system of each individual machine, but at intervals when it is desired to filter the oil from one unit, this is done by changing the valves shown and running the oil to be filtered through the filter into the supply tank. Brass piping throughout the entire supply system is preferable for the reason that such pipe does not corrode or rust.

By installing water-cooling coils in the thrust-bearing housing, very much the same effect can be gained as with the external-oiling system, as regards keeping the oil sufficiently cool for satisfactory service. While such methods are undoubtedly feasible, the water piping would necessarily take up a considerable space and therefore make the room normally available in the housing for inspection or repair very much congested. Furthermore, the carrying of water to the top of the generator, where a leak or break in the pipe during operation might result in considerable damage to the machine, is questionable.

The exciter problem, particularly with alternators that operate at slow speeds, is probably the most difficult of all the electrical ones in connection with the power-plant design, and the method that will combine maximum operating efficiency and minimum first cost and maintenance is found only after careful analysis.

Individual direct-connected exciters, as shown mounted on top of the machines, Figs. 3 and 5, should receive first consideration as giving the simplest and cheapest plan layout. In this consideration, however, certain fundamental facts concerning both alternating and direct-current generators appear: First, that the slower the speed of the alternator the greater is its percentage of excitation and the larger the exciter; second, that the slower the speed of the exciter the more expensive it is; third, that the slower the speed of the exciter the greater its field current and the more sluggish its operation, thus making the voltage regulator, now almost universally employed, both complicated and expensive. These factors may result in the direct-connected exciter being rejected on account of high first cost.

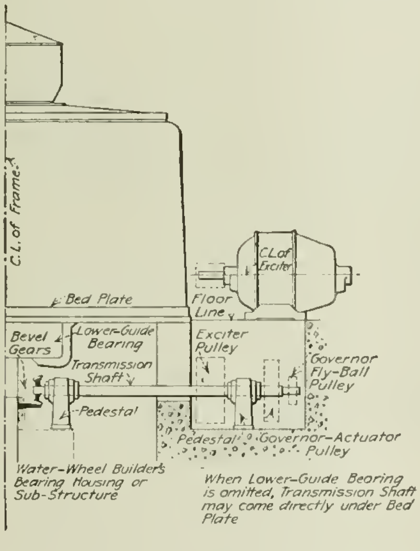

FIG 6 GEAR- AND BELT-DRIVEN EXCITER

Where generator capacities are relatively small, individual high-speed exciters may still be employed, as shown in Figs. 6 and 7. Both methods have certain disadvantages, one in the introduction of the gear and the other in a quarter-turn belt. Either method, however, is fairly inexpensive, and both seem to give fairly satisfactory results.

Next, separate waterwheel exciters may be considered. Such units ought not to be excessive in cost, but may introduce considerable expense in connection with building and wheel-pit costs. Also they may, because of the relatively small capacity of the wheel, require special and more expensive trash racks, etc.

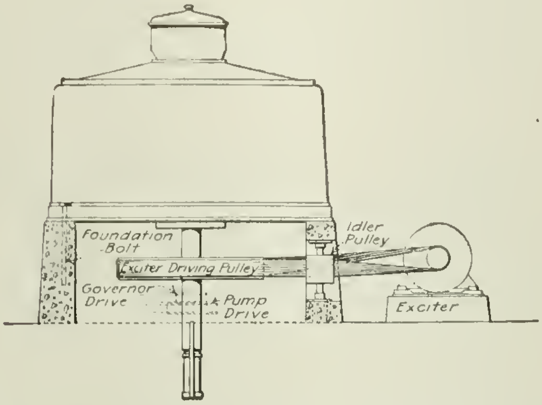

FIG. 7. QUARTER-TURN BELT-DRIVEN EXCITER

A method often used is a combination of waterwheel driven and motor-driven sets, the exciter driven by the waterwheel being used for starting the plant and as a spare, and high-speed motor-generator sets furnishing the excitation normally.

Any one of the foregoing methods may be considered as fairly standard, and the choice, of course, depends on the number of main units in the plant, relative costs of each method, conditions of operation more or less peculiar to the individual plant, etc. In general, it may be stated that the larger the capacity of the separate generating units and the higher their speed, the more favorable becomes the indivdual direct-connected exciter layout.

Heat Transfer

Radiation of heat takes place between bodies at all distances apart. Heat rays proceed in straight lines, and the intensity of the rays varies inversely as the square of their distance from the source.

Conduction is the transfer of heat between two bodies or parts of a body which touch each other. Internal conduction takes place between the parts of one continuous body and external conduction through the surface of contact of a pair of distinct bodies. The conduction of heat through a stagnant mass is very slow in liquids and almost, if not wholly, inappreciable in gases. It is only by the continual circulation and mixture of the particles of fluid that uniformity of temperature can be maintained in the fluid mass, or heat transferred between the fluid and a solid body.

Convection, conveying or carrying of heat means the transfer or diffusion of heat by means of the motion of the mass.

Where are the spendthrifts of yesteryear? Buying Liberty Bonds. The air of liberty, they find, is better than champagne, and the effect lasts longer.

Stoker Capacity vs. Boiler Forcing Rates

BY JOSEPH T. FOSTER*

This article suggests ways in which the plant owner can check his boiler performance against any well-defined standard and ascertain what improvements will result if certain changes are effected.

EVERY central station and plant operating boilers and prime movers is striving, or at least should strive to do two things: To get the maximum output from existing equipment without loss of time or expenditure of money for extensive rearrangement and to eliminate every possible item of waste, particularly the waste of coal, not only because of its present high price, but also because of the diminution in the available supply. From present indications the need for economy will not cease with the war, as the ensuing period will be one of readjustment and will probably be accompanied by high operating costs in every branch of industry.

Many companies have their boilers equipped with instruments to give data on boiler performance and conduct boiler tests at intervals for the purpose of showing up any abnormal conditions. The usual boiler test is susceptible of a certain amount of analysis, and it is possible to tell whether the boiler performance was good or only fair under the conditions of test, but it does not tell whether a boiler is doing its best day after day. There seems to be no way in which the plant owner can survey the whole situation, check his boiler performance against any well-defined standard and ascertain what improvement might be realized if certain changes were made. It is the purpose of this article to supply such a standard and to suggest ways to compare a given performance with the best. Predictions as to economical forcing rates for boilers have been based chiefly on the square feet of heating surface without sufficient regard to the square feet of grate surface or the pounds of coal burned per square foot.

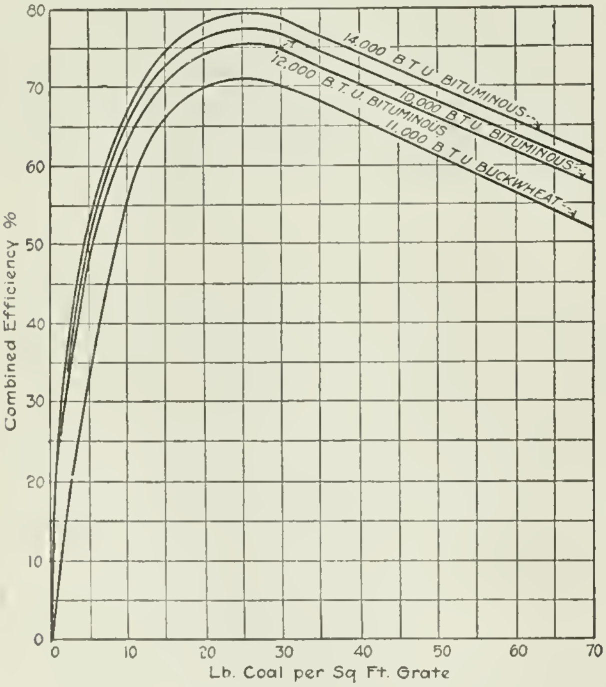

FIG. 1. RELATION BETWEEN COMBINED EFFICIENCY AND COAL BURNED PER SQUARE FOOT OF GRATE

It is difficult to see why variation in efficiency should be so commonly referred to square feet of heating surface or, what amounts to the same thing, to the percentage of the nominal rating. When a boiler is properly designed as regards heating surface, efficiency is a function of the furnace conditions only, and these are in turn dependent on the number of square feet of grate. Recently the tendency has been to give proper attention to this phase of the matter, and larger grate areas are becoming more common. A larger grate means a larger volume of hot gases and, by the moving back of the bridge-wall, a larger amount of tube surface exposed to the direct radiation from the fuel bed. The gain is therefore twofold.

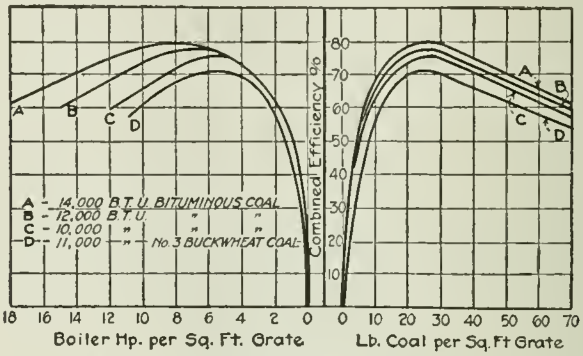

FIG 2. COMBINED EFFICIENCIES AT VARIOUS STOKER FORCING RATES

Formulas have been developed for computing combined efficiencies at various forcing rates, but such formulas are based on heating surface and the results obtained from them are empirical for a given size and type of grate. The efficiency formulas were of greater service some ten years ago, when there was a more definite relation between heating surface and grate surface. A definite relation existed then because with hand firing the depth of grate was limited by the ability of the fireman to handle the coal, and 6- or 6½-ft. grates were the rule. With a definite ratio between heating surface and grate surface the empirical formula developed for one set of conditions could be applied to other conditions with some degree of accuracy. B.t.u. input is certainly the governing factor in boiler output, and since the heat input is directly dependent on the amount of grate surface, this surface is the datum from which calculations should be made.

Boiler tests prove that the plotting of combined efficiency against the pounds of coal burned per square foot of grate surface shows a characteristic curve which has a definite form regardless of the character of the fuel or the size of the boiler. Fig. 1 shows the form of curves derived from actual tests. The curves for bituminous coal were obtained from tests on a battery

---

*Public Service Electric Company, Newark, N. J.

of 1400 rated horsepower boilers and the curve for the buckwheat is a composite from numerous tests on boilers varying in capacity from 1000 to 250 hp. It will be noticed that the curves have the same general characteristics even though boiler capacities and kind of fuel varied widely. All grades show best efficiency at a rate of about 25 lb. of coal per square foot of grate surface per hour. Boiler-heating surface seems to have been pretty definitely fixed at 10 sq.ft. per nominal horsepower, and on this basis the curve will be of value in predicting efficiencies at various forcing rates.

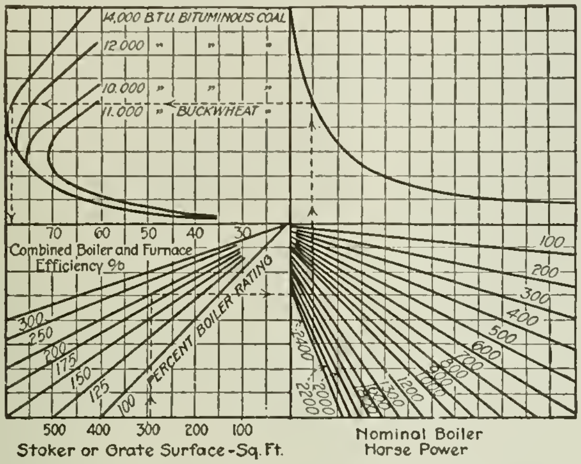

FIG. 3. RELATION OF BOILER HORSEPOWER PERCENTAGE RATING, GRATE SURFACE AND EFFICIENCY

Fig. 2 is a combined curve showing efficiencies plotted against pounds of coal per square foot of grate per hour and boiler horsepower per square foot of grate. The effect of the burning qualities of the fuel on the output is very marked. The most economical forcing rate for the 14,000-B.t.u. coal is 9 boiler horsepower per square foot of grate and for the buckwheat 6 hp. There is also a difference of approximately 10 per cent. between the best efficiencies realized.

Fig. 3 is a chart worked out on the basis of test results and shows the relation between combined efficiency and grate surface for various sizes of boilers under different operating conditions and with different kinds of fuel.

Example 1: What efficiency will be obtainable with a 1400-hp. boiler having 290 sq.ft. of grate surface when operated at 200 per cent. rating with 14,000 B.t.u. coal?

Solution: Project upward from 290 sq.ft. of grate surface to the 200 per cent. rating line, then horizontally to the right to the 1400 nominal horsepower line, then vertically to the curved transfer line and horizontally to the left to the point of intersection with the efficiency curve, thence vertically downward read the efficiency as 78.5 per cent.

Example 2: A boiler with a nominal rating of 1000 hp. and having 350 sq.ft. of grate surface is being operated at 150 per cent. rating on 12,000-B.t.u. coal. Is it developing its best efficiency, and if not, at what rating should it be run?

Solution: Following out the method outlined, it will be seen that the boiler is developing 73.5 per cent. efficiency. The best efficiency with this coal is 77.5 per cent. Reversing the operation by projecting horizontally from the point of best efficiency of the curve for 12,000-B.t.u. coal to the transfer line, downward to the nominal rating curve, horizontally to a vertical line from 350 sq.ft., read 230 per cent. as the rating at which to operate the boiler for maximum efficiency. Where a number of boilers are on the line operating under the conditions in the second example, it would be possible to cut out one or more boilers with a large fuel saving on account of the increased efficiency of the remaining boilers at the higher rate of steaming.

The practical use of this method will be recognized and the following instance is a case in point: The initial installation in a certain plant consisted of a battery of boilers with 221 sq.ft. of grate surface and rated at 1400 hp. and operated at 79 per cent. efficiency when developing 145 per cent. rating, burning 14,000-B.t.u. coal. Increased load on the plant required a second installation, and it was desirable that it should develop its best efficiency at a higher rating. It was therefore designed with a grate surface of 291 sq.ft. and will develop 79 per cent. efficiency at approximately 200 per cent. rating. It is much cheaper to develop greater horsepower by means of larger grates than by increasing the boiler-heating surface, for large heating surface involves high initial cost not only of the boilers themselves, but of all the other items entering into their erection. Where cubic feet of available space in the boiler house is limited, the question of grate surface is of importance because every unnecessary cubic foot taken up by the boilers means a higher plant cost. The question of grate area, however, is not limited to new plants, but is of equal importance where the boilers are already installed. Where the grate surface is found to be too small, it would be profitable in almost every instance to spend the money necessary to enlarge it.

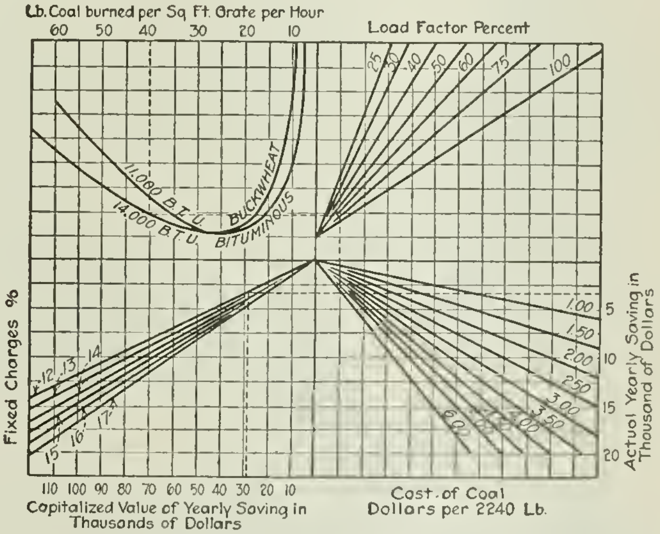

FIG. 4. CAPITALIZED VALUE OF SAVING REALIZED BY OPERATING AT BEST FORCING RATE

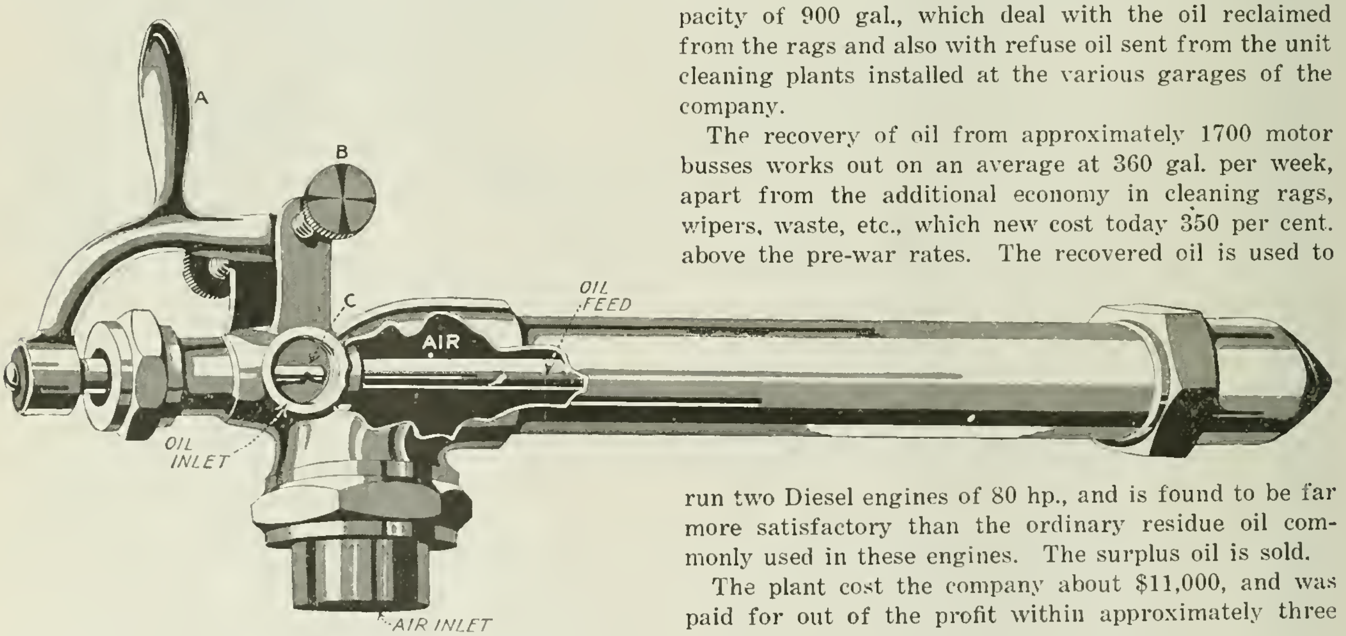
Fig. 4 is designed to show in dollars the saving which will result from changing from a given condition to the best condition, as shown in Fig. 1; namely, 25 lb. of coal burned per square foot of grate per hour, for various load factors and coal prices. The value of the annual saving, capitalized at from 12 to 17 per cent., is also given. All values are calculated for a 1000-hp. load, the data for other loads being proportionate. Only two grades of coal are shown in this chart, but other grades, since they fall between the two, can readily be interpolated. Example: A boiler is being forced so that 40 lb. of coal is burned per hour per square foot of grate. What saving would be realized yearly if the forcing rate were brought down to the foregoing standard, 25 lb. per sq.ft. per hour, or the most economical value? How much money could be profitably spent for additional boiler capacity to bring about this result if coal is $6 per ton and the saving is capitalized at 12 per cent., and 75 per cent. is the assumed load factor?

Solution: Project downward from 40 lb. the coal burned per hour per square foot of grate to intersect with the 14,000-B.t.u. curve, then horizontally to the right to the 75 per cent. load factor line, then vertically down to the cost of coal per ton, $6. From this point horizontally read on the right-hand scale the yearly saving, $3250, or horizontally to the left to the 12 per cent. line and vertically downward read the capitalized value, $28,000, the amount that could profitably be spent for additional boiler capacity.

The application of the curves is not confined to problems covering boilers already equipped, but can be used equally well for calculating the saving that would result in some cases from the use of stokers on hand-fired boilers. Assuming hand-fired boilers in which a rate of eight pounds of coal per square foot of grate per hour is maintained, the boiler efficiency would be approximately 60 per cent. With a stoker that will burn 25 lb. per sq.ft. per hour, the capitalized value of the stoker can be read from the curves in the same manner as described in the foregoing examples.

Johnson Crude Oil Burner

There are sections throughout the United States where crude oil is preferable to coal as a fuel under both heating and power boilers. In competition with coal 130 gal. of the cheapest grade of California fuel oil, containing about 18,500 B.t.u. per lb., is equal in heating value to one ton (2000 lb.) of the best grade of soft coal. In burning crude oil a burner of proper construction must be used.



SOME OF THE DETAILS OF CONSTRUCTION OF THE JOHNSON OIL BURNER

A low-pressure air crude-oil burner manufactured by the S. T. Johnson Co., Grace and Lowell Sts., San Francisco, Calif., has been developed to burn any kind of thick or thin oil, or oil containing water in emulsion.

Referring to the illustration, the burner is designed to vaporize heavy crude oil with an air pressure of between 1 and 5 lb. The burner has a 1-in. air connection and a ¾-in. oil connection and is furnished with an angle-ported valve *C*, which closely regulates the supply of oil to the furnace. The control of the flame is obtained by the adjustment of the lever *A*, which is locked into position by the two thumb-screws *B*. Oil is fed to the burner nozzle through the pipe opening shown, and the air supply going through the nozzle head surrounds the oil pipe. The oil and air are mixed at the head, and the flame is produced close to the tip of the burner.

Where air pressure is not available, a pressure blower is used, which furnishes the necessary air to atomize the oil without heating it before it reaches the burner.

Rag Washing and Oil Reclaiming

The London General Omnibus Co., Ltd., London, England, has, for about three years, been working a central recovery plant for reclaiming the oil and grease absorbed in rags, which so washes the cleaning material itself that it can be used over many times.

The depot is situated at Riley St., Chelsea, S. W., and the plant consists of a horizontal return-tubular boiler, three centrifugal steam-driven oil extractors, two hydro-extractors, three rotary washing machines and one rotary drying machine, together with a calender and an ironing machine to deal with the washing and pressing of women's overalls. The plant, in effect, is a typical laundry-machinery equipment.

In connection with this plant there are three steam-heated, oil-cleansing or settling tanks, each with a capacity of 900 gal., which deal with the oil reclaimed from the rags and also with refuse oil sent from the unit cleaning plants installed at the various garages of the company.

The recovery of oil from approximately 1700 motor busses works out on an average at 360 gal. per week, apart from the additional economy in cleaning rags, wipers, waste, etc., which now cost today 350 per cent. above the pre-war rates. The recovered oil is used to run two Diesel engines of 80 hp., and is found to be far more satisfactory than the ordinary residue oil commonly used in these engines. The surplus oil is sold.

The plant cost the company about $11,000, and was paid for out of the profit within approximately three years.

Liberty bondholders are justly another Grand Army of the Republic. You should lose no time in becoming a member of so glorious an army, even if you have purchased bonds in the other loans.

The Electrical Study Course—Series-Connected Generators

A comparison is made between the shunt and series type of direct-current generators, showing how the voltage of the shunt type remains practically constant with different load values, while the voltage of the series varies with the load.

IN THE previous lesson we saw how a shunt generator was capable of building up a voltage from the residual magnetism in the fieldpoles when the field coils are connected to the armature in the proper relation, as in Fig. 1. In this case the field coils are connected across the armature, therefore the latter is capable of causing a current to flow through the former whether the armature is supplying an external load or not. In Fig. 1 the field circuit is from the positive brush through the field coils back to the negative brush without passing through terminals M and N, which lead to the external load, hence it is evident that the field circuit is independent of the load circuit.

In the series-connected generator, as in Fig. 2, it will be seen by following around from the brush marked plus through the field coils that in order for the circuit through the armature and field coils to be completed an external load L must be connected between terminals M and N, as in Fig. 3. In other words, the series generator cannot build up its voltage unless it is connected to a load.

Since the field coils of the series generator are connected in series with the load and armature, it is at once evident that the cross-section of the conductors in the field coils must be large enough to take care of the full-load current of the machine. The field coils on the shunt generator are connected across the armature and are wound with wire of a size that will make the coils of such a proportion as to produce the flux in the polepieces with the minimum expenditure of energy. The power required to excite the field coils is generally from about 1 to 3 per cent. of the output of the machine.

To generate a given voltage, the armature must revolve at a certain speed and the magnetic field of the polepieces must have a definite value. To set up the lines of force in the magnetic circuit, it is necessary that a required number of ampere-turns in the field coils, say 6000, be supplied.

Ampere-turns is the number of turns in a coil of wire multiplied by the current in amperes that flows through it when connected to an electric circuit; that is, if a coil contains 2000 turns and when connected to a 110-volt circuit, 3 amperes flow through it, then the ampere-turns are $2000 \times 3 = 6000$.

If we assume the machine in Fig. 1 to require 6000 ampere-turns to excite the field coils sufficiently for the armature to generate 110 volts, and further assume that the full-load current of the machine is 100 amperes and requires 3 amperes to excite the field coils, then the number of turns in the field coils will be ampere-turns divided by amperes, or $6000 \div 3 = 2000$, and the resistance of the wire in the field coils is volts divided by current, or $110 \div 3 = 37$ ohms approximately.

If the series machine, Fig. 3, is assumed to have the same capacity as the shunt machine, Fig. 1, and requires the same number of ampere-turns to excite the field coils as the shunt machine to generate 110 volts, then the number of turns of wire required in the field coils, since the total current is flowing through the field winding, will be $6000 \div 100 = 60$ turns, or 30 turns on each coil. Since the total current flows through the field coils and load in series, the combined resistance of the field coils and load can only be volts $\div$ amperes, or in this case, $110 \div 100 = 1.1$ ohms.

Now if we are to keep the amount of power expended in the field coils on the series machine down to approximately that of the shunt machine, or 3 per cent., then the resistance of the field coils can be only 3 per cent. of the total resistance, or $1.1 \times 0.03 = 0.033$ ohm, or the resistance of the field coils in the shunt machine is $\frac{37}{0.033} = 1121$ times that of the series machine. Herein lies the most prominent structural difference between the shunt and series type of machines. The field coils on the shunt machine are wound with a large number of turns of small wire having a comparatively high resistance and are connected in parallel with the armature. The field coils of the series machine are wound with a small number of turns of large wire, consequently have a low resistance and are connected in series with the armature. However, the size of the conductors in either case varies with the size and the voltage of the machine.

The comparison of the field coils in the foregoing is not absolutely correct, because, in the first case we assume 110 volts at the brushes and in the series machine we have assumed that the total pressure generated is 110 volts. However, the comparison is close enough for all practical purposes and eliminates a lot of calculation.

It is evident that with the series generator if the field strength is to be maintained constant, consequently the voltage at the brushes at a constant value, the load also will have to be maintained at a constant value. This is generally a difficult thing to do, since the load on a generator is usually made up of a number of different devices used for different purposes and of different sizes and types, which are connected to the circuit when wanted and disconnected when not required. The devices also require approximately a constant voltage for their operation. Such a condition cannot be met very successfully by the series generator.

From what we have already seen of the shunt generator, it is evident that the load on the machine does not affect the field circuit. For example, in Fig. 4 is given a shunt generator supplying a load of four resistances, r_1, r_2, r_3 and r_4 each of 4 ohms, in parallel. If we assume that the armature develops 100 volts and neglecting the effect of the armature resistance, the current i flowing in each section of the load is $i = \frac{E}{r} =$

$\frac{100}{4} = 25$ amperes, or a total of 100 amperes in the four circuits. If one resistance is disconnected from the circuit, the current supplied to the load will be 25 × 3 = 75 amperes, and if only two are connected, the current delivered to the load by the armature is 50 amperes, and for one resistance, 25 amperes. Under any one of the conditions the current flowing in the field coils will remain practically constant since, as shown, this circuit is independent of the load. Consequently, the value of the field current is not affected by the load only as the voltage is caused to vary slightly by the load current and resistance of the armature. This latter factor will be considered in the next lesson.

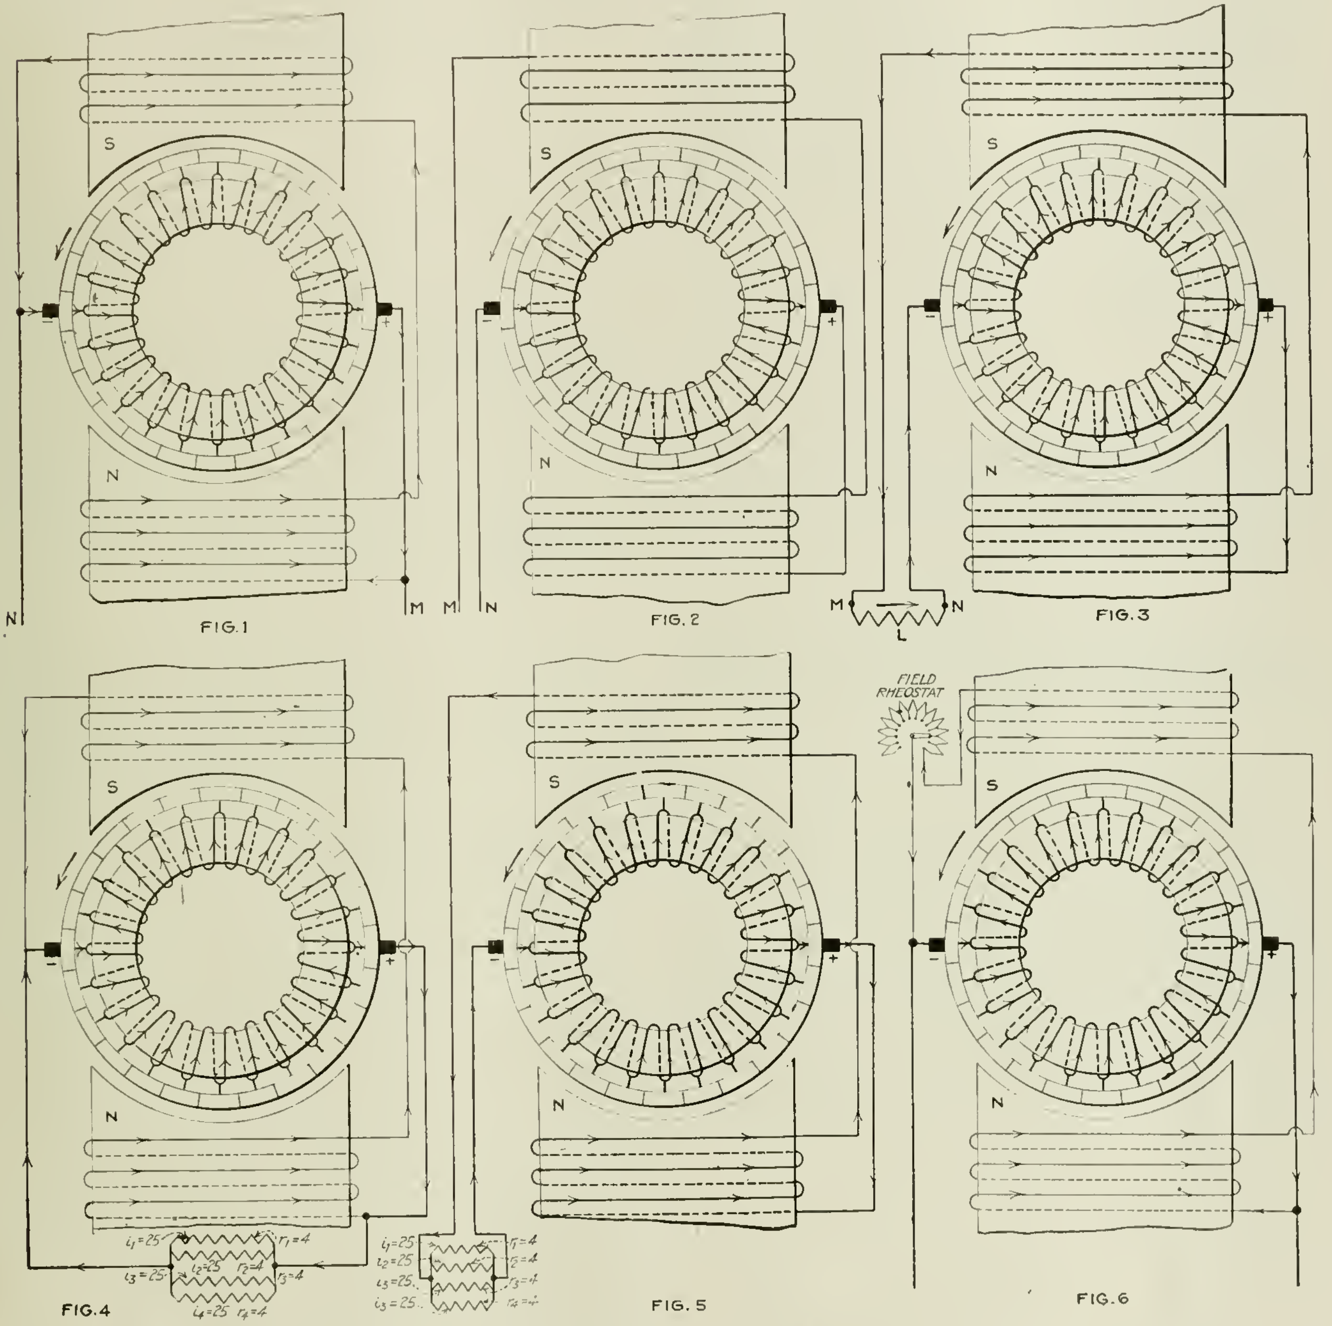

FIG. 1 FIG. 2 FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 1 TO 6. DIAGRAMMATICAL REPRESENTATION OF SHUNT AND SERIES GENERATORS

Now consider what would happen if we varied the load on the series generator, Fig. 5, the way that it was changed on the shunt generator, Fig. 4. In Fig. 5, if we assume the machine to be generating 100 volts and that 100 amperes is flowing in the circuit, then 100 amperes is passing through the field coils. If one section of the load was taken off and if the voltage at the armature terminals remained constant at 100 volts, as was assumed in the shunt machine, 25 amperes would flow through each of the three resistance elements, as in Fig. 4. But with the series machine the pressure will decrease since the current has been decreased in the field coils, consequently the current will decrease in the different elements connected across the armature terminals. From this it is evident that as the load is decreased on the series machine the voltage is decreased and the current through each individual load also decreases; whereas, on the shunt generator the total load may be varied, but the current in the individual loads and the voltage remains practically constant.

What we have just seen has practically eliminated the series type of machine from commercial use in preference to the shunt type or modifications of this latter type.

Direct-current generators are generally designed so that, if the shunt-field winding is connected directly across the armature, as shown in Fig. 1, they will at rated speed develop about 120 per cent. normal volts, that is, a 110-volt machine will generate about 125 or 130 volts. The voltage is then adjusted to normal by connecting an adjustable resistance in series with the field circuit, as in Fig. 6. The current through the field coils is adjusted by means of this resistance so as to produce normal volts. Then any slight variation in the voltage, due to changes in load or otherwise, can be taken care of by varying the resistance in the field circuit. The resistance connected in series with the field coils is called a field rheostat.

Fig. 7 is a layout of problem 1 in the last lesson. The joint resistance of the circuit is

$$R = \frac{1}{\frac{1}{r_1} + \frac{1}{r_2}}$$

In the problem the joint resistance R is known and r_2, one of the individual resistances, is to be determined. This may be found by transposing the joint-resistance formula around to read

$$r_2 = \frac{1}{\frac{1}{R} - \frac{1}{r_1}} = \frac{1}{\frac{1}{3.75} - \frac{1}{6}} = \frac{1}{\frac{6}{22.5} - \frac{3.75}{22.5}} = \frac{22.5}{2.25} = 10 \ ohms$$

The correctness of this answer may be checked by substituting the values in the joint-resistance formula; then

$$R = \frac{1}{\frac{1}{6} + \frac{1}{10}} = \frac{1}{\frac{8}{30}} = \frac{30}{8} = 3.75 \ ohms$$

In Fig. 8 is problem 2 of the previous lesson. The resistance of each lamp is 220 ohms and that of the voltmeter 10,956 ohms. The joint resistance of the five lamps is equal to the resistance of one lamp divided by the number of lamps in parallel, or 220 ÷ 5 = 44 ohms. Since the group of lamps is in series with the voltmeter, the total resistance of the circuit is $R = 44 + 10{,}956 = 11{,}000$ ohms, and the current $I = \frac{E}{R} = \frac{110}{11{,}000} = 0.01$ ampere. If the voltmeter is properly calibrated, its reading will be equal to its resistance times the current flowing through it, in this case 10,956 × 0.01 = 109.56 volts, or a difference of only 0.44 of a volt less than line voltage. This 0.44 volt is expended in the lamps, consequently it is evident that the effect that the lamps would have upon the reading of the instrument could scarcely be detected on the scale. On the other hand, each lamp has 220 ohms resistance and when connected across a 110-volt circuit would take 110 ÷ 220 = 0.5 ampere, or 0.5 × 5 = 2.5 amperes total current for the group to make them burn at their normal brilliancy; but when connected in series with the voltmeter, only 0.01 ampere flows through the lamps, therefore they will remain dark, on account of the high resistance of the instrument being in series with them.

Ancient Conception of Heat

The early-day theory regarding heat was that it was a material substance, a "subtle imponderable fluid" that was named "caloric." One of the chief constituents of any substance that would burn was supposed to be "phlogiston," and therefore if a substance burned completely or nearly so, it was said to be a pure or nearly pure "phlogistate," and when burned it became "phlogistated."

This theory was proved by melting a given weight of lead and keeping it in a molten state, skimming the surface as fast as a film appeared on it. When all the lead had been so converted into what we now call lead oxide, it was found that its weight was greater than the original lead—therefore phlogiston (heat or fire) had entered the metal, the weight of which was the increase in the weight of the substance. To further prove this theory, it was found that heating this phlogiston-impregnated substance in the presence of or mixed with powdered charcoal reconverted it into metallic lead—the phlogiston was driven out. We now know that it is oxygen from the air that attacks the lead when melted and forms lead oxide, and that when the lead oxide is heated with charcoal (carbon), the charcoal will rob the lead of the oxygen, because of the greater affinity of carbon and oxygen than lead and oxygen, leaving metallic lead again.

You must buy or pay—buy a Liberty Bond or pay Germany. The $100 Bond is the cornerstone of Liberty.

Coöperation of Public-Service and Isolated Plants

By IRA N. EVANS

A solution of universal application of the old problem of "buying vs. producing current." Coöperation will bring mutual profit, conserve coal and reduce investment for equipment.

THE generation of power in conjunction with heating by exhaust steam has become less profitable in many localities, due to the effort of public-service companies by low rates to control the business at a questionable return to themselves. Making the generation of current seemingly unprofitable for the isolated plant and in some cases taking over the business, still leaves the heating. In numerous instances these heating plants have grown to large proportions. Whether large or small they duplicate to a great extent the power requirements of fuel, labor and unavoidable boiler wastes.

It is a well-known fact that with the most improved methods and equipment only about 15 to 20 per cent. of the heat of the fuel is recovered in current when generated by steam, and 85 per cent. passes up the chimney or into the condenser cooling water. On the other hand, the isolated plant uses 60 to 70 per cent. of the heat of the fuel in the heating system and could easily recover the relatively small percentage convertible into power with practically little or no increase in the total fuel used, provided the functions were properly coördinated.

MUTUAL PROFIT IN COÖPERATION

In large industrial plants it is possible to recover all power convertible from the heating fuel by coöperation with the public-service company. There would be mutual profit, conservation of fuel to the community, and the central station would maintain control of the business.

Suppose an industrial plant used 1000 hp. in high-pressure boilers for heating in zero weather and purchased all power used from the public-service company at a flat rate of approximately 1c. per kw.-hr. The heating system would have a condensing capacity of 34,000 lb. of steam per hour in zero weather, and at least 3400 lb. of coal per hour would be burned and paid for in any case. Suppose a turbo-generator of, say, 1000-kw. capacity were installed between the heating system and the boilers and the current metered back continuously night and day into the public-service mains during the period that heating was required. The heating system would be hot water under forced circulation with the exhaust heater of the heating system functioning as a condenser for the turbo-generator.

At about 34 lb. per kw.-hr. and atmospheric exhaust, 900 kw. could be recovered from the fuel burned under the heating boilers, and by varying the vacuum on the heater, the steam rate on the turbine could be lowered as the requirements of the heating system were reduced by the rising outdoor temperature. In this event there would be a constant power-load recovery throughout the heating season, night and day, at a maximum power factor. If 100 kw. were deducted for circulating pumps and plant apparatus, the remaining 800 kw. could be delivered continuously into the public-service mains by utilizing the isolated plant's heating boilers and fuel.

Records of the Weather Bureau show 3782 hours during nights, Sundays and holidays when, in the average plant, heating is required and the power is inoperative. There are 2050 hours during days in the heating season when power is required, making a total of 5832 hours. Consequently, if a turbo-generator of proper size were installed in the heating plant previously mentioned, there would be a net power recovery of 5832 hours × 800 kw. = 4,665,600 kw.-hr. At 1c. per kw.-hr this would amount to $46,656 for the season. Allowing $100 per kilowatt as a war-time price to cover the installation of superheaters, generating and heating equipment, interest and depreciation aggregating 10 per cent. would amount to $10,000. Extra coal over heating requirements at $5 per ton would cost $7125 and supervision and supplies should not exceed $2500, leaving a balance of $46,656—($10,000+$7125+$2500)=$27,031 to be divided as mutually agreed.

If the isolated plant were supplying its own power independently of the public-service company, it would have to expend from one-half more to double the amount for equipment to guard against breakdown, and during day periods in the heating season would operate only 2050 hours, which would mean a net recovery of 800 × 2050 = 1,640,000 kw.-hr. This is less than one-half of the previous saving.

FUEL CONSERVATION EFFECTED

If the public-service company generated current on 2 lb. of fuel per kilowatt-hour, the conservation of fuel to the community in the heating season would be 4,665,600 × 2 ÷ 2000 = 4665 tons. It is anticipated that the plant would purchase current on the same basis as before, depending on the rebate from current returned to the mains for its profit. It would depend on circumstances and the relative economy of the public-service plant and the turbine under vacuum, whether the machine would be operated during the summer months. No duplicate machinery would be necessary in the isolated plant, as in case of accident the load could be carried for the time being by the central plant, as the unit in the plant would function as part of the public-service company's equipment.

This method of operation would reduce the load on the central station at night and would add to the idle equipment. It will be found, however, that the number of plants available in any one district would be comparatively few and their capacities aggregate a small portion of the night load of the public-service station. They would furnish a source of cheap current during those periods, and as the public-service company has the mains and the only market for the current at these hours, it would have control of the situation.

The period of operation of the turbo-generator, 5832 hours per year, would be greater than that of the large public-service machines operating on a typical industrial-load curve. Where the load on the public-service station is heavier in winter than summer, it would be an advantageous arrangement if the isolated-plant turbine were discontinued during the summer.

It is the writer's belief that this is the most economical and efficient method of handling the isolated-plant problem, and it is applicable to any part of the country for heating plants having over 500 hp. in boilers.

For the assumed case, Table I gives the hours for each 10-deg. period of outside temperature, the steam required for heating, the vacua that would be possible with the water temperatures required and the corresponding steam rates for the turbine. With these data it is easy to figure the total steam and the kilowatt-hours recoverable. The column heads indicate the method. As an interesting comparison Column X gives the electrical energy recoverable from the heating steam by means of a noncondensing reciprocating engine. In moderate weather the noncondensing unit is outdistanced in the ratio of two to one.

The boilers and fuel are purchased and operated in any case by the owner of the heating plant, and no change in this arrangement is contemplated. As will be shown from concrete cases, a saving of fuel will be effected for the owner over the previous method of heating by low-pressure steam sufficient to pay for the changes and modifications of the heating system to successfully operate as a condenser for the turbo-generator.

Note—Column IX = Col. V ÷ Col. VIII; Col. X = Col. V ÷ 35; Col. XIII = Col. XII − 100; Col. XV = Col. XII × Col. XI × Col. XIV; Col. XVI = Col. XV × Col. IV; Col. XVII = Col. V × Col. IV

The ordinary low-pressure steam system is a good condenser of steam, but at pressures at the source all above atmosphere, and this makes it inefficient as an adjunct to power generation. The hot-water system is adapted to use steam at pressures above and below atmosphere. At 3 lb. back pressure it will give an average water temperature of about 200 deg. for zero weather. With a range of about 80 to 120 deg. in moderate weather it will do the heating and still allow a vacuum of 26 in. on the turbine. The arbitrary control of the vacuum regulates the temperature of the heating medium and determines the steam rate on the turbo-generator. When the power and heating loads balance in zero weather it is a fortunate coincidence that the saturated steam used by a turbine decreases with the improving vacuum in almost exact proportion as the heating demand is reduced by the rising temperature. Use of superheated steam upsets the equilibrium somewhat, and it is advisable to use a little additional coal in moderate weather to keep up the power output.

As the turbo-generator uses 100 per cent. more steam under atmospheric pressure than under high vacuum, it is uneconomical to operate in conjunction with a steam-heating system utilizing the exhaust steam for heating. In most cases, therefore, when the question of combining power and heating in the isolated plant arises, a low-pressure vacuum steam system is assumed, which compels the use of reciprocating engines, slow-speed generators and noncondensing conditions the year around, with the result that the space occupied and first cost are excessive and the financial return less favorable. The constant steam rate on the noncondensing reciprocating engine with the widely varying heating requirements causes the recovered power load to range from 100 per cent. in zero weather to less than 50 per cent. in warmer periods, while the variation in the turbine steam rate permits greater recovery. This is shown in Table I.

In a new plant the hot-water system can be installed at no greater cost than a steam system and with no more heating surface if properly designed. The regulation of the vacuum for maximum power will at the same time compel regulation of the heating medium with the outside weather, giving a constant interior temperature. There will be a saving of 25 to 30 per cent. in the heating steam over the constant-temperature low-pressure steam-heating system, or more than sufficient to allow for additional fuel to raise the steam pressure for power purposes. The power operation will give an opportunity to utilize for feed-water purposes all steam from auxiliary pumps of the heating plant, which is generally wasted due to the high temperature of the return condensation.

In ordinary low-pressure steam plants using steam at 5 lb. pressure, the boilers are operated at from 100 to 140 lb. pressure and steam is supplied through a reducing valve. The total heat per pound at 140 lb. pressure is 1194 B.t.u., and the temperature 361 deg. F. If the steam is reduced to 5 lb. pressure, the temperature is actually 308 deg., showing that at this pressure the steam is superheated 80 deg. The corresponding pressure for the temperature is nearly 61 lb. gage. As the loss of heat from pipe surfaces is proportional to the temperatures and not the pressures, the heating system is actually operating at a temperature corresponding to 61 lb. pressure instead of 5 lb. and will use more steam. This accounts for the frequent statement of many engineers that they find little difference in fuel if they operate the engines and heat with exhaust steam or heat by live steam at reduced pressures, the power costing nothing. No one would wonder at an increase in fuel if told the system was operated at 60 lb. instead of 5 lb. pressure, and this is virtually what happens. The heat all goes into the building, but is generally lost in mains and nonessential places.

This is obviated with the hot-water system owing to the use of the heaters: one for live steam with gravity return to the boilers for use when the engines are inoperative, and an exhaust heater that utilizes the exhaust steam at atmospheric pressure and below. The water is passed through both heaters in series, and all steam at whatever pressure is converted to water temperatures always the same for the same outside temperature. The steam is piped a comparatively short distance.

A CONCRETE CASE IN POINT

In substantiation of the previous statements the writer has a concrete case and approximate conditions in two other plants to offer. The plant first mentioned is heated by live steam reduced to 5 lb. pressure and the others already have forced hot-water heating systems and purchase current. The steam-heated plant operates 1600 hp. in Stirling boilers at 150 lb. pressure. The second plant is shut down in summer, but during the heating season operates 800 hp. in boilers. The third plant will have 2000 hp. in boilers, a portion to be operated throughout the year. Table I will serve to show the possibilities in the first plant if the steam system were changed to hot-water heating and the plant operated as previously suggested. Inasmuch as there are turbine feed pumps and engines to drive the forced-draft fans, the additional fuel for the higher pressure and for heating the feed water will be practically nothing, although the factor of evaporation is taken from the temperature of 212 deg. in each case to 175 lb. and 100 deg. superheat. Table II summarizes the possible saving in each of the three plants.

In the three plants there is recovered from heating steam 11,078,600 kw.-hr. At 2 lb. of coal per kilowatt-hour in the central station, this represents 11,078 tons of coal per season. In the first plant there is a net saving of 2000 tons of coal for power and heating combined over heating alone, and in the other two plants an addition of 1250 tons is required for power over heating. The net saving to the community is 11,828 tons of coal, which at $5 per ton amounts to $59,140. At 0.95c. per kw.-hr. the recovered current is valued at $105,247, which is nearly 60 per cent. of the total expenditure.

In plant No. 1 the actual fuel purchased for heating in 1915-16 was 9000 tons, or 2000 tons more than required to heat by hot water and recover 4,665,600 kw.-hr. The difference in fuel pays a large return on the investment required for changing the heating system. In this plant two large air compressors are operated the year around and only part of the exhaust is used for heating on a near-by building. High-pressure steam for heating is reduced from 140 to 5 lb. through a reducing valve. In summer 20 tons per 24 hours is used to operate the plant Sundays and holidays when no work is accomplished. The turbine feed pump and forced-draft fan engine practically exhaust to atmosphere, as all condensation is returned to the boiler room at a comparatively high temperature. If vacuum were carried on a turbine unit for power, there would be ample exhaust from auxiliaries to heat the feed water to 200 deg. at least.

Plant No. 2 has a hot-water plant and would require only a 350-kw. machine and the heaters changed to carry a vacuum on the turbine. The coal is not weighed and the boilers are operated below rating under less than 100 lb. steam pressure. Plant No. 3 has a hot-water heating system, 2000-hp. in boilers and a large noncondensing air-compressor plant operated throughout the year. Current is purchased for power and lighting and there is probably a total consumption of four to five million kilowatt-hours per year.

TABLE II. TYPICAL ILLUSTRATION WHERE LARGE SAVINGS ARE POSSIBLE

Plant No. 1		
Steam Heating, 1600 Hp. in Boilers		
Heating fuel as per record, 1915-16, 9,000 tons at $5		$45,000
Power purchased, 3,336,225 kw.-hr. at 0.95c.		31,694
Operating cost		$76,694
Cost changing heating to hot water	$60,000	
Cost generating equipment, 1,000 kw.	75,000	
Int. and dep., at 10 per cent. on	$135,000	$13,500
Power and heating fuel, 7,000 tons at $5		35,000
Attendance and supplies for 6 months		3,000
Gross cost		$51,500
Kw.-hr. recovered 800 × 5,832 = 4,665,600		
Surplus kw.-hr. 4,665,600 — 3,336,225 = 1,329,375 at 0 95c		$12,629
Net operating cost		$38,871
Net saving ($76,694 — $38,871)		**$37,823**
Plant No 2		
Hot-Water Heating, 800 Hp. in Boilers		
Int. and dep. on gen. equipment and heaters (10 per cent. on $21,000)		$2,100
Extra fuel for power over heating, 350 tons at $5.		1,750
Attendance and supplies, 6 months		2,000
		$5,850
Kw.-hr. recovered, 250 × 5,830 = 1,457,500 at 0.95c		$13,846
Net saving ($13,846 — $5,850)		**$7,996**
Plant No. 3		
Hot-Water Heating, 2,000 Hp. in Boilers		
Int. and dep. on gen. equipment (10 per cent. on $75,000)		$7,500
Extra fuel for power over heating, 1,100 tons at $5		5,500
Attendance and supplies, 6 months		3,000
		$16,000
Kw.-hr. recovered 850 × 5,830 = 4,955,500 at 0.95c.		$47,077
Net saving ($47,077 — $16,000)		**$31,077**

In plants Nos. 1 and 3 it would pay the owners to generate their own power independently, but the installation would have to be at least 1500 kw. instead of 1000 kw., with a corresponding expenditure and with little greater saving than would be attained by operating the heating boilers for power in conjunction with the public-service company.

The foregoing outline, if adopted in some form, will make the public-service plant stronger and more profitable and solve the question of unprofitable rates to large consumers who are shirking the responsibility of generating their own power and are actually wasting the community's fuel. The system could be adapted to office buildings having over 500 hp. in boilers by operating a turbine during the heating season to recover the electrical energy from the heating fuel, purchasing all current required above this amount in winter and buying all current during the summer months. This would also help solve the district-heating tangle, due to the high cost of fuel, but with this difficulty—the changing from steam to hot-water heating.

Exhaust Pits for Low-Compression Oil Engines

By L. H. MORRISON

Forms of exhaust pits are described, together with means for preventing accumulations of discharged oil and avoiding damage by explosions.

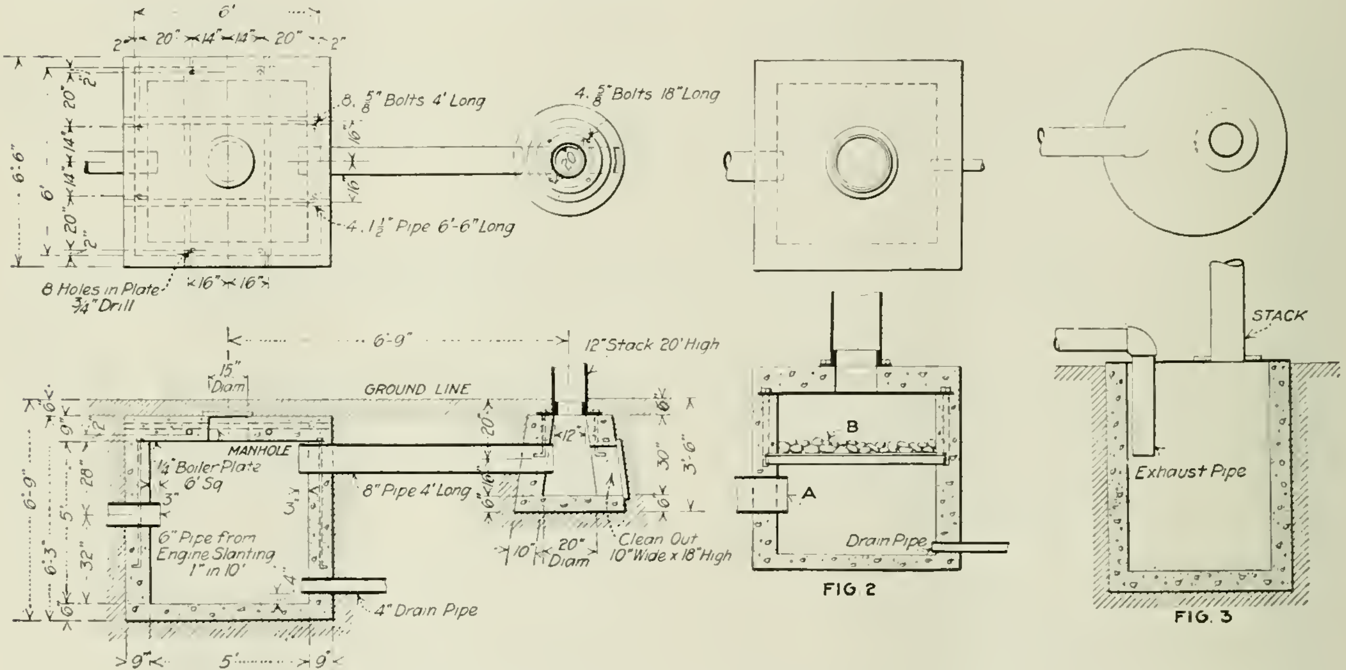
EVERY low-compression oil engine, no matter where it is installed, should be provided with an exhaust pit. It is the practice of some manufacturers to furnish a cast-iron exhaust pot, which is located close to the engine. While this assists in dampening the noise of the exhaust, it does not, by any means, take the place of a pit.

Low-compression engines, regardless of make, display a tendency to allow part of the fuel charge to blow out through the exhaust ports while it is in a liquid condition. This is especially noticeable when an oil having a heavy asphaltum base is used, because the cylinder temperature is not high enough to vaporize the heavier portion of the oil. The same objection frequently is raised against heavy fuel when the engine is operating on low loads. On low loads the temperature of the bulb or hot ignition device falls so low that it is unable to vaporize completely any of the fuel oils ordinarily used. As a consequence, some oil must enter the exhaust pipe. The same condition is often encountered when the governor and the injection nozzle fail to cut off the oil supply at the proper point.

If the discharged oil is trapped in an exhaust pot located close to the engine, it will accumulate until it is set afire. The exhaust is always at a high temperature, and frequently a flame blows through the exhaust ports and ignites this residue. Many fires, some of them serious, have resulted from the use of the exhaust pot or muffler.

To overcome the objection to the pot, a concrete exhaust pit should be constructed outside the building. It is a good plan to place the pit at least five feet from the building wall. Means should be provided for draining away the residue that accumulates in the pit. If the contour of the land permits, the drain should have an open end. If not, it should be run to a smaller pit and a bucket should be placed in this pit below the drain. In this way the residue will collect in the bucket and can be removed.

Fig. 1 shows a form of exhaust pit much used. It is provided with an extra exhaust-stack pit leading from the pit proper. While this is of assistance in deadening the noise, it is a refinement not actually required. Note should be taken of the reinforcement of the concrete. This will resist the ordinary strains to which the walls are subjected. It is necessary to use a manhole, both for access to the pit and for safety in case a violent explosion occurs.



FIGS 1 TO 3. FORMS OF EXHAUST PITS FOR OIL ENGINES

Another good form of pit is shown in Fig. 2. Here the exhaust pipe *A* enters below the layer of rock *B*, which is supported by old rails or iron bars and serves to deaden the sound of the explosions. Such a pit is well-nigh noiseless. It should be provided with a manhole in the side, below the layer of rock. This manhole can be fitted with a thin cover held in place by two small studs, so that, if a heavy explosion should occur, the cover will blow off and prevent damage to the pit.

Frequently a cylindrical exhaust pit like that shown in Fig. 3 is used. This, however, is not of good design, as it does not even deaden the noise of the exhaust. Furthermore, as it has no drain, the residue cannot be removed readily.

The pit should be so located that its top will be a few inches below the ground level. The exhaust pipe should be a size larger than the flange on the engine, in order to provide a free exhaust, and the pipe from the engine should slope down toward the pit, in order to drain well.

The exhaust stack from the pit should be considerably larger than the exhaust piping; for instance, if an exhaust pipe 8 in. in diameter is used, the stack should be at least 12 in. in diameter. Owing to initial cost it is customary to use a sheet-steel stack of from No. 8 to No. 16 gage. Corrosion in the stack is generally severe, and as a consequence the heavy gage is cheapest in the long run.

Large Single-Phase Transformers

Four of the largest single-phase transformers ever built were recently shipped by the Westinghouse Electric and Manufacturing Co. from East Pittsburgh, Penn., to a Southern power company. These units, one of which is shown in Fig. 1, are rated at 14,000 kv.-a. 60 cycles, and since they have a 25 per cent. overload rating, they have practically a 17,500-kv.-a. maximum capacity.

They will form a 42,000-kv.-a. bank, which, together with a spare unit, will make the preliminary installation to step up the voltage of the waterwheel-driven generators from 13,200 to 150,000, the highest transmission voltage used today. Power will be transmitted about 25 miles to an industrial plant, where it will be stepped down by means of a number of 7000-kv.-a. single-phase transformers of similar characteristics, ten of which have recently been built by the Westinghouse company.

Owing to the large size of the 14,000-kv.-a. units and the great amount of generating capacity that will ultimately be concentrated behind them and their need to be able to withstand the effects of momentary short-circuits, the shell type with the special end frames and bracing arrangement shown in Fig. 2 was selected. Structural steel for these parts was used throughout, because the strength of the various members can be depended upon to a much greater degree of certainty than with castings. The top and bottom ends of the coils are held against distortion by two heavy steel plates, each reinforced by four lengths of angle iron riveted to them and held together by four heavy tie-rods.

The tanks are made of heavy boiler plate, all seams being oxyacetylene-welded. A structural-steel base with wheels supports the tank. The high-tension terminals are of the condenser type protected by means of a number of porcelain rain shields to adapt them to outdoor service.

Some idea of the size of these units may be gained from the fact that their height measures 23 ft. 6 in. from the top of the high-tension terminals to the base, and each unit weighs complete with oil and fittings approximately 110,000 pounds.

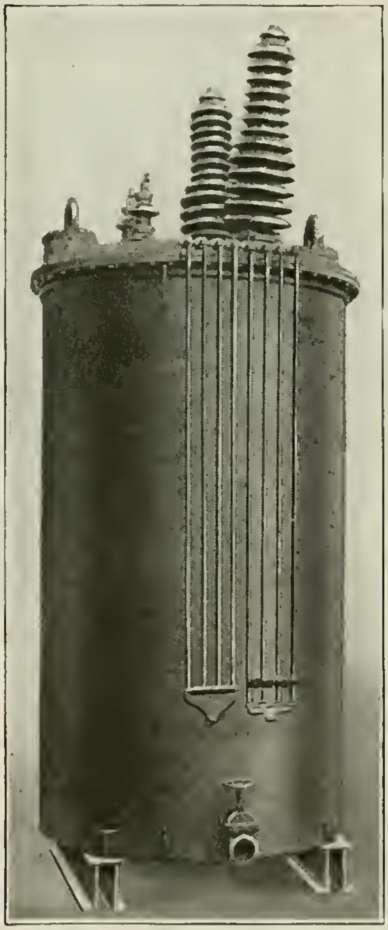


FIG. 1. TRANSFORMER COMPLETE

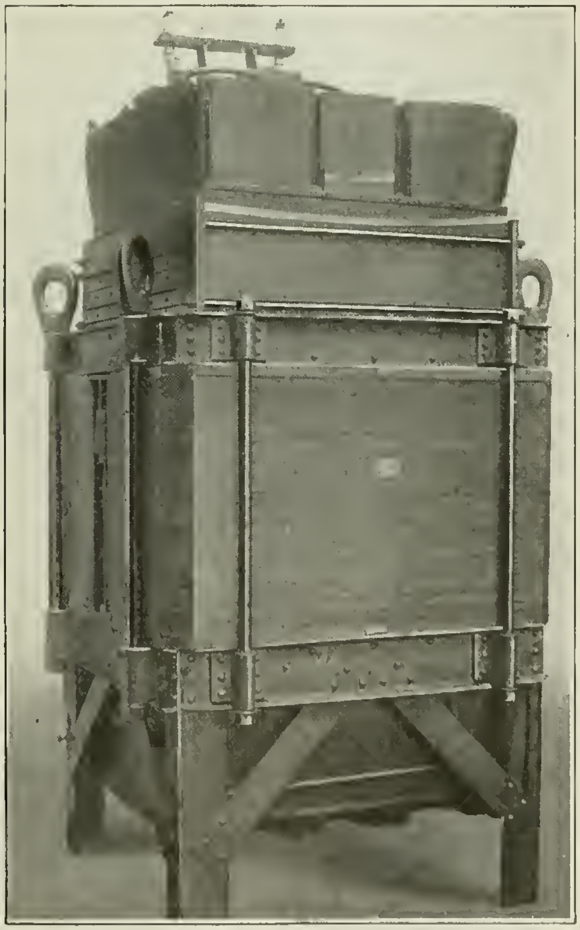

FIG. 2. CORE AND COILS OF TRANSFORMER ASSEMBLED

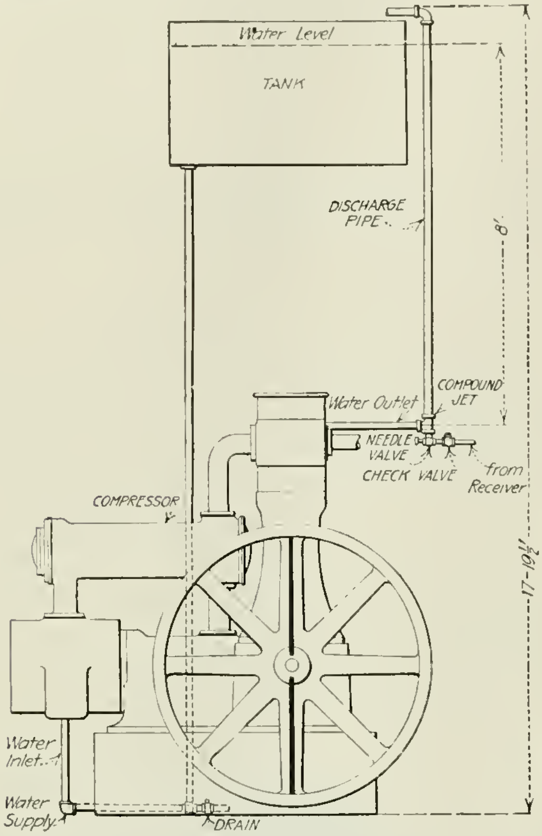
White Power in Italy

According to P. Lanino, an Italian authority who has recently published four volumes on "La Nuova Italia Industriale" (The New Industrial Italy), Italians in general have cause to be optimistic on the question of the utilization of water power. In 20 years, he points out, about 1,000,000 hp. of water has been harnessed, and it is estimated that from 2,000,000 to 6,000,000 hp. is readily available, while the potential horsepower ranges as high as 20,000,000. Within ten years 300 kilometers (186.5 miles) of railroad have been electrified, and plans have been prepared calling for the electrification of 2000 kilometers (1243 miles) more—one-seventh of the total mileage in Italy.

Air Lift for Compressor-Jacket Water

The accompanying illustration shows how the air-lift system of pumping can be utilized to form a simple and effective method of supplying cooling water to air-compressor cylinder jackets. A small tank is placed about eight feet above the compressor, which gives sufficient height to permit the water to flow by gravity through the jackets. Instead of using a pump for this purpose or for elevating the water to the gravity tank again, a needle valve or, still better, an air-lift mixing tube controlled by means of a pin valve, is placed at the base of the riser, just outside of the water-jacket discharge. This valve is connected by a small pipe with the air receiver, and a small amount of air is thus forced into the riser pipe, acting to carry the water from the cylinder jacket back to the elevated tank.



PIPING OF AIR-LIFT SYSTEM

The amount of water required depends, of course, on the size of the compressor. A 10 x 10-in. single-stage machine, having a capacity of 213 cu.ft. per min., would require about 5 gal. per min., and for this a 1-in. pipe would be sufficient.

This plan of automatic cooling water circulation, says *Mine* and *Quarry*, was worked out by George H. Richey, one of the engineers of the Sullivan Machinery Co. at Boston, who has placed it at several installations in New England, as a substitute for a small centrifugal pump driven by an electric motor. Excellent results are obtained, and the heat in the water is reduced to a considerable extent by the expansion of air in the riser or eduction pipe. The sketch shows the system as installed for a two-stage angle-compound compressor. It is, of course, even simpler with a single-stage machine. In the installations referred to, no trouble has arisen, and the system has kept the compressors properly cooled.

Blackstone's Roll of Honor

W. A. Eberman, chief engineer of the Blackstone Hotel, Chicago, has been a patriotic worker in the campaigns for the three Liberty Loans. To further subscriptions among employees of the engineering department of the hotel, he has instituted a Roll of Honor. As soon as a man signs up for a bond his name is entered in gilt letters on the board shown in the accompanying illustration. Its dimensions are about 4 x 6 ft., and it is mounted in the engine room in plain sight of the force. There is a border of red, white and blue; the frame is gilt and the roll is golden literally and in spirit as well, for 48 of the 50 men in the department have subscribed to the Third Loan and the other two have agreed to invest a definite sum in Thrift Stamps. The efficiency is 100 per cent.

In looking over the names there is a cosmopolitan variety of nationalities represented: German, Bohemian, Austrian, Belgian, Swedish, Russian, English, Irish and Scotch. All have shown their patriotism. Not one has failed to subscribe. It is a gratifying example of what can be done and is a leading suggestion to other large plants.

The Blackstone

At times nails and pegs are found extending from walls at face level to hold tools and clothing. Such projections make dangerous hazards when not in use, and they should be removed. Clothing should be hung in lockers, and firing tools should preferably be kept in racks.

Editorials

The Ultimate B.t.u.

THE central-station folks have been raising a considerable hullabaloo of late—to be particular, since the Fuel Administration has begun to ferret out the places where coal is going to waste—about the terrible inefficiency of the isolated plant in the generation of power. In the same breath they have been making considerable fuss over the wonderful efficiency of the central station as a power producer.

The point at issue between the two types of plants, so far as the Fuel Administration is concerned, is simply one of coal conservation, which may be expressed in another way as making a pound of fuel go just as far as possible in producing useful effects. Under this broader interpretation of the problem, the isolated plant has a strong case against its powerful opponent.

Observe what happens to a pound of coal in the central station. It goes majestically to the furnace on a chain-grate chariot, flares up in one swift burst of incandescence, and gives all its latent energy to a swirl of gases that sweep the boiler, caress the tubes of the superheater and are whisked away through the economizer to the chimney, while from the boiler flows that aristocrat of heat mediums—superheated steam.

The steam—thermal offspring of that pound of black, prosaic coal—rushes lightly through the main, enters the turbine, flirts daintily with the flying blades, and leaves, with its energy only slightly diminished, to give up all its remaining heat to the condensing water; and that condensing water, carrying with it about eight-tenths of the heat liberated from the stodgy pound of coal, goes merrily seaward to warm the fishes, who don't need warming and are totally ungrateful for the favor so graciously bestowed.

By contrast, see what happens in the isolated plant. The pound of coal is heaved unceremoniously through the fire-door by a member of the strong-arm squad, breathes its last on an old-fashioned herringbone grate, and passes its heat into a boiler that produces a slug of plain, ordinary wet saturated steam—the common garden variety discovered by Watt some decades ago.

That slug of steam eventually finds its way into the cylinder of an old-fashioned reciprocating engine, where it churns to and fro, spends a small fraction of its energy in generating power, and escapes clumsily and soddenly into the exhaust pipe, still holding in its keeping about nine-tenths of the heat it received from the pound of coal.

But no condenser yawns invitingly to receive it. That little trip through the engine was mere play. The real work is about to begin. A houseful of radiators waits to claim some of that exhaust steam for heating; some of it goes to a hotel kitchen to aid in cooking; some of it goes to a laundry, where it helps to heat water and dry clothes; a part of it enters the generator of an absorption plant and furnishes refrigeration for cooling and ice-making; and after all these varied interests are served, if there is anything left of that slug of wet steam—which there usually isn't—it escapes through an exhaust stack, a mere ghostly wraith, scarcely visible to the naked eye. Meanwhile, the steam that has done this work is a collection of streams of hot water that are collected, drained into a trap, and sent back to the boiler, carrying with them the last B.t.u. that can be reclaimed.

When it comes to utilizing the last heat unit in a pound of coal, the isolated plant for combined lighting and heating need not take off its chimney cap to any central station.

Launch a Blow in Defense of Liberty

ALL newspaper readers are familiar with the reports from Washington which interpret the weather map. We read, for example, that an area of high pressure is static over the Middle Atlantic States, or we learn that a "disturbance," originating in the far Southwest and centering for the moment over northern Texas, is moving rapidly northeastward and within forty-eight or sixty hours should bring us a violent and sustained storm.

From the German point of view our Liberty Loan campaign is just such a "disturbance," collecting the elements of its future fury thousands of miles away. Through the mysterious channels by which their arrogant leaders are kept informed of the activities of this land, the Germans learn of the gathering storm, and they watch its development with an anxious intensity second only to their keenness for word of the tide of battle in France. They know that as fast as these Liberty Bonds are converted into guns and munitions and put into the hands of American soldiers, the "disturbance" will move upon them with the inexorable force of a cyclone traversing a continent. And they know also that when it arrives it will beat against them, uprooting and sweeping away their defenses, with just that degree of violence which is imparted to it in the beginning by the will of its originators.

That is to say, it is the initial impulse which places limits to the force of any drive, and in the case of such an offensive as that just described the initial impulse comes from the patriotic hearts and pocketbooks of one hundred million Americans. If they respond to the challenge, each to the limit of his ability, eagerly, passionately, completely, the Germans will know that they are in for a cyclone such as only America can breed.

There is not an American among us who can afford to stand by and watch the launching of this tremendous blow for liberty without contributing to it his full share of patriotic frenzy expressed in cold cash. The money will come back increased with a bountiful interest, but that is not the main point for the investor; this lies in the opportunity it will give him to get in his particular jab against the barbaric enemy which, with all the vicious ferocity of desperation, is seeking to trample under foot our boys "over there," our Allies' boys, our Allies' fair lands and homes and liberties and, beyond them, our own. There isn't a man with a single minim of American blood in his veins today who wouldn't give his all to check the freshet of Boches on the western front. Here is his opportunity. Let him join the storm that sooner or later will set that appalling flood rushing the other way. Specifically, let him invest as much of his money in bonds of the Third Liberty Loan as he can spare from the necessary daily expenses of his existence.

Combustion and Furnace Design

WHAT is perhaps the most valuable bulletin on the subject of combustion and its influence upon the design of furnaces has been issued recently by the Bureau of Mines. A full review, together with remarks on this bulletin, appears elsewhere in this issue. Experience has taught that high boiler settings with great furnace volume have greatly improved combustion, but it is safe to say that most of us have not known fully the reasons why. We have known that stoker-fired furnaces of large volume have given far better mixtures of the air for combustion and the combustible gases than is obtained in the ordinary hand-fired setting. The bulletin corroborates experience which tends to show that, although engineers have carried the ordinary water-tube boiler settings to a height of twelve feet from the bottom of the front tube headers to the floor line, even this height, great as it is compared with practice of a few years ago, is not sufficient with ordinary settings to insure the most desirable conditions for commercially perfect combustion. It is interesting to note that the investigations of the authors of the bulletin show that there is a definite relation for each coal between the excess of air supply and CO_2.

The percentage of excess air that gives the best results in any steam-generating apparatus varies with the size of the furnace and the kind of fuel. In two furnaces burning the same fuel but having different sizes of combustion space, the one with the smaller space may receive more excess air for the best results than the one with the larger combustion space. Also, of two furnaces exactly alike in size but burning different coals, the one burning coal lower in volatile matter and oxygen gives better results with lower excess of air than is necessary for the best results in a furnace burning the coal higher in volatile matter and oxygen. This explains why in one plant the highest efficiency may be obtained with fourteen per cent. of CO_2 in the gases, and in another plant with only ten per cent. of CO_2. In other words, the investigation brings us much nearer to a general understanding of the reasons why the statement which claims that efficiency is always highest with the higher CO_2 may be questioned when applied to the usual boiler setting. It is likely true that if one could design a furnace to give a thorough mixture of the air for combustion and the combustible gases, maximum furnace efficiency would occur when the CO_2 was at a maximum; but in the usual boiler furnace we must depend in great measure upon an excess of air to obtain the best mixture of air and combustible gases under the local conditions. We direct particular attention to the pages of the bulletin which deal with the subject of soot formation. The authors point out that soot is formed at the surface of the fuel bed by heating the hydrocarbons distilled off from the volatile in the coal in the absence of air; it is not formed by the hydrocarbon gases striking the cooler surfaces of the boiler. It is pointed out that only a very small trace of the hydrocarbon gases ever reaches the surface of the boiler. In other words, the cooling surfaces do not cause or promote the formation of soot, but they merely act as collectors of it.

Pages 134 to 137, the last in the bulletin, are especially interesting. In these pages the authors point out that the volatile matter in soft coal may be distilled off and converted into liquid fuel for motor purposes, in which form it has a value from twenty to thirty times as great as that in the form of coal. As the supply of bituminous coal is enormous, the uses of the oil are practically unlimited and the margin of profit in the conversion is large. It would seem that the development of highly productive methods would be rapid. By itself the coke residue from such reduction plants would have considerable commercial value, and if its price were made equivalent to coal, it would doubtless find a wide market for house heating and steaming purposes. The authors say that vague reports from Europe indicate that after the war the world will be informed of some extraordinary developments in the utilization of bituminous coals in certain countries, and that these developments will be of pressing importance to American manufacturers. One notices that two or three different companies have been formed recently for the purpose of distilling the highly volatile matter out of bituminous coal, using the residue for steaming purposes, while the distillates are to be used for chemical and motor fuel purposes. *Power* has, from time to time, pointed out that some day it would be the chemist who would reveal to the public the wasteful manner in which the engineer uses coal by giving the people a truer conception of the intrinsic value of bituminous coal. This seems to be the beginning.

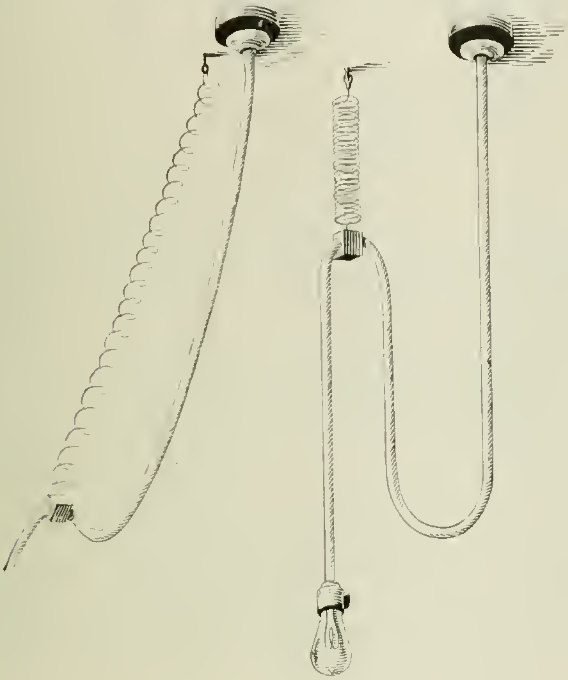
There is no doubt that the Fuel Administration's zone system for the distribution of bituminous coal will effect considerable saving in transportation and will, if entered into in the right spirit by the mine owners, dealers and the people, help to avoid such deplorable shortages as occurred last winter. That the country as a whole may be benefited some consumers must be inconvenienced. Many plants in Illinois, for example, long accustomed to the West Virginia low-ash, low-volatile coal, must now use the high-ash, high-volatile coals of Illinois. Consumers in Iowa, Kansas, Missouri and Nebraska, particularly, can no longer get the West Virginia coals, but must use the coals produced in their own districts. The whole Middle West and Northwest is thus affected. For these people many new combustion problems will arise. *Power* hopes soon to begin the publication of articles written especially to help these consumers solve such problems.

The engineering world is still waiting for the report of the committee of scientists who were to determine whether the Garabed should receive a laurel crown or merely a casket bouquet.

Correspondence

Handy Extension Lamp Cord

The illustration shows a drop-light arrangement that I have found very convenient for use in places where a light is needed for inspecting the interior of ice tanks and the like, and that at other times is available for general illumination. It consists of a spring taken from a shade roller fastened to a drop-light cord, which should be of suitable length so that the light will be lifted out of the way when not in use within the tank.



SPRING SUPPORT OR HOLDER FOR DROP LIGHT

St. Louis, Mo. **Arnold James.**

Fatal Explosion of Home-Made Boiler

In the local morning paper several days ago I saw in large headlines, "Boiler Explodes, Frozen, Kills One Man." Anxious to learn the details of the case, I went, in company with another inspector, to the scene of the accident. How the writer of the article knew that the boiler was frozen still puzzles me, for we could not obtain enough information from our investigation to arrive at such a conclusion, as not a particle of the boiler proper could be found. The fire-door frame was found about a block away, and there was no one about the plant at the time of the accident except one young man who, unfortunately, was instantly killed.

A boy about 16 told us he had seen the boiler installed, and upon questioning him regarding its design, he said that they had taken an ordinary kitchen hot-water tank suspended it with iron bars, built a furnace of rock under it and used it to produce steam to sterilize milk cans and for other cleaning about the dairy. As to whether there was a steam gage, water column or safety valve, no one knew, but I doubt it. Judging from the damage done, there was a tremendous pressure on the boiler at the time of the explosion. The building was completely wrecked, and rock from the setting was scattered over a radius of five hundred yards; and one of the fireman's feet was found two hundred yards from the plant and in almost the opposite direction from that in which the body was hurled.

This boiler was within the city limits and should have been inspected by the city inspector. It is stated on good authority that it had been in service for several years, but the city had no record whatever of it or it probably would have been eliminated. It appears to me that the life of this promising, able-bodied young man was lost because the people of the State of Washington have not seen to it that laws under which steam boilers must be properly designed and operated are enacted and enforced.

By far too many of us say nothing until after such an accident and then jump at the conclusion that the boiler was frozen or that the fireman was to blame for various reasons.

I have inspected boilers in eight states, some of them having no boiler laws, and the probability, in my opinion, is that more lives will be lost if all states do not promptly wake up to the fact that there should be standard boiler designs, compulsory inspection and licensing of engineers and firemen. **R. S. Hart.**

Alternating Current Cannot Cause Corrosion

The only effect of eddy currents that would cause the water-pipe joint to corrode as mentioned in the article "Lighting Circuit Caused Water-Pipe Joint to Corrode," in *Power*, Feb. 5, would be of a thermal nature. Such effects require that a large current be induced in the pipe, which in turn requires that the inducing circuit have considerable ampere turns and high frequency. This is true since the induced currents are proportional to the induced potential and the pipe resistance, the former being dependent on the flux changes.

The small amount of energy involved in a lighting circuit would at once eliminate it as a cause of corrosion. It is highly probable that stray direct current from a railway is entering the building through the water line and that the trouble is due to a high resistance joint at the point of corrosion. If electrolytic action is due to an electric current, then it must be direct current since an alternating current will not cause such action. (See Bureau of Standards "Technologic Paper" No. 72.) **H. E. Weightman.**

Broken Cast Piston Repaired

The piston of a large vertical engine had a hole "punched" in it when the "keeper" key, holding the nut in place on the rod broke and got over into the clearance space. The engine was urgently needed and had to be repaired as quickly as possible. Welding would necessitate heating the entire piston to some extent and might distort it. It was therefore decided to "sew" the piece back in. We drilled and tapped holes along the crack and put in ½-in. cap bolts and sawed the heads off. One bolt overlapped the other so that they could not unscrew and work out. The job was completed in a short time and was entirely satisfactory. **George H. Diman.**

Static Electricity from Gasoline

In the issue of Jan. 22, page 130, D. R. Gibbs states that gasoline flowing from a spigot into an ungrounded can will produce sufficient static electricity to ignite itself. This will also occur if the liquid used under the same conditions is benzine or naphtha.

In the manufacture of paints and the grinding of pigments, where the solvent or vehicle is naphtha, gasoline or turpentine, the ignition of the liquid is liable to occur, especially with high-speed apparatus, and I have known fires to be caused by an operator touching the metal tank sides with a steel scraping knife. Grounding the apparatus is not always a preventive for if the tank be of considerable size its entire area may become charged and act as a storage of low potential, and there may not be sufficient difference of potential between it and the earth to cause discharge. Grounding is, as a rule, satisfactory in conducting to earth a static discharge where a considerable difference of potential exists; as, for example, in a fast-traveling belt.

In theory the earth is regarded as at zero potential, but in practice it is claimed that with a difference of less than 4000 volts potential grounding static discharges is ineffective, and other means are resorted to, as follows: Humidification will so dissipate the static charges that they will not build up sufficiently to produce sparks hot enough to raise even inflammable gases to the ignition point. Humidification may be produced by a steam jet, or in the absence of steam, water sprinkled around will produce enough moisture to secure relief. If humidification is objectionable, and it is in many of the processes of manufacture, circulating currents of air, preferably hot, will be found advantageous.

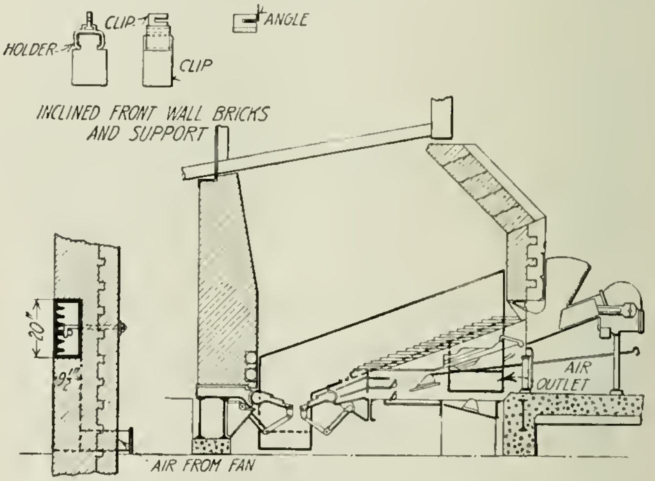
In printing-press work and where heavy, fast-moving machinery is employed, it is sometimes necessary to install a static neutralizer. This is a device that produces an alternating-current field, therefore having both positive and negative impulses. A static charge of positive sign is thereby neutralized by an impulse of opposite sign as generated by the neutralizer, consequently a static charge of negative sign is neutralized by one of positive value. This device is on the market and is used by many industries. **Mathew King.**

Passaic, N. J.

Ventilating the Side Wall Was Unsuccessful

One of the principal sources of annoyance to all stoker operators is the tendency of the clinker to stick to the side walls, which cuts down the available grate area and causes injury to the bricks when cleaning the fires.

The method illustrated was tried in conjunction with the Westinghouse stoker under a 250-hp. B. & W. type boiler, the setting being arranged as shown in the illustration. The total air for combustion was brought in from the outside of the setting underneath the boiler-room floor and conducted up along the side walls in the box as shown and finally discharged underneath the stoker. The three sides of this box were made in one casting, while the cover was made in three sections. To increase the heat-absorbing surface of the cover it was constructed as shown. The covers on the box were made of a good grade of cast iron.



HOW THE SIDE WALLS WERE COOLED

When this method was applied and the boiler put in operation, trouble was discovered almost immediately with the cover plates burning through. Increasing the velocity of air through the boxes did not remove this difficulty, and finally the whole plan was abandoned.

The method of supporting the brick in the inclined front wall is also shown. This method was satisfactory.

Pittsburgh, Penn. **L. B. Breed Love.**

Material for Dump-Plate Bearing Bar

I have noticed, in articles in recent issues of *Power*, several references to the operation of inclined underfeed stokers. One thing essential to the successful operation of these stokers, or in fact any of the ram-type stokers, is the removal of the clinker that forms on the side wall of the furnaces.

Some of the coal shipped these days contains a high percentage of ash and clinker-forming material which accumulates on the side walls of the furnace. This formation is sometimes so hard that it is necessary to let out the fires and to cut the clinker loose with pickaxes and bars. If it is allowed to accumulate, great strain is thrown on the ram-feeding mechanism, causing breaks and compelling frequent repairs.

The bearing bar under the dumping grates, which supports the grate sections, is regularly supplied in $\frac{3}{4}$ x $2\frac{1}{2}$-in. wrought iron, which sometimes bends under the heat coming from the recently dumped ashes. I have been using sleigh-shoe steel for making these bars, as it is slightly higher in carbon than the stock bars, making it stiffer under heat.

I think these bars should be made of cast iron about $1\frac{1}{8}$ in. thick and 6 or 7 in. wide with holes properly spaced cast in for the cotter pins which hold each grate bar. It also pays to watch the hand-operated shaking extension grates to see that no ashes or clinkers get under them to make them unhook the supporting shaft and burn the ends in the fire. H. G. **Burrill.**

Herkimer, N. Y.

Nut-Lock Plate

There are many ways to lock or secure nuts against slacking back, and the "lock plate" shown in the illustration is submitted, adding to the collection. The slot at *A* should be cut to within one-fourth inch of the bolt hole, and when the plate is on and the nuts up solid, the ear or tab is bent up, as shown at *B*, with a blunt chisel and a hammer. C. H. **Willey.**

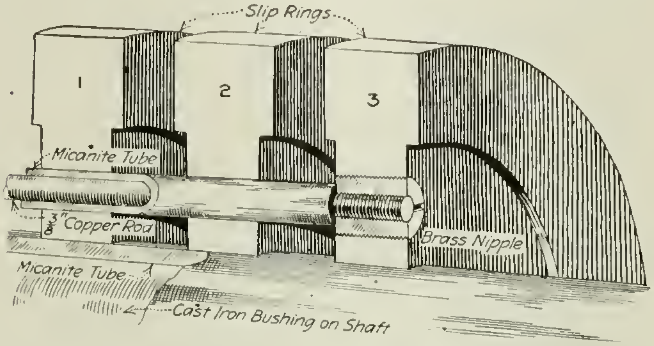
Slip-Ring Insulation Repair

The micanite insulating tube around one of the conductors to the outer slip, or collector, ring on one of our 250-kw. Westinghouse rotary converters in a traction substation broke down under the edge of the middle slip ring, resulting in a dead short-circuit across the two rings. The rings and conductors were not damaged much as the high-tension oil switch had only a small time lag, but the insulating tube was practically destroyed.



INSULATION ON CONDUCTOR TO SLIP RING RENEWED

To remove the rings and replace the insulating tube is a big job as the cast-iron bush with all three slip rings and the conductors are assembled together before being placed on the shaft; besides, outside of the bearing on this machine there is a small rotor and slip rings for the synchronous booster which forms part of the combined set. It looked as if there was no other way but to send the armature back to the makers for repair, but this would have been a difficult job in any event and unusually so in this case since the machine is installed under a gallery with very little headroom. Besides, conditions due to the war make the smallest repair take six months or more to get through the shops, so we decided to undertake the job ourselves.

The copper conductors, four to each ring, are screwed tightly from the inside into their respective rings, and there is just room enough to screw them out clear of the ring before they foul the armature spider. As the insulation in the rings 1 and 2 and around all four conductors to the outer ring (3) was badly charred, they were screwed out and the holes in ring 3 were enlarged by means of an adjustable reamer until the regular insulating tube would just pass through and into rings 2 and 1. The holes in 3 were then tapped out with a taper pipe tap that happened to be the right size, four brass nipples were turned, threaded and screwed in and the inside bore was a good fit on their respective rods. New lengths of insulating tube were then cut and placed in position and the rods and nipples screwed tightly home. The whole connection was as solid as when new. No special tools were made for the job except a piece of flat steel cut to fit the slots cut in the nipples, across the outer end, by means of which they were screwed in, as an ordinary screwdriver was too narrow.

The job was finished and the machine on the line again the next day at noon, being out of commission 27 hours—and the repair shop was two miles away from the substation at that. D. S. **Regan.**

Yorkshire, England.

An Electrical Phenomenon

I have read with much interest the article by H. S. Whiteley, "An Electrical Phenomenon," published in *Power*, Feb. 12. Similar phenomena may frequently happen, but it is not so often that they are observed, and it is very seldom they are reported and described.

The electrical effect observed was a discharge of blue sparks of static electricity produced by the friction of dry steam slightly superheated, passing through cold dry air at a high velocity, this discharge taking place where the expansion of steam was visible. Considering these phenomena from the viewpoint of the electron theory, which ascribes an atomic structure to all electrical charges, may be of interest.

When a very fine spray of water is directed on the plate of an electroscope, the leaves diverge, showing that the plate is electrified by the spray. The charge on the plate is positive and the air around the spray negatively electrified. In fact, whenever there is a splashing of water, electrification results, the two kinds of electricity being separated. Such electrical conditions can exist, for instance, at the foot of a waterfall, and it can be shown that the water is positively electrified and the air negatively. However, the kind of water and certain impurities it may contain have a decided influence upon the amount of electrification produced. It has been shown that when a drop of water is broken up into a spray while suspended in the air, the water becomes positively electrified and the surrounding air negatively. Hence, any process by which drops of water are broken up into a spray, whether by clashing against one another or in other ways, constitutes a potential source of electricity, and as soon as the strength of the field is large enough, a discharge takes place.

A few words regarding the separation of the electricities, namely, the positive electrification of the water and the negative electrification of the air:

A water molecule consists of a nucleus around which electrons are rotating. There is only one kind of electron, and this has a mass of $\frac{1}{1800}$ that of a hydrogen atom and carries a constant charge of negative electricity. The water nucleus, on the other hand, is positively charged. The two charges are equal in magnitude but opposite in sign, so that a water molecule is electrically neutral. To charge a water molecule positively means, therefore, that one of the electrons which it contains is taken out of it.

Now, when water or vapor molecules collide with the molecules of the air, electrons are pushed away from the water molecules, which by loosing electrons keep only their positive charge; namely, the charge of their nucleus. A detached electron, on the other hand, unites with a molecule of the air and then revolves about this air molecule. But when such an air molecule, which has taken on another electron, comes into contact with or near to a water molecule that has lost an electron, the formerly detached electron goes back to the water nucleus, thus establishing electrical neutrality. It is just this establishing of the electrical neutrality that we see in the form of a spark or a silent electric discharge.

A molecule that has lost or gained an electron is called an ion. A gaseous ion, in our case a water-vapor ion and an air ion, has the power of attraction through which a number of molecules that are not in the ionic state are collected around an ionic or electronic center. This fact corresponds to the observation of Mr. Whiteley that the discharge took place where the expansion of steam was visible.

By velocity measurements it has been shown that the ions in air at atmospheric pressure consist of single charges (electrons) associated with about 20 to 30 molecules of oxygen or nitrogen.

Discussion of Turbine Wreck

Allow me to comment on the wreck of the 35,000-kw. turbine of the Boston Elevated Ry., an account of which appeared in the issue of Mar. 19, page 390. At the outset let me give due and generous credit to the maker and his engineers for the prompt and frank publication of some of the details. It is just ten years ago that a 10,000-kv.-a. waterwheel generator, designed by the writer, who was then chief engineer of the electrical department of Allis-Chalmers Co., was destroyed during an overspeed test at Niagara Falls. The experience served as a most remarkable object lesson, with the result that no accident of a similar nature has occurred during the last ten years on machines with which he has had anything to do. This justifies an optimistic view in regard to the future of single-cylinder turbines of the impulse type, if the lessons from this accident are properly utilized.

The editorial remarks are judicious and fair. The disks are not the weak element. A disk construction for the largest types of turbo-generators has been developed that has marked an important advance in electric-generator design. The weakness lies in the method of holding the blades and in the distortion of the diaphragm. The use of cast steel would diminish distortion, but rotation of the diaphragm due to seizing on the shaft must be forestalled, as no material at these high speeds could resist the stresses in a disk shaped as the diaphragm is. This leads to the consideration of the advisability of greater clearance with this type of construction.

Power has rendered a public service by the publication of this accident; let us hope that this policy of frankness will find imitation in other quarters.

B. A. Behrend.

Boston, Mass.

Tamarack Mills Power Plant

I have read with much interest the article in the Mar. 26 issue of *Power* on the Tamarack Mills power plant, and would like to call attention to an error which I think should be corrected. It is stated that "the management got a price of 92c. per barrel of 42 gal. of oil delivered." This is not correct, the price actually being $1.15 per barrel delivered.

The price you give is near that which this company is paying on their fuel-oil contract for the Jenckes Spinning Co. mill, which contract was made in 1915, and it is worthy of note that after operating with oil for a year and a half, they were willing to pay over 20 per cent. more for their oil on the new contract.

Engineer, Mexican Petroleum Corp.

Inquiries of General Interest

Small Bypass Around Main Stop Valve—How can water-hammer shocks be prevented in a 6-in. steam line when the stop valve is opened very slowly and the line is drained at the discharge end through a 1¼-in. drip connection? T. P.

The line should be warmed up by means of a small bypass to control admission of steam more gradually. This will also permit of easier and safer opening of the main valve by equalizing pressure on its opposite sides.

Effect of Rocker Out of Plumb—If the rocker-arm of a Corliss valve gear oscillates ¾ in. more to one side than the other of a vertical position, what effect would it have on the operation of the steam valves? J. L.

With a rocker-arm and connections of usual length, the difference of oscillation would make no appreciable difference in adjustment or operation of the valves, provided the oscillation of the wristplate was the same on each side of the center.

Blistering of Boiler Shell—What causes blistering of a boiler shell? W. R. B.

Blistering is separation and puffing out of layers of the material that have not been thoroughly welded in the process of manufacture. When the shell is heated or cooled, the different rate of expansion or contraction causes the layers to separate. When blistering is confined to a very thin surface skin, its effect on the strength of the plate may be unimportant, but if the scaling-off process continues after the outside skin has been removed, it is an indication of defective structure of the material that may seriously impair the safety of the boiler.

Required Size of Steam Header—What should be the size of a main steam header where the sizes of pipes from five boilers are respectively 4, 5, 6, 6 and 8 in.? B. F. S.

Ordinarily, the size would be taken of an area equal to the sum of the areas of the feeders or the size of header would be

$$\sqrt{4^2 + 5^2 + (2 \times 6^2) + 8^2} = 13.3$$

or, nominally, a 14-in. pipe would be used. But for the same pressure the flow of steam in pipes of different diameters is as the square root of the fifth power of the diameters and, calling the required diameter d,

$$\sqrt{d^5} = \sqrt{4^5} + \sqrt{5^5} + 2\sqrt{6^5} + \sqrt{8^5} \text{ or } d =$$
$$\sqrt[2.5]{4^{2.5} + 5^{2.5} + (2 \times 6^{2.5}) + 8^{2.5}} = 11.47 \textit{ in. diameter}$$

and a header of 12-in. pipe would answer.

Valve Travel Unaffected by Diameter of Eccentric—Will the valve travel of a slide-valve engine be affected by reducing or enlarging the diameter of the eccentric? J. B.

It would not, because the eccentric is the exact equivalent of a common crank arm in which the crankpin is sufficiently enlarged to include the shaft, so it may be placed anywhere along the shaft. The valve travel depends on the length of the arm or the distance from the center of the shaft to the center of the eccentric, commonly called its eccentricity; and just as the length of stroke with a crank is independent of the diameter of the crankpin, the length of valve travel is independent of the diameter of the eccentric.

Kilovolt-Amperes and Kilowatts—What is the difference between kilovolt-amperes (kv.-a.) and kilowatts (kw.)? W. C. L.

Alternating-current machinery and systems, excepting induction-motors, are usually rated in kilovolt-amperes (kv.-a.) and not kilowatts (kw.). In a single-phase system kv.-a. = volts × amperes ÷ 1000; in a two-phase system kv.-a. = volts × amperes × 2 ÷ 1000; and in a three-phase system kv.-a. = volts × amperes × 1.732 ÷ 1000. In all cases, kw. = kv.-a. × power factor. Kilovolt = amperes is frequently termed the apparent power, and kilowatts is called the true power, or load on an alternating-current machine or circuit. The term kilovolt-ampere is never used in reference to the rating of direct-current systems.

Wetting Down Fine Coal—In hand-firing is there advantage or disadvantage in wetting down fine sizes of bituminous coal? C. R

Wetting down makes cleaner handling, permits of better spreading and is accompanied by much less annoyance from back draft, and less combustible material is carried over by the draft into the combustion chamber. The tendency of fine coal to pack in the furnace is overcome by wetting the coal; as the steam thus generated opens the mass, the coal is burned more uniformly and more completely and with fewer cracks and large holes in the fire. The principal disadvantage is that the water used for wetting down the fuel requires heat for its evaporation into steam which is discharged to the chimney as superheated steam at atmospheric pressure; but with good spreading of the moistened fine fuel this loss will generally be more than offset by the requirement of less excess air to burn the coal on account of the more uniform distribution of draft passages through the fuel bed.

Density and Volume of Steam—What is the meaning of the density and volume of steam? A. H.

The density of a body is its mass per unit of volume, and the customary unit is pounds per cubic foot. The density of steam, therefore, is its weight in pounds per cubic foot. The density of steam or weight per cubic foot varies with the pressure. Thus, as shown by tables of properties of steam, the density of dry saturated steam at 0 gage or atmospheric pressure (taken at 14.7 lb. per sq.in. absolute) is 0.3732 lb., at 50 lb. gage (or about 65 lb. absolute) it is 0.1503 lb., and at 100 lb. gage (or about 115 lb. absolute) it is 0.2577 lb. per cu.ft. The specific volume is the number of cubic feet per pound. Therefore the specific volume is the reciprocal of the density. Thus if the weight of 1 cu.ft. of steam at 100 lb. gage is 0.2577 lb., then the volume, or space occupied by a pound, is $\frac{1}{0.2577} = 3.88$ cu.ft. per lb. Steam tables generally give both specific volume and density for different pressures.

Induction-Motor Winding Connections—Why is the secondary winding of a wound-rotor induction motor generally connected in star instead of delta? R. A.

What is true of the rotor winding may also be applied to the stator winding. Where possible both windings are connected in star. The reason for this is, that with a given weight of copper in the winding the star-connected winding is 173 per cent. as effective as the delta-connected winding. Expressing this another way, the star-connected machine requires only 58 per cent. of the copper of a delta-connected machine of the same type and capacity. The voltage generated in the secondary winding when star connected will be 1.73 times as great as that generated in the same winding when delta-connected, and the current will be in inverse proportion to the voltage. This lower current for the star connection will generally simplify the design of the controller. There are also other factors in favor of the star-connected winding such as, the coil requires a smaller number of turns, less time to place the winding on the core and the winding can be more easily insulated.

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Combustion of Coal and Design of Furnaces

A review of Bureau of Mines Bulletin No. 135, which deals with the combustion of coal and the influence of furnace design upon combustion. The bulletin is one of a number issued by the Bureau and dealing with the economical utilization of the nation's fuel resources. The tests with which the bulletin deals were made in a Murphy stoker furnace of special design, at the end of which was a Heine boiler. The fuels used were Pocahontas, Pittsburgh and Illinois coal. Exceedingly interesting data relative to the combustion space or volume required for the different coals and different rates of combustion are given. Different furnaces and different fuels require different percentages of excess air to give the best results; some furnaces and some fuels may give the best results with high percentages of CO_2, whereas others may have to operate with a comparative low CO_2 content.

ABOUT a year ago, the Bureau of Mines issued a technical paper of considerable importance under the title, "Combustion in the Fuel Bed of Hand-Fired Furnaces." This was practically a virgin field, inasmuch as little or no experiments or investigations of the behavior of gases in the fuel bed of a furnace had been made. The astonishing fact revealed was that the CO_2 reached its maximum at about 4 in. above the grate in a 6-in. fuel bed, the fuel bed being presumably free of ash. All the free oxygen in the air admitted under the grate was shown to be consumed in the 6-in. fuel bed 4 in. above the grate, or 2 in. below the surface of the fuel bed. This paper was fully reviewed in *Power* for May 8, 1917, p. 640. The Bureau in carrying out its investigations made its next step the investigation of the behavior of the gases in the combustion space of the boiler furnace, and the results of these investigations are presented in Bulletin 135 by Henry Kreisinger, C. E. Augustine and S. K. Ovitz, who are the authors also of the Technical Paper No. 137.

The present bulletin, No. 135, is, we believe, the most valuable publication the Bureau has yet issued on the subject of combustion. Certainly no publication contains a similar wealth of data for the man who designs furnaces or who must operate them economically. The tests were made with Pocahontas, Pittsburgh and Illinois coals burned in a Murphy stoker (side-feed) furnace of special design. The furnace was exceedingly long, being 43 ft. 4 in. in length from the boiler to the front wall of the furnace. The firebox itself is 5 ft. wide by 5 ft. deep. The furnace is essentially a brick tunnel 3 x 3 ft. in cross-section, the stoker having 25 sq.ft. of projected grate area. The arch over the grate surface contains an air space through which air is delivered to the tuyeres supplying air over the fuel bed. Observation holes were placed every 5 ft. apart along the length of the furnace. Although the data were obtained from experiments with a Murphy furnace and are therefore particularly applicable to furnaces of that type, it is believed that they may be of value as a guide in the proportioning of other furnaces. When applying the data to other furnaces, the designer should give full consideration to the method of introducing secondary air and the facility for mixing it with the combustible rising from the fuel bed. For best results the secondary air should be introduced as near to the fuel bed as practicable, and the air should be supplied in a large number of streams at high velocity.

The gases rising from the fuel bed of a Murphy stoker contain 10 to 28 per cent. by volume of combustible. If the gases flowed through the combustion space, they mixed with the air added over the fuel bed and burned. Because of this combustion, the percentage of combustible decreases along the path of the gases, the rate of decrease being rapid at first, but slowing down as the gases move farther from the fuel bed. Inasmuch as the gases rising from the fuel bed contain 10 to 28 per cent. of combustible and practically no free oxygen, additional air must be supplied over the fuel bed to insure complete combustion. That this additional air may flow into the furnace, the pressure of gases in the furnace must be below that of the outside air. The composition of the furnace gases at various distances from the fuel bed is shown in Fig. 2. The rate of combustion in this case was 35.6 lb. of coal per sq.ft. of grate; the coal was Pittsburgh screenings. The curves show that the gases leaving the fuel bed contain over 25 per cent. of combustible gases, about 1 per cent.

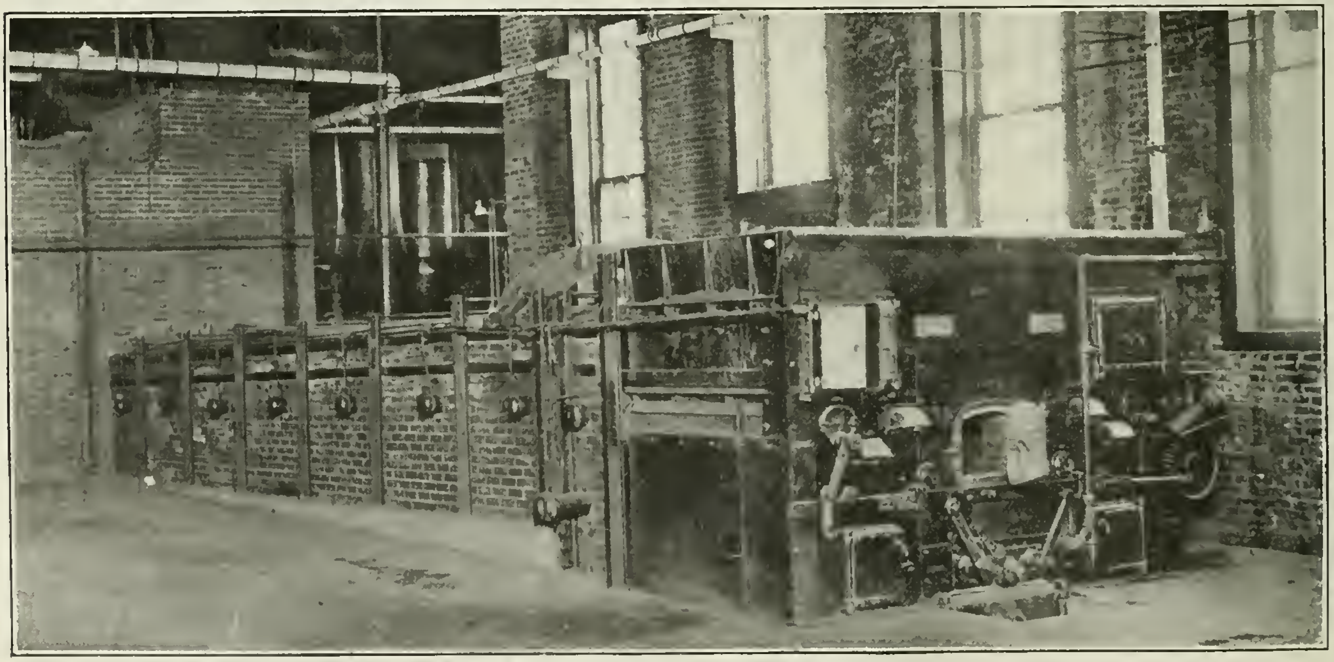

FIG. 1. EXPERIMENTAL FURNACE, SIDE-FEED STOKER; FURNACE 45 FT. BY 5 FT. SECTION

of O_2 and 7 per cent. of CO_2. Before these gases reached section *A* of the furnace, which is a point about 6 ft. from the inside front furnace wall or a point about 1 ft. beyond the firebox proper, enough air was added to make the total air supply exceed the amount theoretically required by 19 per cent. Most of this air was added through the tuyeres near the surface of the fuel bed and in a way that facilitated its mixing with the combustible gases rising from the fuel bed. In view of all that has been said about the value of high boiler settings and great furnace volume, it is interesting to note that in this figure little combustible gas is left after a distance of 13½ ft. from the grate is traveled through and by the gases. If we refer to commercial practice in furnace design, we observe that engineers have been increasing the height of boiler settings or increasing the furnace volume. Those who, five to six years ago, allowed but 8 ft. from the bottom front header of an ordinary B & W boiler to the floor line allowed 10 ft. in later design, and in still later design they have allowed as much as 12 ft. It would seem, from the experiments told of in this bulletin that inasmuch as the combustion rate greatly influences the furnace volume required, and inasmuch as high rates of combustion are required to carry peak loads, the 12 ft., which probably represents the maximum in modern practice, is still short of the most desirable height. Of course, volume alone is not sufficient in commercial boilers, and the authors mention this fact. There also should be provisions for mixing the combustible gases and the air for combustion.

In the most recent installations of the "W" type Stirling boilers by the Detroit Edison Co., the distance from the bottom of the middle drum to the dump plate is 33 ft. It is 28 ft. in the old Delray boilers. Vertically baffled boilers are now being set 12 ft. from floor to front headers.

The authors say that the length or volume of the combustion space required for practically complete combustion seems to depend chiefly upon the percentage of excess air, the rate of combustion and the kind of coal.

INFLUENCE OF EXCESS AIR

Comparison of different curves plotted by the authors show that for the same rate of combustion when the excess air is large, the proportion of combustible gases is less at any given cross-section (distance from the firebox) of the furnace and the combustion is practically complete in a smaller combustion space than when the excess air is small. Investigations show that as the size of combustion space increases, the minimum losses are obtained with a lower excess of air and a higher percentage of CO_2 in the furnace gases. The minimum losses in the furnace having a small combustion space are much larger than the minimum losses in the furnace equipped with a large combustion space. However, with a large combustion space the minimum losses extend over a much smaller range of excess air than they would with a smaller combustion space. This means that with a furnace having a large combustion space, more skill is required to keep its performance within the narrow range of minimum losses or maximum efficiency than to operate a small furnace at its best. With the furnace having a small combustion space a variation of 50 to 100 per cent. in the excess of air makes little difference in the performance of the furnace. However, the maximum efficiency of the furnace having the large combustion space is so much higher than that of the furnace with the small space that there is little doubt left as to which is preferable.

It is interesting to note that at the surface of the fuel bed the combustible gases represent 35 to 65 per cent. of the total heat value of the coal. This means that under ordinary operation of the side-feed furnace about one-half of the total heat in the coal is developed in the fuel bed, the other half being developed in the combustion space. Among other factors, it depends upon the size of the combustion space how much of the 50 per cent. of heat left in the combustible rising from the fuel bed is developed. There then follow in the bulletin a number of curves showing the relation between the completeness of combustion and the length and volume of the combustion space; also the effect of the excess of air and the rate of firing on the completeness of combustion at the various sections of the combustion space.

Figs. 3 and 4 (Figs. 29 and 30 of the bulletin) may be used for determining the size of the combustion space required for given conditions in the following manner: Suppose that it is desired to design a furnace that will burn Illinois coal at the rate of 40 lb. per sq.ft. of grate per hour with 50 per cent. excess of air, and with an incomplete combustion of only 2 per cent. of the heat in the coal as fired. For the solution of this problem the left half of Fig. 3 can be used. Refer to the group of curves designated by 2 per cent. (undeveloped heat) at the left margin. From the intersection point of the horizontal line of 40 lb. rate of combustion with the curve of 50 per cent. excess of air, a vertical line is followed to the bottom of the figure, where, in the second scale, the size of the combustion space is found to be 5.8 cu.ft. to every square foot of grate. The first scale indicates that the length of gas traveled for this condition should be about 18 ft. The first scale at the bottom indicates that, with the experimental furnace, about 145 cu.ft. of combustion space was needed to satisfy the given conditions, the space extending to within 1 ft. of section *B* of the furnace, which is at a distance approximately 10 ft. from the front wall of the furnace or firebox.

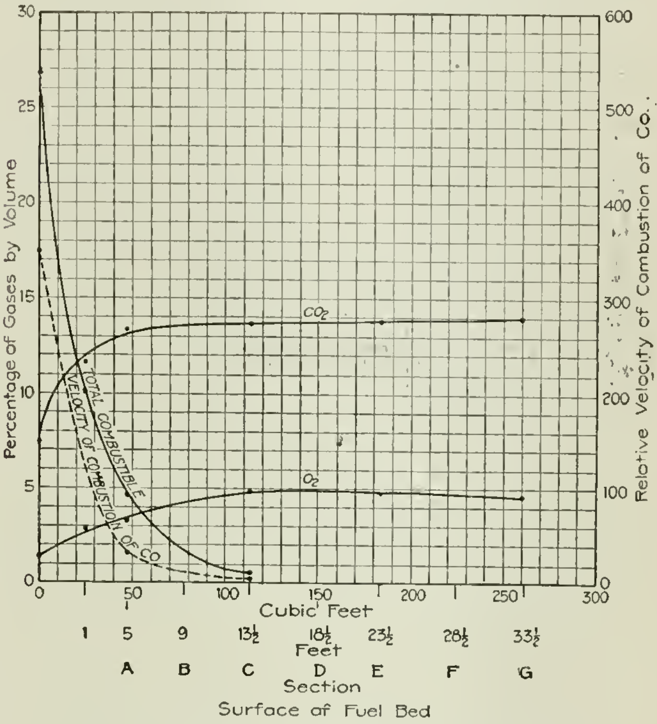

FIG. 2. PROGRESS OF COMPOSITION OF GASES AT VARIOUS DISTANCES FROM THE FUEL BED

If Pocahontas coal is to be burned under the same conditions, the required size of the combustion space is obtained from the group of curves designated by 2 per cent. undeveloped heat in the right half of the same figure. From the intersection point of the horizontal line a rate of combustion of 40 lb. with the curve of 50 per cent. of excess air in the vertical line is followed to the bottom of the figure, where the second scale indicates that about 3.2 cu.ft. of combustion space is needed for every square foot of grate area and that the length of the gas path should be about 10 feet.

When Pittsburgh run-of-mine coal is to be burned, it is found in the same manner from the left half of Fig. 4 that the best results can be obtained with a rate of volume to grate area of about 3.9 to 1 and an average length of gas travel of about 12 feet.

Thus, the three coals, Pocahontas, Pittsburgh and Illinois, require 3.2, 3.9 and 5.8 cu.ft. of space per square foot of grate, respectively, to burn 40 lb. of coal per square foot of grate per hour, 50 per cent. excess of air and incomplete combustion of 2 per cent. of the total heat in the coal as fired. According to the right half of Fig. 4, when burning Pittsburgh screenings, only about 3.1 cu.ft. of combustion space is required per square foot of grate to burn the coal with the same results. This is about the same combustion space required per square foot of grate to burn Pocahontas coal.

When considering the volume of combustion space, it is well to add that the length of the gas travel is probably an important factor. It seems that a long narrow combustion space is more efficient in burning the gases than a short wide one having the same cubical space. In the long narrow space, the gases travel with a higher velocity, which promotes mixing and therefore quickens the combustion. In the short wide space, the gases remain the same length of time, but travel slower. On account of this slower movement, the gases are less agitated and tend to travel in stratified streams. Therefore, there is less mixing and the combustion is slower. It is advisable that in using the data of Figs. 3 and 4 in designing a furnace, the path of the gases be made nearly as long as in the experimental furnace as practicable.

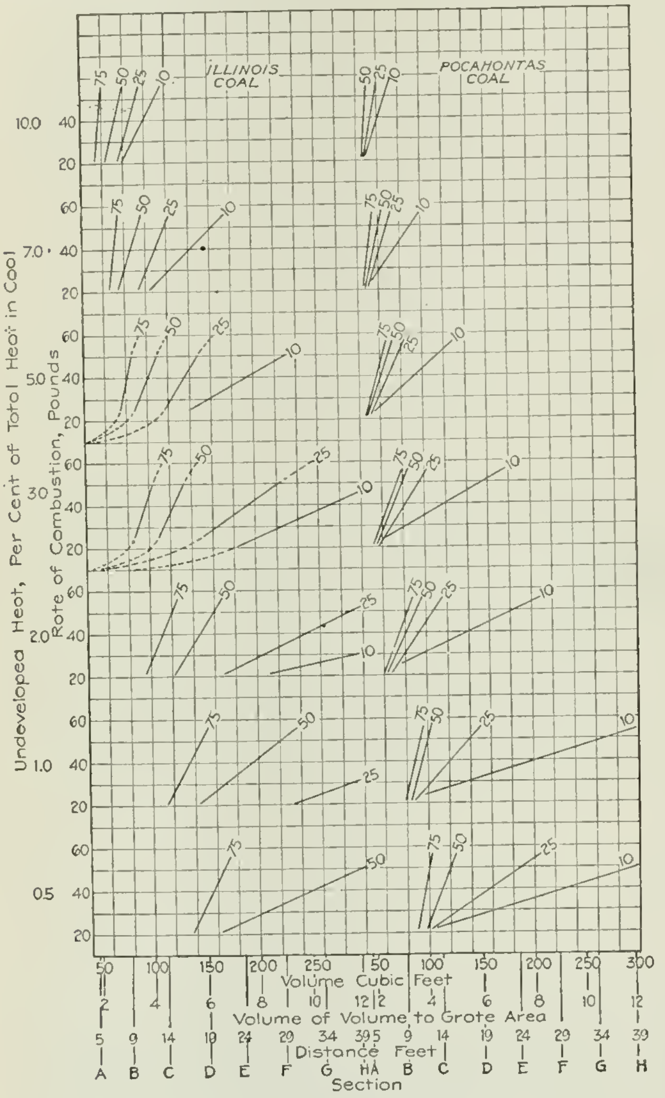

FIG. 3. COMBUSTION VOLUME REQUIRED FOR ILLINOIS AND POCAHONTAS COALS

Shows the relation between the required combustion volume, given completeness of combustion, rate of firing and excess air. Figure on each curve indicates percentage of excess air.

Table V of the bulletin (here Table I) is one which undoubtedly should be of practical value to the designer of furnaces or to the man responsible for furnace alterations. The table gives the size of the required combustion space for the three coals and several sets of conditions indicated by columns 1, 2 and 3 of the table. Examination of the values in columns 4, 5 and 6 shows that the size of the combustion space does not increase in direct proportion to the percentage of volatile matter in the coal. The increase in the combustion space from Pittsburgh to Illinois coal is much larger than the increase from Pocahontas to Pittsburgh coal. Roughly speaking, under the same conditions Pittsburgh coal requires about 20 per cent. larger combustion space than Pocahontas coal, while Illinois coal requires about 40 per cent. larger combustion space than Pittsburgh coal. That the size of the combustion space does not increase in direct proportion to the percentage of volatile matter in the coal is shown graphically in another curve of the bulletin designated as Fig. 31, which curve does not appear here. If the relation of the size of the combustion space to the percentage of volatile matter were a direct proportion, the relation would be represented by a straight line. The curves are far from straight lines and become more and more curved as conditions of less complete combustion are considered and the combustion space becomes smaller. However, in the opposite direction toward complete combustion the curves seem to approach a straight line.

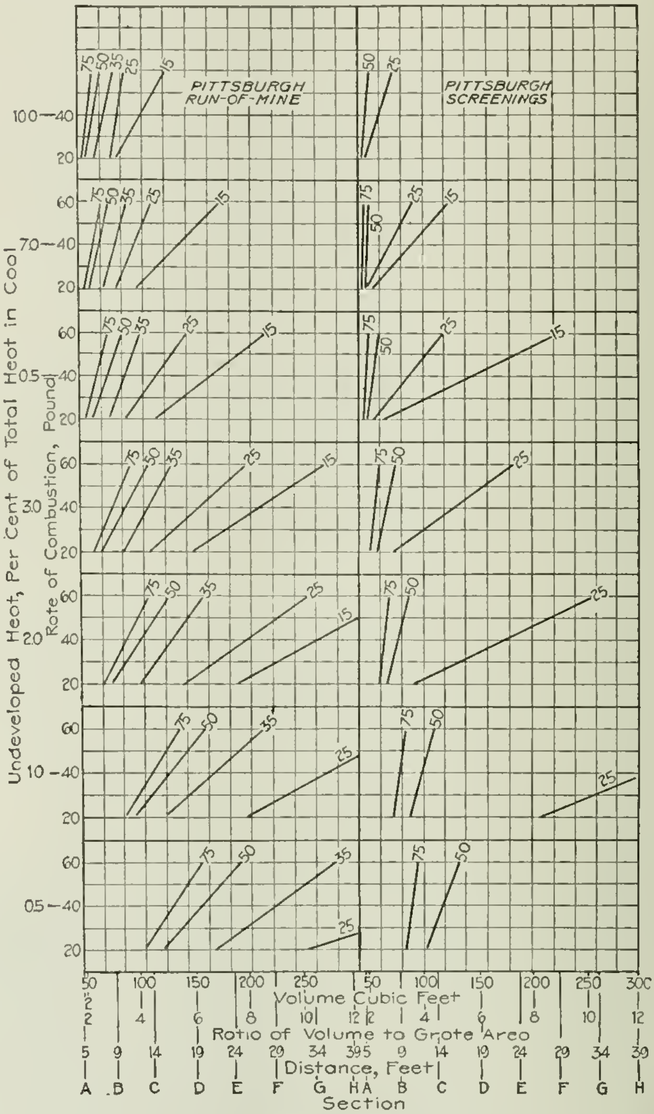

FIG. 4. COMBUSTION VOLUME REQUIRED FOR PITTSBURGH COALS

Figures on curves denote excess air

That the size of the required combustion space under ordinary degrees of completeness of combustion does not vary in direct proportion as the quantity of volatile matter even if the quality of the latter remains constant can be deduced from Table V by comparing the two rates of combustion of the same coal. Thus, when the rate of combustion is doubled, the quantity of the volatile matter distilled per unit of time is doubled. However, to burn this double quantity of volatile matter with the same excess of air to the same completeness, the combustion space is increased only about 20 per cent.

The following paragraph is quite significant in view of the experience that we have had in the burning of coal in a practical way. It explains why some settings fail in one place and succeed in another.

The quality of the volatile combustible, as far as the ease of burning is concerned, is perhaps best expressed by item 6 in Table I, showing the ratio of volatile carbon to available hydrogen. These values were obtained by dividing the volatile carbon by the available hydrogen and are probably fair indicators of the burning qualities of the coals. The amount of volatile carbon was computed by subtracting the amount of fixed carbon from that of the total carbon. The available hydrogen is equal to the hydrogen content on a moisture and ash-free basis minus one-eighth of the oxygen content. The ratio shows that the volatile matter of the Pittsburgh coal contains nearly twice as much carbon, and that of the Illinois coal three times as much carbon, as the Pocahontas coal. These ratios indicate the probability that in burning Pocahontas coal, the volatile combustible is distilled mostly as light gases which are easily burned in the diluted furnace atmosphere, whereas, in burning Illinois coal the volatile combustible leaves the fuel bed mostly as heavy hydrocarbons in the form of tars, which, in the diluted oxygen of the furnace atmosphere, are first decomposed into the lighter hydrocarbons and carbons, the latter being precipitated as soot. This mixture of soot, tar and gases burns slowly and requires a large combustion space for its complete combustion.

TABLE I. COMBUSTION SPACE REQUIRED FOR POCAHONTAS, PITTSBURGH AND ILLINOIS COALS

Completeness of Combustion, per Cent. of Undeveloped Heat	Rate of Combustion, Lb. per Sq. Ft. of Grate per Hr.	Excess of Air, per Cent	Cubic Feet of Combustion Space per Sq.Ft Grate		
			Pocahontas	Pittsburgh	Illinois
1	2	3	4	5	6.
5	50	50	2 7	2 9	4 3
3	50	50	3 2	3 7	5 3
2	50	50	3 6	4 4	6 3
1	50	50	4 0	5 6	8 9
0.5	50	50	4 8	6 8	11 9
5	25	50	2 0	2 2	3 5
3	25	50	2 3	2 7	4 35
2	25	50	2 7	3 1	5.1
1	25	50	3 4	4 0	6 2
0.5	25	50	4.0	5.0	7 1

In general, the higher the carbon content in the carbon-hydrogen compound the more time is required for their combustion. Therefore, it may be expected that as the ratio of volatile carbon to available hydrogen increases, the size of the combustion space required for a given degree of completeness also increases. In a rough way, when nearly complete combustion is desired, the size of combustion space varies directly as the product of the quantity and quality of the volatile matter as the two are given in items 1 and 6 of Table IV (here Table I). As the combustion becomes less complete, the curve showing the relation between this product and the size of the combustion space is farther from a straight line. Distillation at low temperatures favors the formation of light hydrocarbons of the paraffin series, which contain more hydrogen and less carbon than the hydrocarbon of the aromatic group, which are distilled at high temperature. The hydrocarbons of the paraffin series are more stable at high temperatures and, on account of their higher hydrogen content, are more likely to burn completely without depositing soot. It requires one molecule of oxygen to burn completely one atom of carbon, whereas one molecule of oxygen burns completely four atoms of hydrogen. Thus, of two compounds having the same number of atoms in a molecule, the one having more hydrogen requires less oxygen for its combustion, and therefore, in the same concentration of oxygen, will burn more readily. The authors here go into quite a detailed statement relative to the composition of the various hydrocarbons, and the discussion shows the advantage of distilling volatile matter at low temperatures, producing mostly paraffin or other hydrocarbons of this group. The furnace should be so designed that distillation takes place at low temperature. After the volatile matter is distilled, air should be added and the mixture thus passed through a hot chamber, especially with the smoky coal, for the reason that slow and uniform heating of the coal occurs when the coal is highest in volatile contents, or in other words, when it is admitted to the furnace distillation taking place in a low temperature and in the presence of oxygen. With most of the common types of mechanical stokers the distillation of volatile matter occurs in the presence of oxygen, whereas in hand-fired furnaces distillation is almost in entire absence of oxygen, all of the latter being consumed as it passes through the fuel bed. Even if there should be some tendency to decomposition with the mechanical stokers, the presence of large percentages of oxygen at the point of distillation makes it possible for the hydrocarbons to react with oxygen before the deposition of carbon can really take place. High temperatures, such as exist in boiler furnaces and in the absence of oxygen, promote the decomposition of all hydrocarbons, including methane, the lightest of the paraffin series, one of the products of decomposition being soot. When methane is burned with insufficient air supply, it burns with a yellow flame and deposits soot. It should, therefore, be burned with some excess of air and with provision for obtaining a good burning mixture, otherwise soot will be deposited.

The authors devote considerable space to a discussion of soot and its formation. The subject is interesting and important enough to warrant mention here. Tests show that the combustible matter rising from the fuel bed was roughly 12 per cent. in the form of tar and soot. The coal was Pittsburgh screening. Immediately at the surface of the fuel bed the quantity of tar is largest, but decreases rapidly as the gases pass through the combustion space. On the other hand, the soot increases during the first foot of gas travel. In general, an increase in the rate of combustion and in the excess of air is accompanied by a decrease in the quantity of soot, particularly in the quantity of tar. With all rates of combustion and all excess of air, there is a large decrease in the quantity of tar and a moderate increase in the quantity of soot, during the first foot of the length of gas travel.

This decrease in the quantity of tar and increase in the quantity of soot seems to indicate that the volatile matter leaves the fuel bed as heavy hydrocarbon mostly in the form of tar. These tars are decomposed by the high furnace temperature and in the absence of oxygen into soot and lighter, more gaseous hydrocarbons. The process of the decomposition of the hydrocarbons very likely consists of a number of consecutive reactions each step of which is accompanied by the deposition of soot and formation of lighter hydrocarbons. This process of decomposition is complicated by the presence of CO_2, which reacts with the soot and combustible gases and is itself reduced to CO. The decomposition and reduction proceed toward the simple gases CO and H_2.

TABLE II. CHEMICAL CHARACTERISTICS OF THREE COALS TESTED

	Pocahontas Coal	Pittsburgh Coal	Illinois Coal
1. Volatile matter in moisture and ash-free coal, per cent	18 05	34.77	46 52
2. Fixed carbon in moisture and ash-free coal, per cent	81 95	65.23	53.48
3. Carbon in moisture and ash-free coal, per cent	90 50	85 7	79.7
4. Volatile carbon in moisture and ash-free coal, per cent	8 55	20 47	26 22
5. Available hydrogen in moisture and ash-free coal, per cent.	3 96	4 70	3.96
6. Ratio of volatile carbon to available hydrogen, per cent	2.16	4.35	6.6
7. Oxygen in moisture and ash-free coal, per cent	3.32	5.59	10 93
8. Nitrogen in moisture and ash-free coal, per cent	1 19	1 73	1.70
9. Moisture accompanying 100 per cent. of moisture and ash-free coal, per cent	2.53	2 88	22.07
10. Volatile matter times ratio of volatile carbon to available hydrogen (product of items 1 and 6)	39 0	151 00	307 00
11. Ratio of oxygen to total carbon, in moisture and ash-free coal	0 0367	0.0652	0 137
12. Total moisture in furnace per lb. of coal reduced to moisture and ash-free basis, lb	0 409	0 501	0 70

The length of time in which the tars are decomposed into soot and gases is short. At the rate of combustion of 30 lb. per sq.ft. of grate per hour, the gases travel with a velocity of about 10 ft. per second. As most of the tar disappears during the first foot of the gas travel from the fuel bed, the time taken for the decomposition of the tar is about one-tenth of a second. This high rate of decomposition is undoubtedly due to the high temperature near the fuel bed, which in the test was probably not less than 1500 deg. C., or 2732 deg. F. This is a dazzling white heat. In the light of the preceding discussion it appears that soot, which is the main constituent of visible smoke, is formed at or very near the surface of the fuel bed and not at the place where the furnace gases strike the heating surface of the boiler. The heating surfaces merely cool the gases surrounding the soot, thereby preventing its combustion. The formation of soot at the surface of the fuel bed is caused by the high furnace temperature and absence of oxygen. It is possible that if oxygen was present in sufficient quantity at the time of distillation of volatile matter, the heavy hydrocarbons would burn directly to products of complete combustion, CO_2 and H_2O, without first decomposing and depositing soot. After the soot has once been formed, it is difficult to burn it in the atmosphere of the furnace. This fact has been observed by many investigators, and some of the early writers on combustion even considered soot as noncombustible. At present no support can be found for this extreme view. As a matter of fact all combustible substances burn slowly in an atmosphere of highly diluted oxygen, but in the case of soot this slowness is much more pronounced. The reason for the very slow combustion of soot in highly diluted oxygen probably lies in its complex molecular structure. The chances of the molecule of soot finding the 12 molecules of oxygen presumably required to burn it are small.

CRACKING OF TAR IN THE FURNACE

Tar exists in the furnace in the form of vapor, an ideal condition for cracking. The small globules present a large surface for absorption of heat from the gases and hot furnace walls and are quickly heated to a high temperature which favors the formation of carbon.

On account of the complex nature of tar, a great many reactions are involved in its decomposition. In general, the cracking is similar to that of hydrocarbon gases, but many more compounds are involved, and the result is a complicated equilibrium among a large number of hydrocarbons. Little experimental data are available on equilibrium and the velocity of these reactions; however, the high temperature in the furnace and the fact that the tar is in a state of subdivision favor rapid cracking and the formation of large amounts of carbon. This view is supported by the results shown in Fig. 44 of the bulletin, but not given here. The greatest amount of tar is found with a larger proportion of soot. The amount of tar and the gases decreases rapidly as the distance from the fuel beds increases; at an average distance of 5 ft., the tar has nearly disappeared. The velocity of combustion of hydrocarbon is faster than the velocity of decomposition; therefore, combustion will take precedence over decomposition for this reason. Air supplied over the fuel bed should be admitted as near to the surface of the bed as possible and mixed with the hydrocarbons so that they will be burned before they are decomposed by heat and form smoke, which is difficult to burn in the diluted oxygen of the furnace.

Pages 125 to 134 are devoted to an interesting explanation of the chemistry of combustion as carried on in a boiler furnace. These pages are omitted in this review.

What the authors have to say relative to the future method of using bituminous coal is interesting. Difficulty in burning bituminous coal in industrial furnaces is due almost entirely to the volatile matter because this leaves the fuel bed as gases and tars and must be burned in the combustion space of the furnace. Unless enough air is introduced immediately at the surface of the fuel bed and thoroughly mixed with the volatile combustible, the tars and more complex combustible gases are quickly decomposed or cracked into soot and simple gases. The soot thus formed is difficult to burn in a dilute furnace atmosphere and is likely to pass out of the furnace as black smoke, particularly if the furnace is hand-fired. The fixed carbon is easy to burn because it stays on the grate. It burns partly to CO_2, partly to CO, which in turn can be burned to CO_2 with additional air introduced above the fuel bed. The authors here point out that the various measures tried by individuals and cities to prevent smoke have, on the whole, done but little to solve the problem. In view of what is known of the chemistry of fuels and the possible advancement of such knowledge in the near future, it is questionable whether the method used in attacking the smoke problem was the best as regards fuel economy, the authors say. The persistence of smokiness in burning bituminous coal shows that there is room for improvement in methods of burning. The volatile matter of bituminous coal would have greater economic value if converted into gas or liquid fuel than if burned under steam boilers. Under present market conditions heat in the form of coal gas brings eight to sixteen times the price of an equivalent amount of heat in the form of coal. Gas is an extremely convenient fuel and can be used to advantage for many purposes, such as cooking, lighting and heating buildings, municipal lighting and in some industrial plants for obtaining a uniformly high temperature and clean products of combustion. The residue from the coking coals should find a ready market for househeating and for steaming purposes.

By the application of proper processes, it seems possible to reduce a large part of the volatile matter to liquid, of which an appreciable percentage could be obtained in the form of light oils suitable for motor fuels. Benzol has been obtained at byproduct plants for many years without any special effort to produce it. There is no doubt that with well-developed methods the yield of benzol and similar oils could be greatly increased. The value of heat in the form of motor fuel is twenty to thirty times as great as that of heat in the form of coal.

As the supply of bituminous coal is enormous, the uses of the oil are practically unlimited and the margin of profit in the conversion is large, it would seem that the development of highly productive methods would be rapid. By itself, the coke residue from such plants would have considerable commercial value, and if its price were made equivalent to that of coal, it would doubtless find a wide margin for house-heating and steaming purposes. The higher the percentage of volatile combustible the higher will be the commercial value of the coal. The time may come when our views of the relative values of different coals will change, and we shall consider anthracite as of minor importance as compared with the high-volatile bituminous coals.

The authors say that reports from Europe indicate that after the war the world will be informed of some extraordinary developments in the utilization of bituminous coal in certain countries, and that these developments will be of striking importance to the manufacturers of the United States.

The bulletin is one that every engineer concerned with furnaces, stokers and combustion should include in his library. It may be had free by addressing the Director, Bureau of Mines, Washington, D. C.

Engine Wreck from Unusual Cause

An item in the Swiss engineering journal, *Schweizerische Bauzeitung*, tells of the breakage of a cylinder head due to an unusual cause, bad lubricating oil.

The rear cylinder cover of a 500-hp. uniflow steam engine was forced out during operation but not by waterhammer, the usual cause. The cause of the break was found to be in the bad quality of the cylinder oil (tar oil). The deposit from this very thick oil, which also contained various mechanical impurities, accumulated on the piston and cylinder-head surfaces in a continually thickening crust which finally filled the entire clearance space at the back end of the cylinder and in time began to strike, compressing the substance more and more solidly and finally forcing the cylinder head out.

A saving of 25 per cent. in ammonia consumption by ice and refrigeration plants will mean several million pounds annually for munitions. A pound of ammonia will make 20 hand grenades. Ice cream and refrigeration concerns are asked to do everything in their power to stop waste and leakage of ammonia, and report on the first of each month what is being done to conserve it.

Steam-Electric Power-Plant Design*

By A. S. Loizeaux

IN THIS lecture the speaker generalizes on principles that may be used as a guide in power-plant design. It is most important for an engineer to consider and understand principles rather than individual facts, because every engineer's work presents problems of its own, which can be best solved only by applying general principles to decide the best design for the case.

It is necessary to pass the circulating water through screens located in the intake tunnel, to eliminate foreign materials. Friction through the screens will be a considerable item. The drop in head should be modest, perhaps not more than one or two feet, in order to reduce the lift required by the circulating pump. Stationary screens may be satisfactory where the water is exceptionally good, but where any considerable amount of foreign matter exists, revolving screens are required. Stationary screens were used at Westport, but they became clogged at frequent intervals. In some cases clogging resulted in a three-foot drop of head through the screen. This would take place in a few hours, the resultant pressure damaging the screens by bending. On raising the screens they would be found stopped with foreign matter and, in some cases, several wheelbarrow loads of fish and crabs. Revolving screens have eliminated these difficulties and give entire satisfaction. They are not operated continuously, but only at such intervals as the conditions require. The washing of these screens is automatically done by means of a pipe with high-pressure water impinging on the screen after it turns over the top guide.

Bunker Capacity Needed

The coal bunker should have a storage capacity for at least 48 hours' operation or more to provide for interruption of the coal supply. Automatic coal scales are now generally used to feed all stokers. Boiler-house records can then readily check the coal used by the plant, the duty of each boiler, and an efficiency test can be made on any boiler when desired.

The water-tube boiler practically holds the entire field in large power-plant work. Both straight-tube and curved-tube boilers are used.

Boiler horsepower has been by common agreement taken to be 10 sq.ft. of heating surface, this being approximately the heating surface required in old designs to produce one boiler horsepower of 34.5 lb. of water evaporated from and at 212 deg. F.

It has been found, however, that boiler capacity has been limited only by furnace capacity under the boiler and that with modern types of stokers the boiler capacity can be increased to double or even three times its normal rating. For the sake of uniformity, the normal boiler horsepower remains as before.

Economical boiler-house design today must provide for stokers, as may be readily seen by considering the investment required for a definite output. A hand-fired boiler will develop rated boiler capacity continuously, and under the best conditions may reach 150 per cent. A good stoker will deliver continuously twice rated boiler capacity and over peaks three times rated capacity, thus producing with the same boiler twice the output of the hand-fired boiler. It is evident that this is equivalent to cutting boiler-house investment nearly in half by the use of stokers.

The boiler setting required for underfed stokers must be higher than for hand-fired boilers, a space of ten feet from the stoker surface to the tubes being required for thorough combustion.

Draft through the fuel bed is provided by blowers in connection with stokers as before mentioned. It is not feasible to provide sufficient draft by this means, however, to carry the gases through the boilers, because a positive pressure in the furnace as compared with the atmosphere would produce a movement of the heated gases through the boiler setting to the outside and would soon destroy even the best firebrick. A slight negative pressure should be maintained in the combustion chamber, and this negative pressure or suction will therefore be increased throughout the several passes of the boiler and through the breechings to the stack. To provide this draft or negative pressure a chimney must be provided.

The draft available with given stack temperature is roughly proportional to the height of the chimney except that friction cuts down this proportion. The capacity in cubic feet per minute is roughly proportional to the cross-section of the chimney. Steel chimneys are sometimes used, but their upkeep is greater than for brick chimneys. A steel chimney should be lined all the way to the top to prevent corrosion on the inside, and it requires frequent painting on the outside. Masonry chimneys are made of perforated radial tile to conserve heat and material, and they are designed to be stable at various sections throughout their height. Their upkeep is negligible.

Mechanical Exhausters Unsatisfactory

Mechanical exhausters have been tried in lieu of chimneys, but have been unsatisfactory owing to the lack of reliability of fans working in high temperature. In designing breechings three points should be kept in mind: (1) Connections to stack should be as short as possible; (2) as few as possible changes in direction and use bends where this is unavoidable; (3) practically uniform speed of gas, requiring cross-section proportional to the gas carried.

A three-pass boiler has a distinct advantage in draft connections as compared with four-pass boilers because of lower friction and larger passes available.

Superheat of 100 to 200 deg. F. is used to improve the economy of generation. This also avoids water in the steam delivered to the turbine. The use of superheated steam requires the use of cast steel for all valve bodies and fittings, as cast iron under the greater heat will expand or grow until sometimes rupture occurs.

Pipes for high-pressure steam are made of wrought steel of about the same grade as boiler steel. The size of piping is determined by the speed of steam through piping to supply normally a maximum load. A few years ago engineers were using velocities of 10,000 ft. per min. and higher for normal load. It was found that these velocities produced a greater drop in pressure than was expected, the loss occurring possibly to a large extent in bends and fittings. Our present practice is to allow 8000 ft. per min. for normal load. When overloads are carried higher velocities may be produced, but as these periods are of short duration, they will not be serious.

Heaters Should Be Well Above Pumps

The use of a feed-water heater with water carrying solid matter in solution often acts as a purifier in causing this solid matter to separate out and be deposited, in the heater, as its temperature is raised. Heaters should be located well above boiler-feed pumps to provide positive heads. This requirement is due to the fact that hot water cannot be lifted by suction without breaking the water column due to liberation of steam. The temperature of water vapor at different negative pressures as compared with atmospheric pressure determines the critical point for any condition of suction with hot water.

The day when an engineer designs his own engine is passed. Today manufacturers are asked for bids and specifications on units of specified size. Alternative designs are often available, some being more efficient and costly than others. The choice of proper equipment then is determined by the cost of output when fixed cost as well as operating cost is included. In general the choice between high-efficiency, high-cost apparatus and low-cost, low-efficiency equipment is determined by the load factor, or hours of service per year. The higher the load factor on apparatus or plant the more will the effect of higher efficiency make itself felt. A plant that is held simply as stand-by in case of emergency and may operate only a few hours per year is evidently a case where lower cost would justify the use of low-efficiency apparatus.

---

*Abstract from a lecture delivered at the Johns Hopkins University, Baltimore, Md., Mar. 13, 1918, as one of the J. E. Aldred Lectures on Engineering Practice.

It is important that apparatus should be uniform in any plant to reduce the necessary stock of repair parts and make it simpler for the operating forces. There is a temptation in adding to a power plant to use apparatus, such as boilers, stokers and pumps, and different things, because of some slight advantage in design or cost. Some plants might almost be termed museums, due to the variety of apparatus. The designer should use the utmost care in first choosing type and make of equipment and then adhere to the standard set throughout the plant unless some great advantage unquestionably makes it wise to change. One advantage of standardizing is the greatly reduced engineering cost of adding to a plant by using additional duplicate units.

One of the fundamental lessons of practical power-house experience is the imperative need of spare equipment. One boiler in every five or six should be spare to provide for cleaning and repair and also for repairing the stokers. A spare turbo-generating unit is required in a power house whether the load calls for one or more units. The practical capacity of a plant is therefore its continuous capacity with one unit out of service. Thus a plant designed to carry 100,000 kw. should have the following number of units:

Each Unit	Number of Units	Total Rating, Kw.	Safe Capacity One Unit Out of Service, Kw.
10,000 kw	11	110,000	100,000
15,000 kw	8	120,000	105,000
20,000 kw.	6	120,000	100,000
25,000 kw	5	125,000	100,000

It will be seen that the larger the individual unit the greater capacity must be provided for spare, unless the number of units becomes large, and then more than one would be required for spare. The same principle of spare equipment is applied to the use of auxiliaries, the common design being to provide for two circulating pumps with each generating unit, also two air pumps and two condensate pumps. These auxiliaries are frequently supplied with both steam and electric drive for the double purpose of insuring reliability and also of controlling at will the amount of exhaust steam available for feed-water heating.

Those Damaged German Ships

When the history of this audacious war is fully written, there should be no more interesting chapter than that which deals with the interned German ships and their reappearance in a few months as auxiliary transports of the United States Navy. And this notwithstanding the damage inflicted upon them by Prussian orders was such as was calculated to keep them out of service for two years or what the Germans had figured as the period within which the war would terminate.

Thirty-seven German ships of 700,000 aggregate tons had their 74 engine cylinders so broken that repairs within any reasonable time seemed out of the question. The biggest ships appeared to call for new castings entirely beyond the capacity of any foundry works in the United States.

When the Shipping Board got down to close estimates, it figured the repair bill at $2,600,000 and time required 18 to 24 months. But American enterprise, combined with American invention, concentrated capital and industrial organization in large units accomplished the job in six to eight months at an expense of only $273,000. Every one of these ships has been for many weeks most effectively in Uncle Sam's service except possibly the "Armenia," lost off the Irish coast.

The Navy Department, says the Boston *News Bureau*, has figured that the saving in time at the going rate of tonnage had a value of not less than $240,000,000. One of the first ships tackled had four cylinders broken and it was estimated that 18 months would be required for repairs. In two months the engines were turning over, and in less than three months the ship was finished and ready for sea.

Indeed, the striking feature of the whole situation is the fact that the repairs on all the ships were made within the time required to overhaul the ships, clean their bottoms and otherwise make them ready for sea. The Germans had all their labor for their pains. What is also well-nigh incredible, the ships are stronger than before and the largest of them are more economically operated and are actually working better in the American than in the German hands.

Take the "Vaterland" for example. She is the biggest and most beautiful thing afloat. Stood up on Broadway, she would tower 200 feet above the Woolworth Building. She has 18 decks, 18 elevators, 5 kitchens, 530 clocks all timed from the main bridge, hot and cold water in every room, and many miles of piping, wiring and electric controls. This vessel was damaged as directed by the government to insure her being out of commission for at least two years. There were no foundries on this side of the ocean that could give the "Vaterland" new cylinder castings of 70 tons each, and no drydock that could receive her on this side of the ocean except at the Panama Canal.

It was found that the United States Steel Corporation had developed just the right wire soldering with the proper mixture of manganese and that the railroad repair shops around New York had developed the electric welding process of the General Electric Co. to a higher efficiency than anywhere else in the world. The railroad shops and the General Electric Co. were able to furnish the apparatus and the crews to repair the machinery of the "Vaterland" within the time required for general overhauling and cleaning of the ship's bottom by a half-dozen submarine divers who, among other things, took 280 bushels of oysters off the "Vaterland's" bottom.

The "Vaterland" was equipped with both Curtis and Parsons turbine engines, but the Germans have never been able to work them to full efficiency. Indeed, on the last trip to this country under German engineers, the "Vaterland" was able to use only part of her machinery. The American engineers adjusted everything, improved the machinery and the draft to her 46 boilers, improved the piping and valves and sent the giant forth in a few months at above a 21-knot speed and using 200 tons of coal a day less than before.

The Germans had figured that the "Vaterland" could never be repaired in the United States and if repaired was such a complicated piece of mechanism that it could never be operated by Americans or any new official staff. The officers of the big German ships have to be in training at least a year with their ships during construction. Now on the "Vaterland" in place of five German captains of the unlimited license class, there is but one American captain; and instead of a chief engineer and five assistant engineers, there is just one American chief engineer, and he is only 32 years of age.

The General Electric Co., the New York Central and the Erie Railroads all coöperated with electric workers and electric welding devices and what it was estimated would require five months on this ship was done in ten days. Thirteen breaks or cracks in the "Vaterland's" cylinders were mechanically patched by the electric welding system and made stronger than before, yet without a single rivet having to be put through the 3½ inches of metal.

It is said that Indian coal is the cheapest in the world. The coal now being worked is comparatively near the surface and labor is cheap. One of the difficulties in mining seems to be that a sufficient supply of labor is not always available when wanted, as the majority of the workmen follow the vocation of agriculture as well as mining and return to their homes during the periods of sowing and reaping. During the last 10 years the use of machinery has been rapidly extending, especially at the larger collieries. About 145,000 persons are employed in coal mining.—*Gas and Oil Power.*

The War-Savings Stamps project is, in reality, a two-billion dollar loan launched among the masses of the people and is intended for the benefit of those who cannot afford to buy the larger bond issues. It is a most democratic plan in that it reaches the entire population from coast to coast, men, women and children, rich and poor alike, and there certainly is not a person in this prosperous land so humbly placed that he or she cannot buy a 25c. Thrift Stamp as a tribute of loyalty toward Uncle Sam.

A. I. E. E. Discusses Single-Phase Induction Motors

The American Institute of Electrical Engineers held its 339th meeting in the Chamber of Commerce Building, Pittsburgh, Penn., Tuesday evening, Apr. 9, and in the Engineering Societies Building, New York City, Friday evening, Apr. 12, 1918. At New York a buffet dinner was served prior to the meeting, under the auspices of the New York Membership Acquaintance Committee.

The New York meeting was called to order at 8:15 by Vice President B. A. Behrend. Two papers were presented: "No Load Conditions of Single-Phase Induction Motors and Phase Converters," by R. E. Hellmund; and "A Physical Conception of the Operation of the Single-Phase Induction Motor," by B. G. Lamme. Mr. Lamme presented his paper in abstract and illustrated his remarks by diagrams on the blackboard. The paper covers a method of studying the action of the single-phase induction motor, which the author has found to be very convenient from the educational standpoint. It is based on the assumption of two equal and opposite rotating primary magnetomotive forces combined with a synchronously rotating secondary magnetomotive force, such as would be produced by direct-current excitation. A comparison is made between a two-motor unit consisting of two similar polyphase motors coupled together and connected for opposite rotation and the straight single-phase induction motor.

In the absence of the author Mr. Hellmund's paper was presented in abstract by A. M. Dudley, who explained its important details by the use of a number of lantern slides. In this paper methods are shown and formulas derived for the determination of the fields, the stator and rotor magnetizing currents, and tertiary voltages for phase converters and single-phase induction motors. The paper is of considerable length, occupying some 85 pages of the proceedings, and involves considerable mathematical analysis. However, it is arranged so that it can be read to good advantage without going through the major portion of the mathematics. The importance of the subject was demonstrated by the large number of prominent engineers who took part in the discussion. These were B. A. Behrend, Dr. Michael I. Pupin, E. F. W. Alexanderson, L. W. Chubb, Alexander M. Gray, C. A. M. Weber, Prof. C. F. Scott and Selby D. Harr.

One of the most prominent features brought out at the meeting was the lack of some simple method of presenting the action of the single-phase induction motor. The discussion of the paper was closed by B. G. Lamme.

Test of World's Largest Turbine a Success

Electrification of the Coast section of the Chicago, Milwaukee & St. Paul Ry. took a long step forward recently with the turning over for the first time of its big turbine generator, the largest in the world, at the White River, or Lake Tapps, generating station of the Puget Sound Traction, Light and Power Co., which has the contract for furnishing the power.

The turbine into which water was turned recently is one of 25,000-hp. capacity, and it constitutes the third unit in the White River plant. This plant is on the east side of Stuck River valley, five miles from Auburn, Wash., between Seattle and Tacoma, and is the largest and most important of the hydro-electric plants of the Puget Sound Traction, Light and Power Co. and one of the most remarkable in the world. It is built at the base of a high plateau between the Stuck and White Rivers, on which Lake Tapps is situated. White River was diverted above Buckley and emptied into the series of lakes of which Lake Tapps is the largest, and which form the natural storage reservoir. The water is taken from this reservoir through penstocks of inch steel 8 ft. in diameter at the intake and 6½ ft. at the power house. The penstocks are 2500 ft. long, and the water is fed to the turbines at a head of 465 feet. There are three units, each of one turbine, directly connected by shaft to the generator it drives. The first two turbines are of 20,000 hp. each. The new turbine is of 25,000 hp. and is the largest in the world. The total capacity of the plant with the added unit is 65,000 hp. This gives the traction company a combined capacity of all its plants supplying Seattle of 110,000 horsepower.

The Milwaukee road will require a little more than 50 per cent. of the additional power. The current will be delivered to the railroad at a voltage of 100,000, alternating current, and transformed into direct current at a voltage of 3000 for use on the motors of the Milwaukee electric locomotives. The traction company's contract with the railroad calls for the delivery of 10,000 kw. of 100,000 volts, alternating current. The railroad has yet to install substations and overhead trolley wires on the division between Othello and Tacoma. The trolley poles are now being placed in position, though operation electrically will be delayed for some time owing to a shortage in some classes of equipment. When this section of the Milwaukee electrification is completed, the road will be operated by electricity between Tacoma and eastern Montana.

War Convention of the Machinery, Tool and Supply Industry

The enormous problem of manufacturing and supplying machinery and tools sufficient for the carrying out of the Government program for the production of ships, shells, guns and aircraft will be the subject considered at the great "War Convention" of the machinery, tool and supply industry of the country to be held in Cleveland the week of May 13.

One thousand men who are bearing the brunt of the unprecedented demand for machinery will gather from all parts of the country to lay out a plan, with the aid of Government officials, to keep the great munition program going at top speed. The big war convention will be a joint meeting of four great national associations—the American Supply and Machinery Manufacturers' Association, the National Supply and Machinery Dealers' Association, the Southern Supply and Machinery Dealers' Association and the National Pipe and Supplies Association—which will meet together in order to coördinate their efforts toward one goal—"more ships, more shells."

"No industry has a greater responsibility at this moment than the machinery men," said H. W. Strong, president of the National Supply and Machinery Dealers' Association. "We must have men, but behind the men must be ships and munitions, and behind the ships and munitions, machinery —more machinery—still more machinery. We are in this fight to a finish. The Germans have convinced us that the only way out of the war is straight through, and the American machinery industry is ready to carry on to a knockout."

The part played by drills in the game of war is shown by the computation that 70 drilled holes are required in every 3-inch shrapnel shell, in every rifle 90, machine gun 350, torpedo 3466, war plane 4089, war truck 5946, war ambulance 1500, 3-inch field gun 1280, gun caisson 594, and anti-aircraft gun 1200.

"'Carry on' will be the watchword of the convention," said R. F. Valentine, president of the Maufacturers' Association.

New Power Development in Pennsylvania

Public-utility companies at Philadelphia, Penn., and vicinity are conferring with Government representatives for the development of the electric generating stations in the Lehigh Valley section of the state, supplemented by the construction of new transmission lines to connect with existing high-tension systems in Pennsylvania, New Jersey, New York and Delaware.

The proposed project, devised as a war measure and arranged with an idea of fuel conservation, will place the resources and ability of the different companies at the disposal of the Government. The Philadelphia Electric Co., Philadelphia, and the Electric Bond and Share Co., New York, the latter operating electric plants at Harwood Mines, Penn., and neighboring sections in this mining district for light and power service, are the two principal utility companies interested.

It is proposed to build extensions to a number of the existing generating stations to provide an increased output of at least 100,000 hp. Following this two or three new plants will be constructed, with total generating capacity of about 100,000 kw. The different stations will be tied in with a network of transmission lines, and a new high-tension system will be constructed to Philadelphia. Here it is planned to connect with the present lines of the Philadelphia Electric Co. and those of the Public Service Electric Co., operating in New Jersey, as well as with the system of the American Railways Co., which operates lighting and power properties in Pennsylvania, South Jersey and Delaware. The plan also includes a proposition to connect the new system with the lines of the Public Service Electric Co. at Newark and vicinity, and with New York City power lines.

Estimates of cost are now being made and different phases of the work investigated. While it is possible that the cost of the enterprise will be financed by the Government, this has not as yet been decided. The entire plan is designed to be of mutual benefit and not to the individual interest of any of the particular companies. William Potter, Pennsylvania State Fuel Administrator, and Charles E. Stuart, public-utility engineer for the Fuel Administration in the state, are representing the Government in the development plans.

Rights in Waters of Streams

A late decision of the North Dakota Supreme Court, handed down in the case of McDonough vs. Russell-Miller Milling Co., 165 Northwestern Reporter, 504, shows that an owner of land bordering a river has no unqualified right to object to use of waters of the stream by an upper landowner for manufacturing purposes.

Plaintiff complained that defendant's use of the stream by returning waters to it somewhat contaminated in their use rendered plaintiff's use less valuable, especially for the purposes of harvesting ice. But the court found that his rights, as governed by the following stated legal principles, had not been invaded:

The right of a riparian owner to have a natural stream continue to flow through or by his premises in its natural quantity and quality is subject to the right of each riparian owner to make reasonable use of the waters of the stream while remaining on his land. "Manifestly, running streams cannot be used for commercial, manufacturing or agricultural purposes and retain their pristine clearness and purity."

The question whether a reasonable or unreasonable use of the water is being made, having regard to the common rights of others, is to be determined by the circumstances of each particular case, due consideration being given to the character and size of the water course, its location and the uses to which it may be applied, as well as the general usage of the country in similar cases. . . Upon the question of reasonableness of the use by the upper proprietor, the character and extent of his business, as well as the use to which the lower proprietor is putting the water, may be taken into consideration.

Waste from Water Leakage

Water wasters cause unnecessary pumping that requires the use of 100,000 tons of coal annually in Chicago, in pumping and sterilizing 2½ times as much water as the consumers actually use, the waste and leakage amounting to more than the combined consumption of Milwaukee, Boston, Cleveland and St. Louis. The coal required for pumping this waste during one year amounts to more than enough to heat all its public schools during the winter. This useless pumping adds about half a million dollars a year to the operating expenses. Furthermore, three and a half million dollars is spent annually in an attempt to keep the plant adequate for the extravagantly excessive service, and even this amount is not sufficient. If the waste could be stopped, no further additions need be made for more than thirty years to come. The waste of water so reduces the pressure in the mains that for more than three-fourths of the area of the city it is less than half of that recommended by the National Board of Fire Underwriters, and in only one of the 35 wards does it equal the recommended pressure. With approximately 2,500,000 population, Chicago is pumping into its water mains 14 per cent. more water than New York receives by gravity (with no pumping costs) for the use of a population of 5,500,000. It supplies more water than any other water-works system in the world.

The startling facts here given are derived from a report entitled "The Water-Works System of the City of Chicago," that has just been published by the Chicago Bureau of Public Efficiency. The purpose of the report is to make public, and emphasize the enormous waste, and the undoubted increase in this waste of public funds which will occur unless radical methods are carried out for greatly reducing it.—*Municipal Journal.*

Thrift-Stamp Selling Machine

The War Savings Committee of Greater New York recently announced the placing of an order for 1500 Thrift Banks. These are really Thrift-Stamp selling machines which not only sell stamps for 25 cents but also register each sale.

The New York committee feels that this machine will greatly increase the sale of Thrift Stamps, and facilitate the handling of the stamps by merchants. The machines are meeting with great popularity everywhere. Frank Vanderlip, chairman of the National War Savings Committee, recently placed his stamp of approval upon them, expressing his hope that they would be adopted generally by the committees all over the country. Closely following Mr. Vanderlip's approval, the Treasury Department was so greatly impressed that it decided to put up the stamps in rolls of one hundred each at a little less than one cent per roll, in order to facilitate the feeding of the machine.

These machines are ideal for factories on payday or for any place where money changes hands or people congregate. Their use does not eliminate the personal solicitations, which are necessary if the War Savings Stamp campaign is to be a success. The first shipment of the New York Committee's order has already been started, and it is expected that within a few days everyone in New York will be able to purchase Thrift Stamps from this automatic salesman of Uncle Sam.

Full particulars regarding the machine will be furnished on application to the New York War Savings Committee, 51 Chambers St., New York City.

Conflicting Water Claims

In view of the fact that practically all Connecticut streams available for municipal water supply were long ago utilized for water power, either directly or through connecting waters, it must be supposed that a municipal charter, amended in 1901 and reaffirmed in 1909, empowering the municipality to condemn the waters of certain streams, contemplated appropriation of waters of streams that might already be used for water-power purposes at least when such water powers are not already employed in some other public use at the time of the proposed taking by the municipality. Respondent power company, although authorized to exercise the flowage rights of individuals and to use a brook to generate electricity, and although possessed of rights in the stream acquired for that purpose, is not entitled to defeat condemnation of waters of the stream by a municipality for water-supply purposes under statutory authority; the power company's property not being presently devoted, nor about to be devoted, to public use, within the general principle of law that property already appropriated to one public use cannot thereafter be condemned for an inconsistent public use. (Connecticut Supreme Court of Errors, East Hartford Fire District vs. Glastonbury Power Co., 102 Atlantic Reporter, 592.)

New Publications

FINDING AND STOPPING WASTE IN MODERN BOILER ROOMS. By Engineers of the Harrison Safety Boiler Works, Philadelphia, Penn. Cloth; 4¾ x 7 in.; 270 pages; 213 illustrations. Price $1.

The material contained in this book is both informative and timely. It is not original, but is a compilation of statements, tables and charts from various sources, the references being given in the majority of cases. Taken as a whole, it forms an authoritative treatment of the entire range of subjects relating to combustion and the economical management of steam-boiler plants, and is of value to owners, managers, engineers and firemen. The work is divided into five sections, the first of which deals with coal, its classification, analysis, heating value, purchase by specification, washing, storage and weathering, together with a brief notice of oil and gas as fuels. The second section takes up the chemistry of combustion, air required, grates, hand-firing methods, stokers and their operation, clinker, draft, stack proportions, draft gages, dampers, flue-gas analyses, excess air and smoke prevention. The third section treats of heat transmission, economizers, air heaters and superheaters, relation between heating surface and boiler capacity, boiler setting, firebrick, soot, scale, softening feed water and feed-water heating. The fourth section covers heat absorbed by boiler, heat losses, efficiencies, boiler capacity and boiler trials. The fifth section discusses various arrangements of auxiliaries with regard to their effect upon feed heating and also describes the Polakov functional system of boiler-room management.

Personals

Robert S. Blake, formerly representing the Condit Electric and Manufacturing Co., of Boston, in Pittsburgh, is now district manager of the Chicago office of the Duquesne Electric and Manufacturing Co., at 230 So. LaSalle St.

Engineering Affairs

The Bridgeport (Conn.) Section of the A. S. M. E. will meet on Apr. 24, and the New Haven Branch will meet on May 10.

The American Water-Works Association will hold its annual convention at the Planters Hotel, St. Louis, Mo., May 13, 1918.

George A. Orrok talked on Tuesday evening, Apr. 17, to the Student Branch of the American Society of Mechanical Engineers at Yale, on Internal Combustion Engines.

The Association of Iron and Steel Electrical Engineers announces the following meetings: The Cleveland Section on Apr. 27 at the Union League Rooms of the Statler Hotel. T. F. Bailey, president of The Electric Furnace Co., will present a paper on "Electric Soaking Pits, Annealing and Heat-Treating Furnaces and Furnaces for Melting Nonferrous Metals." The Philadelphia Section, at the Majestic Hotel, on May 4, at which H. A. Lewis and W. H. Burr will present a paper on "Electrically Operated Door Hoists for Openhearth Furnaces." In addition to this Major William A. Garret will address the meeting on "Some of My Observations in France." The Pittsburgh and Cleveland District Sections will hold a joint technical session at Youngstown, Ohio, on May 18, and make an inspection of McDonald and Ohio Works, Carnegie Steel Co.

Miscellaneous News

The Commercial and Industrial Museum of Montreal, Canada, has been established as an annex to the Faculty of Commerce, to furnish Canadian manufacturers and dealers information of interest to them in their business, and as a medium of advertising to Canadian and American customers. Manufacturers and exporters may get free space to exhibit their goods by communicating with the Museum at 399 Viger Ave., Montreal, Canada.

Concrete Ships—Edward N. Hurley, chairman of the United States Shipping Board, has recommended to the Secretary of the Treasury that the sum of $50,000,000 be authorized, of which some $15,000,000 shall be appropriated for the acquisition or establishment of plants suitable for concrete shipbuilding, or of materials essential thereto, or for the enlargement or extension of such plants as are now or may hereafter be acquired or established, and for the cost of constructing, purchasing, requisitioning or otherwise acquiring such concrete ships.

The House Naval Appropriation Bill for the year ending June 30, 1919, as reported from the Committee on Naval Affairs, contains numerous large appropriations for improvements and extensions to central power plants and distributing systems as follows: Navy Yard, Portsmouth, N. H., $150,000; Boston, Mass., $75,000; New York, $200,000; Philadelphia, Penn., $300,000; Norfolk, Va., $300,000; Naval Academy, $325,000; Naval Station, New Orleans, La., $280,000; Mare Island, Calif., $100,000; Puget Sound, Wash., $200,000; Marine Barracks, Peking, China (power plant), $25,000. Other items of general interest are as follows: For an investigation of fuel oil and gasoline adapted to naval requirements, $60,000; for aviation for naval purposes, $188,042,969; for expenses in connection with the civilian Naval Consulting Board, $100,000.

Two Applications for Permits to appropriate water which, combined, represent an outlay of $6,000,000 were recently filed in the office of State Engineer Lewis, Salem, Ore., by H. S. McGowan, of Pacific County, Washington. The application asks for a year in which to prepare plans and specifications of the proposed projects, and it is believed that the initial step that has been taken is in preparation for a possible legislation in Congress throwing open the waters to public development.

One application is to appropriate the waters of the Deschutes River to the extent of 45,000 cu.ft. a second. The proposed project is in Sherman and Wasco Counties, the river forming the boundaries between the two counties, and the purpose stated in the application is hydro-electric development and transmission for manufacturing purposes and general use. A dam which is being planned would be 118 ft. high, 800 ft. long at the top, 300 ft. long at the bottom, built of reinforced concrete with wasteway. The estimated cost of the project is $2,000,000.

The other application states the same purpose. The project proposed is in Jefferson County and would require 3500 cu.ft. per second. The estimated dimensions of the dam necessary are 236 ft. high, 420 ft. long at the top, 90 ft. long at the bottom, built of reinforced concrete of the overflow type. The estimated cost of the project is $4,000,000.

The Poget Sound Traction, Light and Power Co., Seattle, Wash., will have, when its present development is completed, hydro-electric plants supplying Seattle and Tacoma with power for industrial needs with a combined capacity of 107,997 hp. divided as follows: White River, 63,000; Electron, 18,667; and Snoqualmie Falls, 26,330, hp. The steam plant's capacity will aggregate 38,264 hp., 24,000 at the Georgetown plant, 6667 at Western Avenue, 4267 at Post Street, and 3330 in the Tacoma steam plants. The total capacity will then be 146,261 hp., which will be ample for some time. To the traction company's development must be added the hydro-electric and steam auxiliary plants of the Seattle municipal electric system, having a combined capacity of 24,000 hp. The White River or Lake Tapps development is the largest power project in the Northwest, and is still far from fully developed. It was made by diverting the flow of White River at a high point in its channel into three natural lake beds lying high on the plateau overlooking the lower White River valley. Twelve dams were constructed to create a reservoir and channel cut from the upper river to this reservoir. Before the work was done the company had to purchase 36 miles of riparian rights extending on both sides of the stream from the point of divergence 28 miles down to the point where the water again enters the river bed. By this means 2,500,000,000 cu. ft. of water is impounded. The station is located on the valley level of the lower river, and the water enters the penstocks from an outlet on top of the plateau.

Business Items

The Power Turbo-Blower Co., will move, on May 1, from 17 Battery Place to 347 Madison Ave., New York City.

The Whitlock Coil Pipe Co.'s Philadelphia office is now at 1009 Commercial Trust Building. William Wilcox, the district engineer, is in charge of the office.

NEW CONSTRUCTION

Proposed Work

N. H., Portsmouth—The Bureau of Supplies and Accounts, Wash., D. C., will soon receive bids for furnishing under Schedule No. 1766, at Navy Yard, here, 13,000 ft. plain rubber air hose for pneumatic tools and 5000 ft. 2½ in., rubber lined, cotton, fire hose; Schedule No. 1767, 1000 ft. 12½ in. engineers department hose, 1000 ft. bright finish, brass, wood hose.

Vt., Middlebury—The Hortonia Power Co., Gryphon Corner Bldg., Rutland, is having plans prepared for the erection of a 1-story, 28 x 90 ft. power house here. Grover & Connor, Rutland, Engrs.

Vt., Springfield—The Colonial Light and Power Co. has had plans prepared by W. S. Barstow Co., Inc., Engr., 50 Pine St., New York City, for the erection of a substation, garage, etc. G. F. Sanderson, Supt.

Mass., Boston—The U. S. Government plans to build a power plant. Estimated cost, $35,000.

Mass., Grafton—The State Commission on Mental Diseases is in the market for a new boiler to cost $8000; also setting up and connecting same with a battery and into the stack to furnish light, heat and power.

N. Y., Brooklyn—The Edison Electric Co., 360 Pearl St., has had plans prepared for alterations and additions to its 1-story power house on Gold St. G. L. Knight, 13 Willoughby St., Arch.

N. Y., Brooklyn—The Kings County Electric Light and Power Co., 360 Pearl St., has applied to the Public Service Commission for permission to issue $1,000,000 bonds; the proceeds will be used to build additions and make improvements to its plant. W. F. Wells, Gen. Mgr.

N. Y., Dunkirk—City plans to install a new lighting system in the business section. Estimated cost, $5000.

N. Y., Jamestown—The Crescent Tool Co., 200 Harrison St., soon receives bids for a 1-story, 100 x 200 ft., power house on Harrison St. Estimated cost, $200,000. Equipment including 1500 kw. gas driven generators and 1500 kw. steam turbine driven generators will be installed. F. A. Shoemaker, Builders Exchange, Buffalo, Engr. Noted Apr. 9.

N. Y., Mohawk—W. W. Wotherspoon, Supt. of Public Works, Capitol, Albany, is having plans prepared for the erection of hydraulic power plants under Barge Canal Contract No. 176.

N. Y., Utica—The Adirondack Power Co., Glen Falls, plans to build a power house near here. Estimated cost, $100,000. W. A. Buttrick, Glens Falls, Mgr.

N. J., Mountain Lakes—The Board of Education, Hanover Township, plans to install a new heating system in the local school building.

N. J., Plainfield—The International Power Corporation plans to build a power plant in Freeville near here.

N. J., Trenton—The Crescent Insulated Wire and Cable Co., Olden and Taylor St., will soon receive separate bids for an entire steam heating system, electric elevator and electric lighting system. Peuckert & Wundr, 310 Chestnut St., Philadelphia, Arch.

Penn., Birdsboro—The E. & G. Brooke Iron Co. plans to build a 6 mi. electric transmission line from here to iron and copper mines at Elverson to supply current for the electrical equipment used in the mine.

Md., Myersville—City plans to install an electric lighting plant and a water-works system.

Ga., Dallas—The Dallas Utility Co., recently incorporated, plans to install an electric power plant on Pumpkin Vine Creek, Paulding County. J. S. Boges, Mgr.

Ohio, Bryan—The Village plans to expend about $10,000 for extensions to its electric lighting and water-works systems.

Ohio, Cleveland—City has had plans prepared by the City Engineer, for the construction of a 3-story, 169 x 175 ft. electric lighting plant. Estimated cost, $256,000.

Ohio, Cleveland—The Steel Products Co., 2196 Clarkwood Rd., has had plans prepared for the erection of a 1-story, 50 x 60 ft. heating plant to be erected on Cedar Ave. Estimated cost, $50,000. Burchard, Roberts & Wales, Engr., 622 Swetland Bldg., receives bids until May 18. Noted Apr. 16.

Ohio, East Cleveland—(Cleveland P. O.)—The Board of Education, Shaw High School Bldg., plans to install a low pressure boiler for steam heat, also a central heating plant in Technical High School on Prospect Ave. W. H. Nicklas, Engr., 1900 Euclid Ave., receives bids for same.

Ohio, East Liverpool—City is receiving bids for the installation of a new lighting system on Main St. from 3rd to 18th St.

Ohio, Holgate—The Pleasant Light and Water Co., recently organized with $10,000, will take over the municipal plant and install additional equipment in same.

Ohio, Springfield—The Springfield Light, Heat and Power Co. has petitioned the State Utility commision for authority to issue $100,000; the proceeds will be used to purchase boilers and mechanical equipment.

Ind., Connersville—The Rex Manufacturing Co. has had plans prepared for the erection of a 1-story, 58 x 120 ft. power house. E. C. Bacon, Engr., 617 Merchants Bank Bldg., Indianapolis, is receiving bids for same.

Mich., Flushing—The Hart Milling and Power Co. is having preliminary plans prepared for the erection of a power plant, pumping station, etc. L. T. Sayre, Pres.

Wis., Brodhead—The City Council will receive bids until Apr. 30 at the office of R. F. Leger, Attorney, for the erection of a brick power plant. Noted Apr. 9.

Wis., Cedarburg—The Cedarburg Canning Co. has had plans prepared for the erection of a 2-story 20 x 80 ft. boiler and storage room addition to its plant. Estimated cost, $10,000. W. F. Helgen, Arch.

Wis., Fond du Lac—The F. Rueping Leather Co. is having preliminary plans prepared by E. Kottke, Engr., for the erection of a power plant.

Wis., Sheboygan—The Badger State Tanning Co., 3 Water St., has had plans prepared for the erection of a 1- and 2-story, 76 x 130 ft. power house, machine shop, etc. Juul & Smith, Engr., 805 North 8th St., receiving bids. Noted Jan. 22.

Wis., Superior—The Superior Iron Works, 3rd St. and Grand Ave., plans to build a 2-story, 60 x 96 ft. boiler shop. Estimated cost, $5,000.

Iowa, Keokak—The E. I duPont de Nemours Co., Wilmington, Del., is improving and building an addition to its power plant at Mooar. Estimated cost, $200,000. C. K. Weston, Wilmington, Publicity Agt.

S. D., Sherman—Bim Bros. has been granted a franchise for an electric lighting system.

Tex., Bremont—The Calvert Water, Ice and Electric Light Co., Calvert, plans to install an electric lighting system here and extend its transmission line from here to Calvert. A. E. Stoltz, Calvert, Ch. Engr.

Okla., Prague—City voted $15,000 bonds for electric lights. Noted Feb. 5.

Okla., Yale—City election soon to vote on bond issue for electric lights

Que., Montreal—O P. Tremblay, 291 Prud 'Homme Ave., Notre Dame de Grace, is in the market for 20-25 hp. electric motor and three 7 or 2-10 hp. transformers.

Ont., Sudbury—The Water and Light Committee is in the market for an electric pump with 12,000 gal. capacity and a 175 hp., 2 phase induction, direct drive, 220 volts, a.c. motor. W. J. Rose, town clk.

Ont, Toronto—The Veterinary Specialty Co., Ltd., 1595 Dundas St., W., is in the market for a 100 hp. boiler, a 75 hp. engine and 1-ton power elevator.

Man., Winnipeg—The Board of Control plans to build a gas plant here. Address A. Puttee, Controller.

B. C., Nelson—The Town plans to build an electro melting plant. A. Thomas, city engr.

CONTRACTS AWARDED

Mass., Boston—The New York, New Haven and Hartford R.R., New Haven, has awarded the contract for the erection of a 1-story, 20 x 140 ft., electric battery building, C. W. Murdock, 185 Church St., New Haven.

Mass., Cambridge—The Cambridge Electric Light Co., 46 Blackstone St., has awarded the contract for the erection of a 1-story, 44 x 69 ft. addition to its boiler house, to the J. F. Griffin Co., 17 Milk St., Boston. Estimated cost, $20,000.

Mass., Springfield—The United Electric Light Co., 73 State St., has awarded the contract for improvements to its plant, to Stone & Webster, 147 Milk St., Boston. Estimated cost, $300,000. Work includes installation of new switching equipment throughout the plant; also a 25,000 hp. steam turbine.

N. Y., Brooklyn—The U. S. Government has awarded the contract for a 1-story, 48 x 80 ft. steel power house to be erected at the Navy Yard, here, to the Westinghouse, Church, Kerr Co., 37 Wall St., New York City.

N. Y., Rochester—The Board of Contract and Supply has awarded the contract for the erection of a power plant, to A. Friederich & Sons Co., 710 Lake Ave.

N. Y., Yonkers—The National Sugar Refining Co., Main St., has awarded the contract for the erection of a boiler house, to Lynch & Larkin, 127 Downing St. Estimated cost, $40,000. Noted June 26.

N. J., Newark—The Northern Leather Works and Produce Co., Inc., 377 Broadway, New York City, has awarded the contract for the erection of a power house, to H. W. Franklin, 110 Fort Green Pl., Brooklyn.

Penn., Allentown—The Allentown Bethlehem Gas Co., a subsidiary of the United Gas Improvement Co., Broad and Arch St., Philadelphia, has awarded the contract for the erection of a generator and boiler house addition, to the Ochs Constr. Co., 442 Wire St.

Penn., Grove City—The Grove City Creamery Co. has awarded the contract for the erection of a 3-story power plant, to Rose & Fisher, 1719 Pennsylvania Ave., Pittsburgh. Noted Oct. 23.

Penn., Philadelphia—The Atlantic Refining Co., 3144 Passyunk Ave., has awarded the contract for alterations and improvements to its power house, to Metzger & Fisher, Otis Bldg. Estimated cost, $11,300.

Md., Linthicum—The Consolidated Gas, Electric Light and Power Co., Lexington St. Bldg., Baltimore, has awarded the contract for the erection of a 26 x 40 ft. addition to its power station, to the Coggswell Koether Co., 406 Park Ave., Baltimore. Noted Mar. 26.

Va., Norfolk—The Virginia Railway and Power Co. has awarded the contract for the erection of a 1-story, 50 x 100 ft substation, to Nicholas & Linderman, Seaboard Bank Bldg. Estimated cost, $11,700. Noted Oct. 7.

W. Va., Parkersburg—The Parkersburg Iron and Steel Co. has awarded the contract for the erection of a 1-story, 30 x 42 ft. power house, to the Rust Eng. Co., Farmers Bank Bldg., Pittsburgh, Penn. Estimated cost, $12,000.

Ohio, Alliance—The Dougherty Operating Co. is building a large plant here to supply current to two cities. Estimated cost, $2,225,000. M R. Bunt, Ch. Engr.

Ohio, Lorain—The American Ship Building Co. is building a large power plant here. Estimated cost, $200,000.

Ill., East St. Louis—B. Gratz, c/o the American Manufacturing Co., 1026 South 11th St., St. Louis, Mo., has awarded the contract for the erection of a 1-story, 51 x 88 ft. power plant, to L. H. Gron, Benoist Bldg., St. Louis, Mo. Estimated cost, $40,000. Noted Dec. 4.

Wis., Eau Claire—The Eau Claire Boiler and Laundry Co. has awarded the contract for the erection of a boiler house and laundry, to The Hoeppner and Bartlett Co.

Minn., Duluth—The McDougall Duluth Shipbuilding Co., 15th Ave., has awarded the contract for the erection of a large boiler shop, to McLeod & Smith, 705 Sellwood St.

Ore., Portland—The Northwestern Electric Co. has awarded the contract for the erection of an auxiliary steam plant, to C C. Moore & Co., San Francisco, Cal.

Calif., Richmond—City has awarded the contract for furnishing a 5-ton electric crane at the wharf, to the Cyclops Iron Works, 837 Folsom St., San Francisco, cost, $75,000; furnishing an electric motor, to the United Electric Vehicle Co., 1239 Sutter St., San Francisco, $4383.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 18, 1918	Individual Apr. 18, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Apr. 18, 1918	Individual Apr. 18, 1918
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Apr. 18, 1918	One Yr. Ago	Apr. 18, 1918	One Year Ago
Pea	$3.45	$2.80	$4.35	$3.70
Barley	2.15	1.50	2.40	1.75
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net tou f.o.b. mines are as follows:

	Williamson and Franklin Counties April 18, 1918	Mt. Olive & Staunton April 18, 1918	Standard April 18, 1918
6-in. lump	$2.65-3.00	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg	2.65-2.80	2.35-2.50	2.25-2.40
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut	2.65-3.00	2.65-2.80	2.65-2.80
2-in. screen	2.15-2.40	2.15-2.40	2.15-2.40
No. 5 washed	2.15-2.30	2.15-2.30	2.15-2.30

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, APRIL 30, 1918 No. 18

Combustion of North Dakota Lignites With Suggestions for Design of Furnaces

By HENRY KREISINGER
Engineer, United States Bureau of Mines

Convinced that those adjacent to the great lignite fields should learn how best to use this fuel and not draw upon the coal from distant mines, "Power" some time ago requested Dr. Manning, of the Bureau of Mines, to permit Mr. Kreisinger to write for "Power" an article in which he would present the results of his investigations in the commercial use of lignites in which the West and Northwest abounds. The article is therefore published by permission of Dr. Manning, Director of the United States Bureau of Mines, and is in part from a report to be submitted to the Director. Mr. Kreisinger points out that combustion is limited to about the first three inches of the fuel bed and that the CO_2 is rapidly and completely reduced to CO at about four inches from the grate, necessitating the introduction of oxygen (air) above and against the fuel bed. Because of the heat-absorbing effect of CO_2 reducing to CO and because of the high moisture content, the flame should sweep forward over the fuel bed. The horizontal grate is unsuited to lignite, a step-grate with large air openings being best adapted. The article should help those who will burn lignite because of the Fuel Administration's zone system for the distribution of coal.

THE natural lignite of North Dakota is of a brown color and has a distinct woody structure. Approximate analysis shows it to contain 40 per cent. moisture, 25 per cent. volatile matter, 28 per cent. fixed carbon and 7 per cent. ash. The heating value of natural lignite is very low, being only about 6300 B.t.u. per pound. When exposed to weather, the moisture evaporates rapidly and the lignite crumbles into small flat pieces, or flakes. Similar crumbling also takes place, to a large extent, in the fire and is one of the chief objections to burning lignite. The high moisture content and the crumbling when exposed to weather are serious drawbacks to transportation of the lignite over long distances, thus limiting the use of this fuel to comparatively small districts around the lignite mines.

To avoid these objections attempts are being made to carbonize the lignite in coke ovens or in gas retorts and use the carbonized residue as fuel. The residue has much lower moisture and much higher heat value, and for this reason there seem to be possibilities that it could find use over wider territories. The residue analyzes about 14 per cent. moisture, 9 per cent. volatile matter, 66 per cent. fixed carbon and 11 per cent. ash. Its heating value is 10,400 B.t.u. per pound. It consist mostly of small pieces, all of which pass through ½-in. screen and about 40 per cent. through ⅛-in. screen. It is dull gray, almost black in color, and under a low-power microscope appears to be of homogeneous structure, somewhat like some of the hard bituminous coals. Its specific weight is about 0.8 that of anthracite of similar size.

Combustion Qualities of Lignite and Its Carbonized Residue

In the ordinary furnace with horizontal grate the lignite of North Dakota is very difficult to ignite. The surface of the fuel bed is rather dark and uncheerful, with flames appearing only in spots. The flames are of bluish yellow color and clean, containing little soot. The crumbling of the lignite makes a rather dense fuel bed, offering high resistance to the flow of air. Some of the small pieces sift through the grate and continue to burn in the ashpit, especially if the fire is disturbed. With careless handling of the fire so much burning lignite may be sifted through the grate that the ashpit may have more fire than the furnace. In the fuel bed the processes of combustion are largely limited to the first three inches from the grate. This is probably partly due to the compactness of the fuel bed and partly to the high activity of the carbon in the lignite. The compactness of the fuel bed breaks the current of air passing up through it into many small streams, so that the oxygen and the products of combustion come in close contact with the hot carbon. The carbon may be in such form that it combines rapidly with the oxygen and also with CO_2, which acts as an oxidizing agent. The carbon combines with the oxygen passing up through the layer next to the grate and forms CO_2. The CO_2 itself is rapidly and almost completely reduced to CO three to four inches from the grate so that at the surface of the fuel bed there is practically no oxygen and little, frequently less than 1 per cent., of CO_2. The reduction of CO_2 to CO is a heat-absorbing process, consequently a large part of the heat generated in the layer next to the grate is absorbed in the upper layers of the fuel bed by the reduction. This heat absorption by the reduction process is partly a cause of the darkness of the surface of the fuel bed. The high moisture content of the lignite causes this fuel to absorb large quantities of heat and is a further cause of the darkness at the top of the fuel bed. The processes of combustion in the fuel bed are shown graphically in Fig. 1, which shows the results of some combustion experiments made at the Bureau of Mines.

The rapid oxidation limits the high temperature to a thin zone near the grate, where most of the ashes accumulate, and because of the heat tend to fuse into clinker.

The gases rising from the fuel bed consist mostly of CO, hydrogen and light hydrocarbons, all of which are easily burned. There seem to be no, or little, hydrocarbons which are likely to decompose and produce smoke; consequently the lignite, compared with bituminous coals, can be considered as a smokeless fuel. Complete combustion is further aided by the fact that the distillation of volatile matter is nearly uniform throughout a firing cycle, provided the firings are not too far apart in point of time; the distillation being uniform, it is easy to supply the right amount of air to burn lignite completely without large excess of air. When burning lignite, there are no such high peaks of combustible gases immediately after firing, demanding large air supply, as is the case with bituminous coals; in fact, the demand for air is about as uniform as it is in hand-firing anthracite coal. This feature is shown in Fig. 2, which gives the percentages of CO_2 in the furnace gases taken at 15- to 20-sec. intervals during several firings when burning lignite, anthracite, Pocahontas and Pittsburgh coals, the length of the firing cycle being the same in all cases.

The carbonized residue, being of small size, lies compactly on the grate and offers high resistance to the flow of air through the fuel bed; high draft is required even with a 4-in. fuel bed and moderate rates of combustion. This high resistance to the passage of air is probably the greatest drawback to burning the carbonized residue on a horizontal grate. The high draft is likely to blow holes through the fuel bed and make an uneven fire.

The draft required for given rates of combustion of natural lignite and the carbonized residue is shown graphically in Fig. 3. As indicated in the figure, it is practically impossible to obtain rates of combustion of 20 to 30 lb. with a 6-in. fuel bed of the residue with a chimney draft.

BEHAVIOR OF THE FUEL BED

The activity of the carbon to combine with oxygen and CO_2 is even greater than that of the carbon in the natural lignite. The oxygen passing up through the grate is all consumed in burning the carbon to CO_2, and the CO_2 reduced to CO in the first two or three inches above the grate; the upper layers in the fuel bed remain practically inactive. The reducing process keeps the gases comparatively cold and the top of the fuel bed dark, unless the rates of combustion are increased beyond 30 lb. On ordinary grates such high rates of combustion would require high draft. When the rate of combustion of about 40 lb. of fuel per square foot of grate per hour is approached, there is started a strong agitation in the fuel bed; the particles of fuel are moving so that the whole surface of the fuel bed appears like a boiling liquid. When this stage is reached, further increase in the rate of combustion is not accompanied by a proportional increase in the draft required to produce this rate of combustion. This is shown in Fig. 3, particularly by the curve for carbonized residue for a 6-in. fuel bed.

The high temperature resulting from the intensified combustion near the grate tends to melt the ash into clinker. The clinker is dense and impervious to air, and it is doubtful that rates of combustion between 20 and 30 lb. could be maintained more than two or three hours before it would be necessary to remove the clinker. The clinkering tendency is aggravated by the fact that on account of the small size of the fuel, a grate with small air spaces must be used, the air spaces not being sufficiently large to insure continual riddance of ash. The main cause of the clinkering is the low fusing temperature of the ash, which is only about 2000 deg. F.

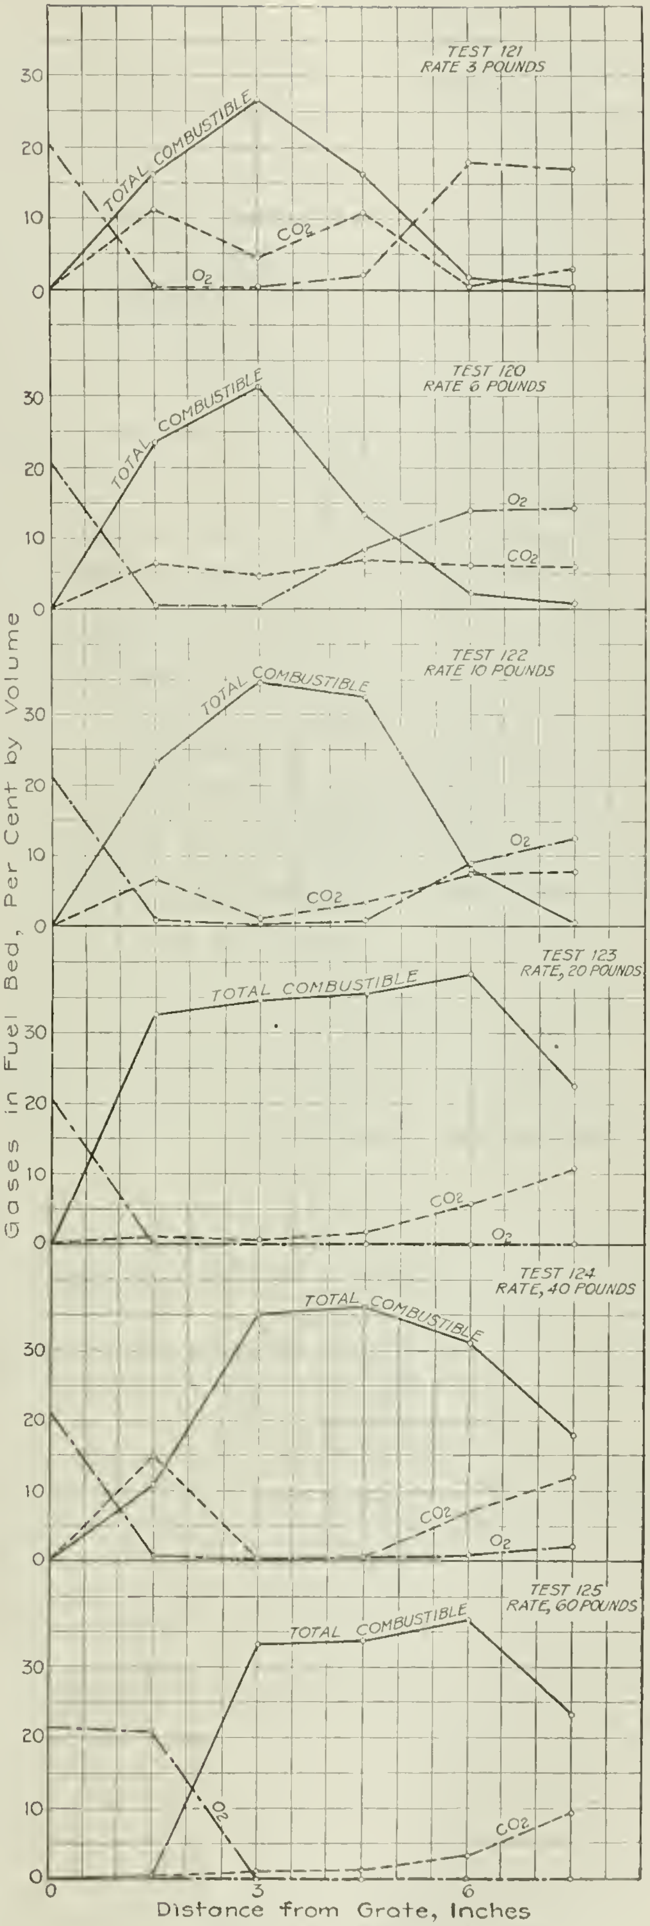

FIG. 1. RESULTS OF COMBUSTION TESTS

The gases rising from the fuel bed contain a large percentage of combustible gas, mostly CO, with no oxygen and practically no CO_2. Judging by the rapidity of the reactions in the fuel bed, it would seem that the natural lignite, as well as the carbonized residue, would make a good fuel for gas producers, the tendency to clinker, of course, being the only drawback to this fuel for this purpose.

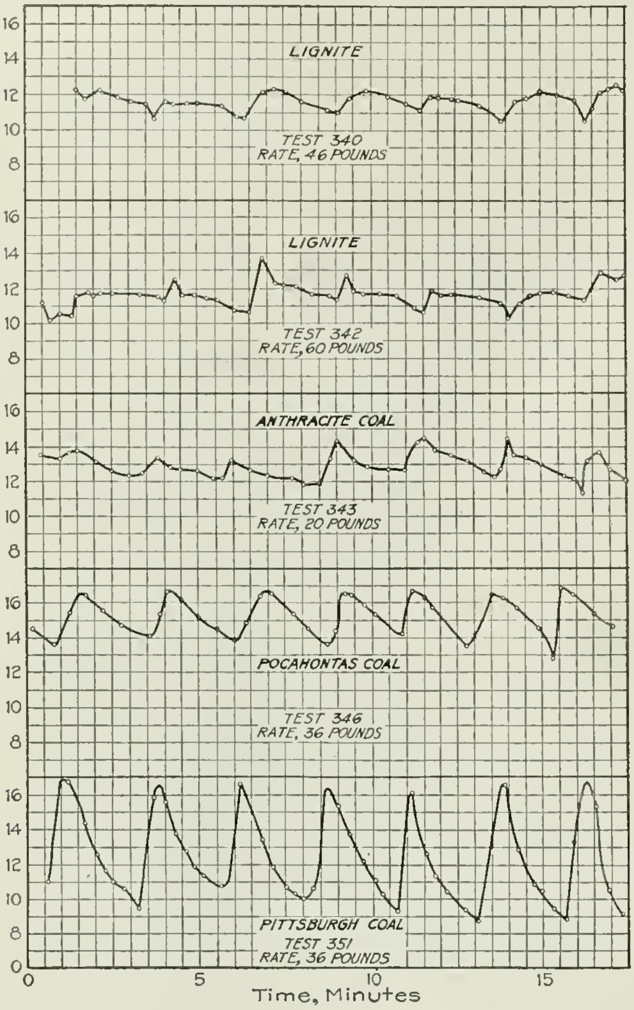

FIG. 2. CO_2 WITH VARIOUS FUELS

REQUIREMENT OF A FURNACE FOR BURNING LIGNITE AND ITS CARBONIZED RESIDUE

Any furnace that will burn the lignite and its carbonized residue successfully must fulfill the following conditions: It must have a provision for rapid ignition; it must supply enough air with ordinary draft to produce a reasonably high rate of combustion and make a hot fire; it must have a grate of such design that will prevent sifting of combustible into the ashpit and at the same time permit of cleaning the fire without impairing its function. A special furnace was designed and constructed in accordance with these requirements and with particular application to house-heating purposes. The essential features are shown in Fig. 4.

Rapid ignition is obtained by the rear arch, which turns the hot gases and flames back over the fuel bed. Thus, the incoming fresh fuel is heated not only by conduction through the fuel and radiation from the arch, but mainly by convection by coming in contact with the hot gases and flames from the already burning fuel. If a long front arch is used with no rear arch, the flames and hot gases flow away from the incoming coal and the fire has a tendency to be moved from under the arch and extinguished.

To heat lignite having 35 per cent. moisture to ignition temperature takes more than twice as much heat as is required to heat bituminous coal containing 10 per cent. of moisture. It is therefore difficult, if not impossible, to supply enough heat by radiation from the ordinary front arch to ignite the lignite. The rate of heat transmission by radiation depends almost entirely on the temperature. Therefore, to supply more than twice the heat by radiation from the arch would require that the arch be kept at considerably higher temperature when burning lignite than when burning ordinary bituminous coal. But with lignites it is not possible to obtain temperatures nearly as high as with bituminous coals. Therefore, it is plain that another factor in the heat transfer must be brought into action, and that is the heat transmission from the hot gases by convection.

The grate is inclined and has wide horizontal air spaces which can be easily kept open, permitting free flow of air through the grate. Additional air is admitted through the clinker-removing door at the lower end of the grate. As this air passes up between the arch and the fuel, it scrubs against the surface of the fuel bed and a large part of it is used in burning or gasifying solid fuel, thus making it unnecessary to force all the air needed for the gasification of the fuel through the fuel bed.

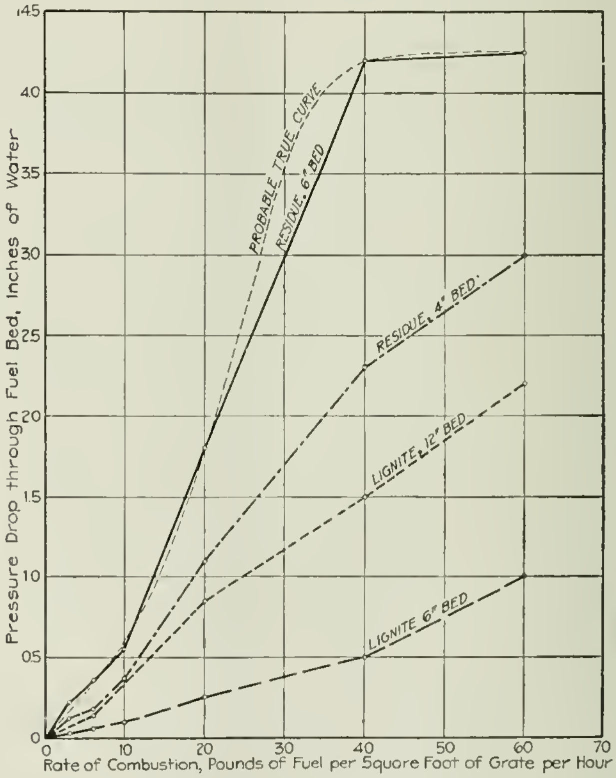

FIG. 3. DRAFT REQUIRED FOR LIGNITE

Experiments showed that the scrubbing action of the additional air caused a rapid and a rather complete oxidation at the surface of the fuel bed, indicated by the bright-red heat, which was practically absent on the tests made in an ordinary furnace with horizontal grate. Thus, there were two oxidation zones, one next to the grate and one at the surface of the fuel bed, probably with a small reducing zone between them. Because the air which enters through the cleaning door against a low resistance burns or gasifies solid fuel, higher rates of combustion can be obtained with ordinary natural draft.

The air spaces in the grate are horizontal, and the successive steps or grate bars are overlapping in such a way that there is no sifting of the combustible into the ashpit. The inclination of the grate is such that the fuel is fed from the magazine down the grate by gravity. The rate of feeding can be increased by a slight agitation or rocking of the grate bars. The fuel does not cake, and therefore the gravity feed is not interfered with as is the case with most bituminous coals. Most of the ash slides down the step grate with the fuel and finally reaches the horizontal portion of the grate, after most of the combustible has burned off. The horizontal part of the grate has small air openings through which the ash can be shaken into the ashpit. Any clinker that accumulates on this horizontal portion of the grate can be removed through the door provided for this purpose or by dumping the grate, without disturbing the fire on the inclined grate.

The thickness of the fuel bed, and to some extent the rate of feeding, are controlled by the opening of the gate of the fuel magazine.

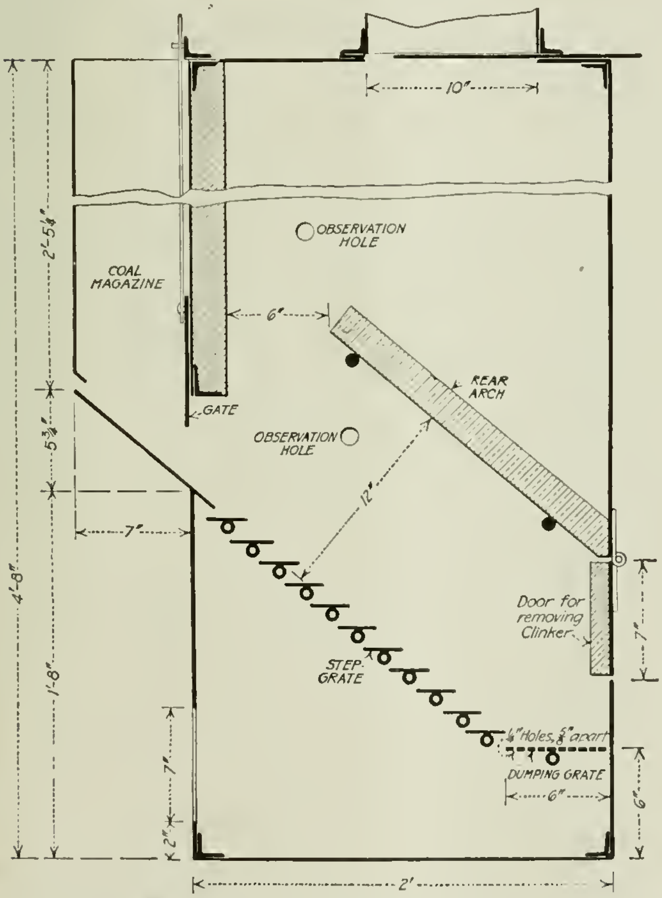

FIG. 4. EXPERIMENTAL HOUSE-HEATING FURNACE FOR LIGNITE

A fire was started in this furnace by building a small wood fire on the horizontal portion of the grate and covering the inclined portion with a bed of lignite about four inches thick. As the flames from the wood fire passed over the bed of lignite, they set it afire, so that in less than an hour the lignite over the entire grate was burning. With a draft of 0.1 to 0.15 in. of water, the lignite made a bright, red-hot fire, although the arch never became visibly red-hot. There seemed to have been considerable combustion at the surface of the fuel bed, due to the air entering through the cleaning door and scrubbing the surface.

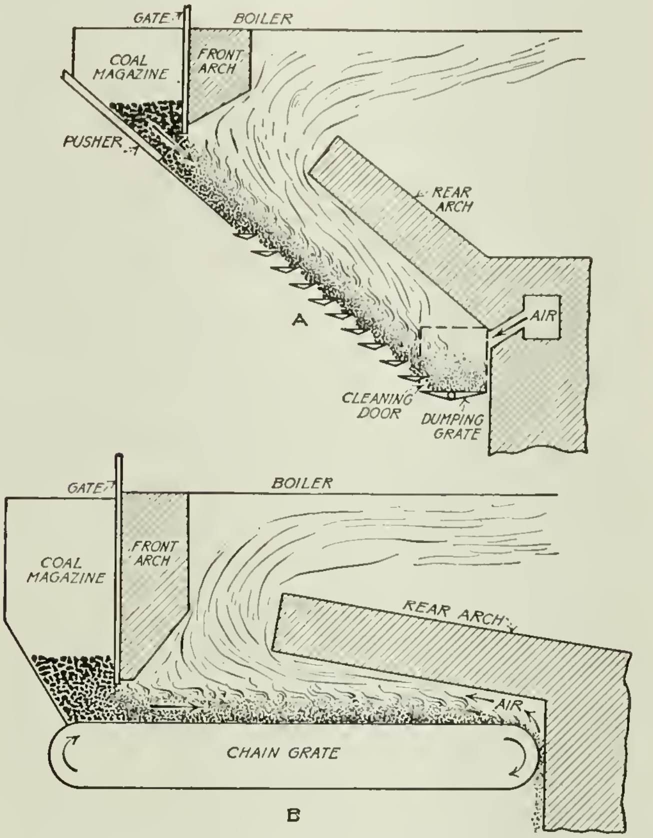

FIG. 5. PROPOSED ROUGH DESIGNS OF FURNACES FOR BURNING LIGNITE UNDER BOILERS

When the lignite was broken to pieces not exceeding about two inches, the feeding of the fuel was nearly automatic. With larger pieces the fuel had to be occasionally moved down by moving the grate bars or by poking the large pieces through the magazine gate. The fuel contained a considerable amount of slack, which, however, did not seem to cause any particular trouble. Some clinker was found on and near the horizontal portion of the grate. This clinker was very porous and floated in the free ash without touching the grate, and seemed to have been formed near the surface of the fuel bed. It was removed by hooking it out from the horizontal portion of the grate, and the fine ashes were shaken through.

The carbonized residue, on account of its uniform size, flowed down the inclined grate without any help and made a rather intense fire wholly out of comparison with the sluggish fire that could be obtained on a horizontal grate. In fact, it seems that the carbonized residue, when burned in this special type of furnace, would make an ideal fuel for house-heating purposes.

The principles embodied in the design of the special furnace shown in Fig. 4 can be applied to boiler furnaces with a promise of success. Fig. 5, diagram *A*, suggests the design of an inclined step-grate boiler furnace. The fuel can be fed down the grate by gravity aided by hand regulation, or it can be pushed out of the magazine mechanically by a pusher plate. The horizontal air spaces between the step-grate bars can be kept open easily by hand poker or by rocking the grate bars. The clinker can be removed through the side cleaning door, or it can be dropped by the dumping grate. The fine ashes accumulate on the dumping grate through which they can be shaken into the ashpit. The air is admitted through the horizontal air spaces between the step-bars of the grate and through the special openings at the end of the grate. Probably two-thirds to three-fourths of the air needed for combustion should be introduced at the end of the grate, so that as the air passes between the fuel bed and the arch it scrubs over the surface of the fuel bed and burns the coal. This air enters the furnace against a very small resistance, therefore a comparatively small draft may bring large quantities of air into the furnace and produce a fairly high rate of combustion. The air entering through the air spaces between the grate bars has to pass through the fuel bed against a comparatively high resistance, and it would require high draft to supply enough air to gasify the solid fuel.

Air Admission to the Fuel Bed

There should be as little air as possible entering through the coal magazine or through the plate in front of the coal magazine, where the fuel is merely being dried and does not burn. The completeness of combustion should be controlled by regulating the air admitted at the lower end of the grate and not by regulating the admission of air through the magazine. The air admitted through the magazine does not help in burning solid coal, but merely assists in burning the gases rising from the lower portion of the fuel bad. The gases rising from a fuel bed of lignite consist mostly of carbon monoxide and hydrogen, which are comparatively easy to burn, so that the flames would not extend too far beyond the top of the arch. The comparatively narrow space between the rear arch and front arch would help in bringing the air and combustible gases together, and cause intimate mixing. There would probably be a considerable amount of the fluffy ash carried with the gases. As soon as the gases pass beyond the contraction between the two arches, they expand and their velocity slows down, causing the ash to be deposited on top of and beyond the rear arch; so that comparatively little ash would be carried into the boiler.

The special openings for introducing air at the end of the grate would not fuse over because they do not come in contact with the hot gases and the slag which the gases contain.

Diagram *B*, of Fig. 5, shows the application of the principles to a chain grate. The diagram shows the grate in horizontal position, but it is believed that better results could be obtained if the top of the grate were inclined about 20 deg. to the horizontal.

The motion of the grate feeds the fuel into the furnace, and the thickness of the fuel bed is controlled by the opening of the gate. The air needed for combustion is introduced through the openings in the grate bars and in the rear of the grate where the ashes are discharged into the ashpit. In this case the air which enters the furnace between the end of the grate and the bridge-wall is used to burn the solid fuel on the grate as it is made to pass between the arch and the fuel bed toward the front of the grate, and therefore helps both in the rate and the completeness of combustion, and is not detrimental to efficiency, as it is with the ordinary chain-grate furnace.

Provisions should be made to stop the admission of air through the coal magazine and through the front part of the grate, where the lignite is being dried. When burning lignites, it is improbable that the furnace temperature will be high enough to injure the arch. With the CO_2 (carbon dioxide) averaging between 13 and 14 per cent., the furnace temperature will not exceed 2200 deg. F., and with the top of the arch exposed to radiate heat to the boiler above it, the arch would probably never get above 2000 deg. F. There are plenty of refractory materials that will hold under such temperatures. When burning carbonized residue, which does not contain such a high percentage of moisture as natural lignite, higher temperatures might be obtained. If these temperatures would be too high for the material in the arch, the latter could be constructed of special tiles suspended from water tubes, which could be made a part of the boiler. Similar construction is used on arches in locomotive furnaces. It should be borne in mind that, since the arches are inclined, only the horizontal component of the weight of the arch acts in pulling the arch down.

These furnaces can probably be used for burning other low-grade fuels that are difficult to ignite.

Something About Pumps

One Saturday afternoon as Willis was on his way home after shutting down for the week's end, he dropped into the engine room of the Stahley Manufacturing Co.'s plant, where an engineer by the name of Williams was in charge. He found Williams working on a pump that was used for returning the water of condensation to the boilers, and a much disgusted person he was at that particular instant.

"How is she coming," asked Willis, as he moved over toward the pump. "You seem to be up to your eye-teeth in trouble this afternoon."

"Trouble's no name for it. Here I am stuck for the day, while the rest of the fellows are off until Monday morning, just because this blamed pump won't work any better than a dog's front legs when it comes to scratching fleas."

"Well, a little thing like a pump should not keep you here very long. What seems to be the matter with it first and last?"

"She won't handle the hot water for a cent. I don't know what's the matter with the dum thing."

During this little conversation Willis had been inspecting the rings of packing that Williams had removed from the water end of the pump and discovered that they were designed for cold water and not at all fitted to pump hot water such as the pump had been handling.

"Where did you get this packing," he asked as Williams straightened up to get the kinks out of his back. "Get it at a rummage sale?"

"No, I got it a few days ago from a fellow who said his packing was just as good as what we had been using and a little cheaper. I fell for his line of talk and have had trouble ever since. What's the matter with the stuff? Do you know?" he asked as he noted the amused look of Willis.

"Surest thing you know," replied Willis. "This packing might be all right for cold water, but for hot water such as you are trying to make this pump handle you might just as well pack it with cheese cloth and be done with it. You put in some packing that is made to work with hot water and I calculate the pump will get down to business in no time. Williams," said Willis, "you can make up your mind to one thing if not another, and that is that when a machine won't do its work there is a good reason, and when it has been working all right for a spell and then suddenly goes wrong, you can gamble that some simple thing has taken place that can be easily remedied. The best thing a fellow can do in such a case is to think a little and see if he hasn't done something that might be responsible for the trouble.

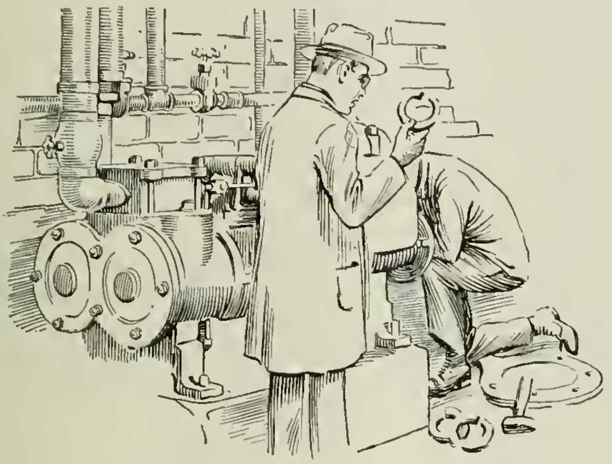

FIG. 1. "WHERE DID YOU GET THIS PACKING?"

"Now in your case if you had got in a think or two you would have come to the conclusion that something must have happened to the packing, seeing it was the only thing on the pump that was different from the regular state of affairs, and then you would have found, if you had read the label on the box, that the packing was not the kind for the work. Of course you can generally tell by the looks of a packing what kind of water it will handle, although it might be a little difficult in some cases, but this box is plainly marked 'For use with cold water,' as I have observed since I dropped in here. Now I didn't mean to preach you a sermon, but carelessness usually is responsible for most of our troubles and don't you forget it."

"Maybe, maybe," answered Williams, "but that ain't always the case, not by a long shot."

"I never told you about Silas Wetherbee, did I? Well, Silas had a new pump come one day, and after he had got it piped up as spruce as a young feller going courting for the first time, he started it up and the pump was as dry as a one-year old brindle bull. All the prominent engineers around about were called in to set matters right, but although the pump piston would shoot back and forth there wasn't any water coming out of the discharge pipe.

"The pump was of good make; in fact, Silas had another one that had never given any trouble, and he couldn't imagine why the new one wouldn't pick up and go on about its business the same as any decent pump should.

"As it happened, I strolled into the plant when about everyone had condemned the pump to the hottest place they could think of and Silas asked me to try my luck at it. He told me about every thing that had been done to get it started, and I decided there wasn't any use in going over the same road the others had traveled.

"Well, to make a long story short I got Silas to break the suction pipe pretty close up to the pump and then got a pail of water and stuck the short end of the suction pipe in it. Silas started up the pump and that water disappeared quicker than you can say scat. We tried it again and the same thing happened, and I told Silas I calculated that if the pump could get water there wouldn't be any trouble about its throwing a stream out of the discharge pipe to wherever he wanted it to go."

"What was the matter with the pump that it wouldn't take water? Another case of using packing that wasn't fit for the work?"

"Nothing of the sort. The dom idiot had connected the suction pipe to an old one that ran to a pond a little distance away, but which for some reason or other had been abandoned and the suction end left about a foot above the water. Naturally, the water wasn't going to make no hop, skip and a jump that distance into the suction pipe just to please Silas or anyone else.

"Silas said the cigars were on him, and I guess they were for I never saw any of them. However, that little incident goes to show that a feller can put up an awful holler when the fault is his own."

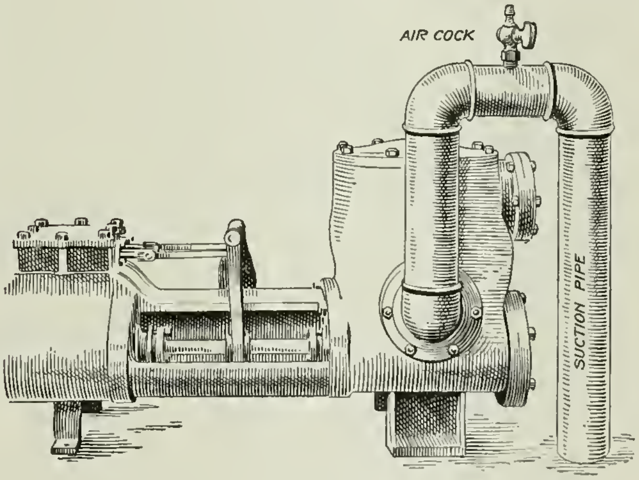

FIG. 2. "WE PUT A PET-COCK IN THE SUCTION PIPE"

"I don't see why anyone would pipe up a pump to an old suction pipe without knowing whether it was in good condition or not."

"You wouldn't think it any more than that a fellow would use cold-water packing to pump hot water," answered Willis with a grin.

"Sometimes a fellow gets a surprise when a pump won't work. I remember some years ago in one plant where I worked a large pump that was used only occasionally was always supposed to be in good condition. The suction pipe was fitted with a foot valve, and it had always worked to perfection. One day I wanted that pump in a hurry, and when steam was turned on there was nothing doing.

"Naturally, I went over the thing and could find nothing out of order. Finally, the foot valve was examined, when we found that the pump valves were dry and the cause of the trouble was discovered to be due to leaves that had lodged against the foot valve and so prevented water from getting up into the pump. Of course the pump had run down, which accounted for the dry valves.

"Foot valves have caused me some trouble, but on the whole I take it that they are better than nothing on the end of the pipe, as they keep fish, eels and other rubbish from getting into the pipe. I always have 'em on my suctions unless the water is coming from a well where there is but little danger of the pipe taking anything large enough to get stuck in the pump valves."

"Yep, I know," answered Williams, "but just the same that foot valve came off the pipe and mighty quick at that. I don't see what there was to prevent the pump from running down without the foot valve just as easily as it did with it on and the clapper stuck open."

"If you will only give me a chance, I'll tell you what was done. You see, we ran the suction pipe up to a point a little above the top of the pump-valve deck and then capped it with an elbow in which a long nipple was screwed. On the other end of the nipple another ell was fitted and the other end of it was fitted to a pipe that connected with the pump. This arrangement gave two legs to the suction pipe, and as the long nipple was fitted with an air valve it was an easy matter to cut the pipe into two sections, so that when the water in the pipe from the supply started to run down, the water in the pipe connected to the pump would remain where it was, and it was there when we wanted to start up. The only thing we had to remember was to open the air-cock when shutting down the pump, just to cut the water into two separate bodies."

"Well, I suppose pumps are necessary about a steam plant, but I wish that someone would get up something that would work without valves and pistons in handling hot-water returns. Then there would be less gloom, for me at least. A pump is a nuisance anyway."

"Why, Williams, you don't mean to say that you don't know of a way to get your returns back into the boiler without a pump, do you? Didn't you ever hear of the return loop? No? Well, I ain't got the time to tell you about it just now, as I have got to get home so as to keep peace in the family; but the next time I get a chance I'll drop in and give you a few pointers on the loop that may come in handy some time or other. Now I guess I'll meander along and see what the old lady's got for dinner."

Whitewash and Fire-Retarding Mixture

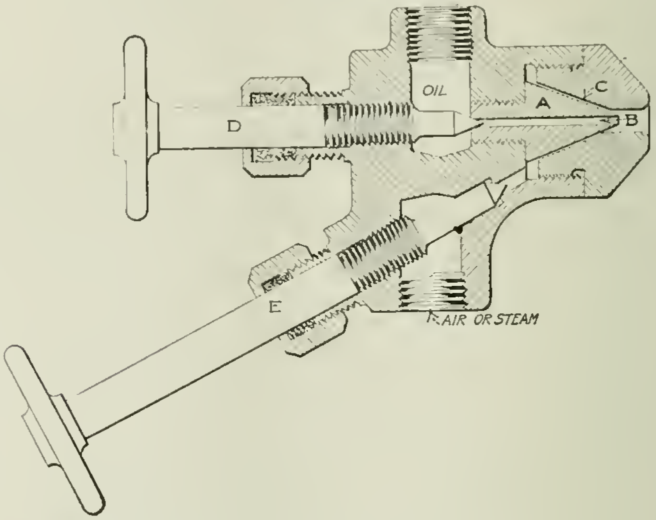
Following is the formula for what is known as the United States Government whitewash mixture, which also acts as a fire-retarding coating over interior wooden surfaces: Slake ½ bushel of quicklime with boiling water, keeping it covered during process; strain and add 1 peck of salt dissolved in warm water; put 3 lb. ground rice in water and boil to a thin paste; ½ lb. of powdered Spanish whiting; 1 lb. of clean glue dissolved in hot water. Mix well and let stand for several days. Keep in kettle or receptacle and apply as hot as possible with a whitewash or paint brush.

Anderson Fuel-Oil Burner

In burning fuel oil its atomization must be thorough, and in order to attain this result a proper burner must be used and the more simple its construction the better. Oil burners are of two types, inside and outside mixing. In the former the oil and steam come in contact inside of the burner and the mixture is atomized in passing through the burner nozzle. In the latter type the steam passes through a narrow slot or through a series of small holes below a similar slot through which the oil flows, the oil being picked up by the steam outside of the burner and thus atomized by it.

An oil burner of the inside-mixing type has recently been perfected by the N. C. Davison Gas Burner and Welding Co., 3145 Penn Ave., Pittsburgh, Penn.

The device consists of a central cone *A* with an oil opening *B* through the center. The oil is atomized by air or steam that is admitted through the cone-shaped opening *C* surrounding the oil cone. The air or steam crosses the oil just at the mouth of the nozzle *A* and atomizes the oil, so that immediate combustion takes place without smoke, even in a cold furnace. The flames can be cut down to 1 ft. in length or increased to as much as 18 ft. The burner is simple in construction and is easily operated. The needle valves *D* and *E* are for hand-controlling the oil and air supply respectively.



SECTION THROUGH THE ANDERSON OIL BURNER

As a matter of fact, three types of oil burners are made. The first is a straight oil burner in which air or steam is used for atomizing. For this purpose a pressure of from 30 to 100 lb. of air or steam is used and an oil pressure of from 5 to 50 lb. Then there is a combination oil and gas burner for use where gas can be had part of the time. Air for gas is supplied at from 4 to 8 oz. and high-pressure air or steam when using oil. The third type of burner is for oil when air at low pressure is used for atomizing. This air can be used at a pressure of from 6 to 10 oz. This burner is made either for straight oil burning or for a combination of oil and gas, both fuels being supplied with the low-pressure air.

These burners are suitable for use under steam boilers, with openhearth furnace-ingot and billet furnaces, core ovens and all types of down-draft kilns and ovens. Wherever coal, coke or gas is used, the burner is adaptable.

From Superheated Steam to Blast-Furnace Gas Engines

By A. L. Fritz

Converting an experienced steam-engine operator into a blast-furnace gas-engine operator cannot be thoroughly accomplished in a few days' time. From superheated steam to blast-furnace gas is a long, hard jump, and having measured the distance, so to speak, I know that it is a hard proposition.

After operating cross-compound horizontal-vertical steam engines for five years, I was suddenly transferred to a blast-furnace gas-engine room containing four 3000-kw. units, and that yellow transfer card, once it became effective, turned out to be a round-trip ticket to His Satanic Majesty's winter resort.

I was put to break in with an experienced gas-engine operator, and his only fault was his creed, for it was his personal contention that every gas engineer could find out things for himself, because that was how he got his. Such reasoning is good enough if it is not carried to extremes, but that was what he did, with the result that when I began to fight those engines alone I soon found that there were a number of little kinks in my new job that I would have to unravel, and do it mostly on my own initiative.

Of course I was told and shown how to start and stop a unit and also instructed as to the running position of the ignition under normal conditions, but I was not told anything about some of the abnormal conditions that eventually made their appearance.

Left Alone With Units in Service

After four days of breaking in, I found myself alone with three units in service and the pilot light signifying that the switchboard operator required the fourth one. This unit had been idle about eight hours, and as blast-furnace gas is very irregular, when I got started up and got the machine in phase, the needle on the indicating meter forgot to stop at its usual position, but passed it going and coming; in other words, the needle went from pin to pin, from nothing to 4000 kw. It required only about five minutes of that swinging load to make the switchboard operator a raving maniac, so to speak.

I tried to quiet the engine down by changing the air intake on the mixing chambers, but the more air levers I moved the more the engine bucked the load. With prematuring and nonexplosions it took but a short time to acquire a severe gas headache, and I began to wish someone else had my work card for the time being.

Conditions got far below anything they were used to (on account of my swinging), and to get me out of a bad hole my former instructor was called in. He made two trips around the engine, pulled his cap to one side of his head, gazed at the meter needle and it suddenly stopped its wild rampage and indicated 2800 kw. I asked the gentleman what was wrong and what he did to rectify it, and he curtly replied, "nothing."

I knew right then that he didn't carry a paid-up membership in any "Honest Jawn Club," and I also knew that it was up to me to "get onto" what I didn't know.

After weeks of hard, bitter scrambling, coupled with many a gas head, I learned to really handle the engines. During this time I learned something of the ill temper of such a machine, and it dawned on me that the gas engineer really earned his extra dollar per turn above the steam operator's rate.

My relief was an experienced operator, and although he told me very little, he always left the watch shipshape, and I acquired the blue-chalk habit. For instance, I had a chalk mark on all the air levers on the mixing chambers, and if a unit got to swinging, I could change the air; and if it didn't get results, I could put it back where it belonged. In this way I usually found the trouble before I got around to the last lever.

Locating the Cause of Trouble

Sometimes it would be a dirty brush on the ignition, a grounded ignitor, or a fuse blown out, and once in a while a unit would swing on account of too much cold circulating water. Again, it might swing on account of a shoe slipping down on a multiplying lever on an air-inlet valve; a brush-holder might work loose, letting the brush get out of line with the commutator, thus making the contact too early or too late on that ignitor and therefore causing a jerk in the load.

I gradually learned to judge conditions, and eventually I got the whip hand over the operating kinks that go to make the gas-engine log sheet look good to the "Old Man." I found out that by keeping the circulating water at a normal temperature in the pistons and cylinder jackets and a regular oil feed for cylinder lubrication, my trouble invariably dwindled down to air mixture.

It is important, in gas-engine operation, to govern the amount of lubrication closely and to be sure it is not fed hit-and-miss, but a drop in each spray to every three turns of the layshaft, for instance. Furthermore, increase the oil feed on a cylinder if it gets to backfiring very much, as backfiring causes dry spots on the cylinder walls and pistons; but do not flood a piston to remove a black spot; use a few applications of kerosene and then adjust the lubricating oil to that individual unit.

Watch the clearance on the inlet- and the exhaust-valve lifts and see that there is at least a $\frac{1}{16}$-in. clearance. Keep the gas lift equalized on all inlet valves and also keep the ignition equalized on both sides of the engine. See that the swing joints do not leak and ruin the oil circulation. Try both oil pumps every day on each unit to see that they are in order and keep the expansion joints tight.

Operator Must Learn Pulse of Engine

It is up to the operator to learn the pulse of each engine, for the natural circumstance under which a gas engine operates tends to work things loose—a great deal more so than the even pulsing stroke of a steam engine—and it pays to thoroughly inspect each unit frequently.

And last but not least, by all means cultivate the good will of the switchboard operator; cater to his professional hobbies relative to gas engines. His job is no sinecure, for gas engines make his a hard task, and if his ethics of coöperation are the least bit below par, he can make life miserable for the unfortunate who happens to be the man behind the throttle on a blast-furnace gas engine.

Current-Transformer Connections

By W. R. WOODWARD

Engineer, Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn.

A description is given of two types of current-transformer construction, and then the reverse "V" and the star connections of this type of apparatus are discussed.

CURRENT transformers are used for one or both of two purposes; namely, to reduce the current in the circuit to a value suitable for use with instruments or to insulate the instruments from the high-tension circuit. They are so designed that the secondary current is a definite proportion of the primary current for practically any value of primary current which may flow.

The current transformer is simple in construction, consisting of a primary and a secondary winding, both of which inclose a laminated iron core. The primary winding consists of a large number of turns of comparatively small wire, when the transformer is built for a low current (say 10 to 5 amperes) and of a small number of turns of heavy wire or strap when built for a large current (say 100 to 5 amperes). The secondary is usually wound for 5 amperes and has a large number of turns of about No. 12 wire.

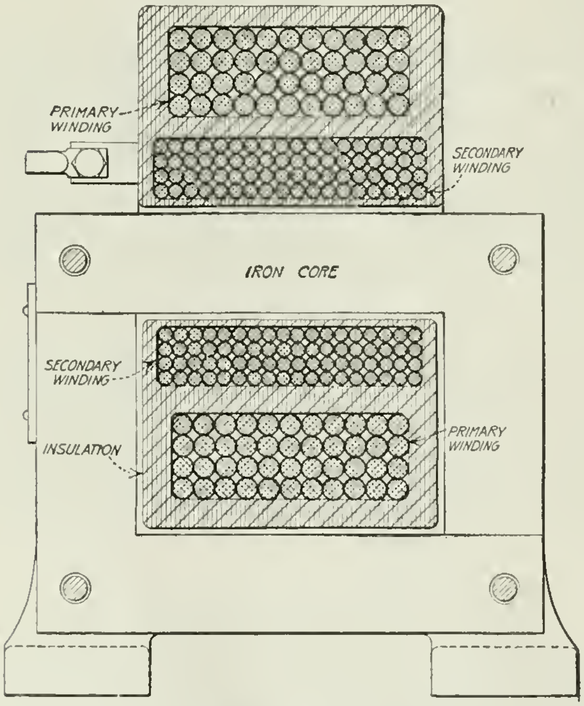


FIG. 1. SECTIONAL VIEW THROUGH A COMMON TYPE OF CURRENT TRANSFORMER

If the primary winding is to be used in a high-tension line, it is insulated from both the core and secondary winding, as shown in Fig. 1, which gives a cross-sectional view of a typical transformer. Figs. 3 and 4 are general views of the same piece of equipment. Fig. 3 is for stationary service, and Fig. 4 is a similar piece of equipment to that shown in Fig. 3, fitted with a handle to make it portable. Terminals P are the primary and S the secondary. A maximum voltage rating is usually given on the nameplate, which merely indicates the strength of the insulation, and the transformer must not be used on voltages above that rating, but may be used on any voltage below it. For instance, a transformer marked 6900 volts maximum may be used on a 2300- or 110-volt circuit, but not on an 11,000-volt circuit.

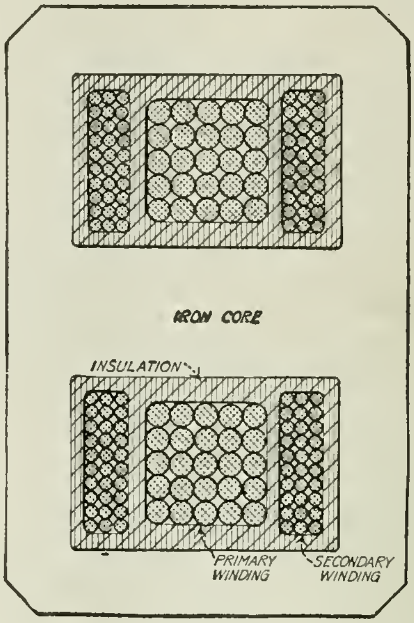

FIG. 2. SECTION THROUGH CURRENT TRANSFORMER USED FOR EITHER LOW OR VERY HIGH VOLTAGES

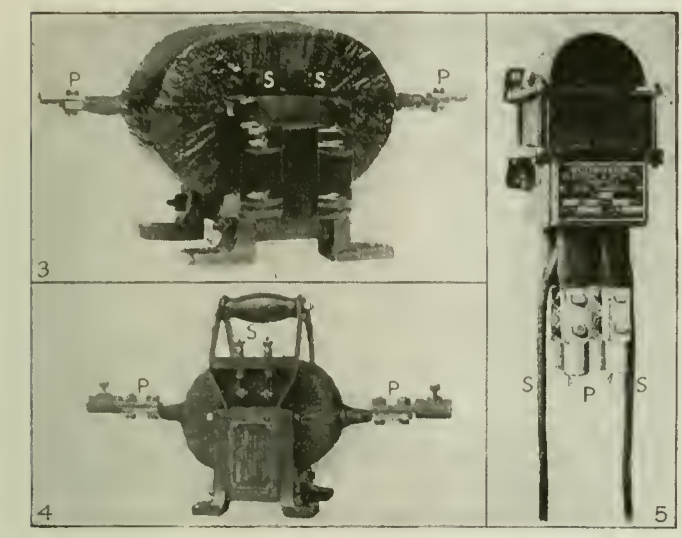
In a particular type of current transformer, such as shown in Figs. 1 and 3, the number of secondary turns is practically the same for any ratio, the only difference between transformers of different ratios being the number of primary turns and size of primary conductors.

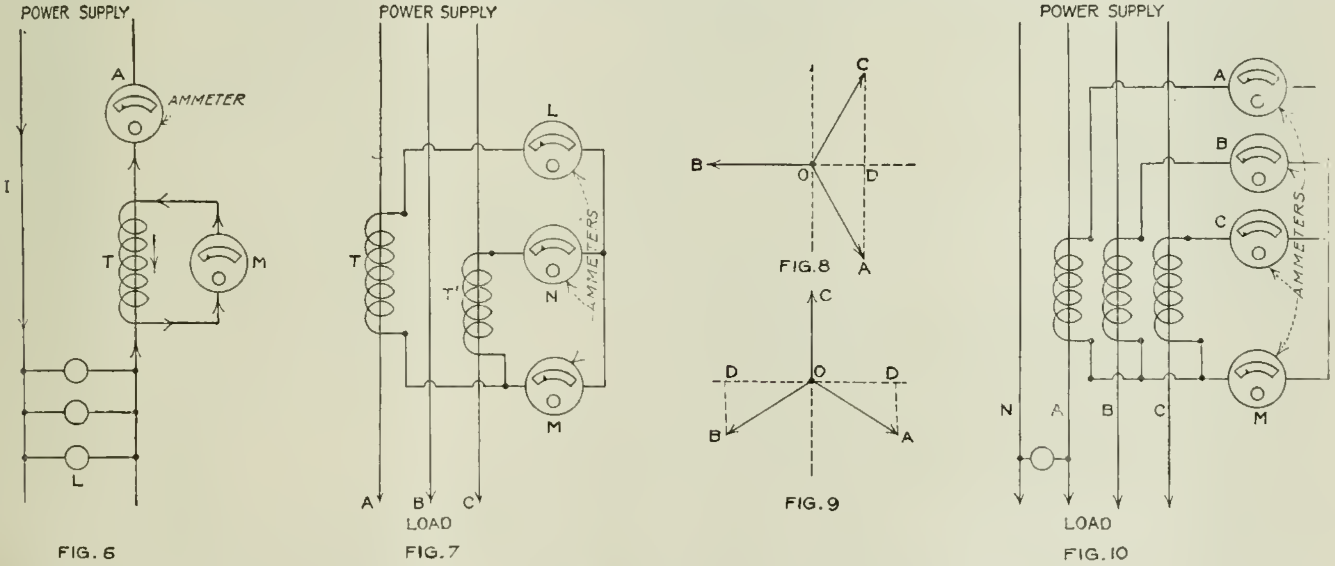
Figs. 2 and 5 are a cross-sectional view and a general view of another type of current transformer having a different arrangement of winding and core to that in Figs, 1, 3 and 4. This type is commonly used for low voltages, 2300 or less, and also for very high voltages, 33,000 and above. It is suitable only for designs where the primary leads can both be conveniently brought out from the same end of the transformer, as in house wiring, where a transformer is installed on low voltage for a watt-hour meter or for high-voltage, oil-insulated transformers. The type, Fig. 3, is better where the primary leads are arranged to come out at opposite ends and is convenient for switchboard mounting.

The action of a current transformer can best be understood by remembering that in any transformer the current flowing in the secondary winding flows around the core in a direction opposite to that flowing in the primary and that the secondary ampere-turns (current × turns) are practically equal to the primary ampere-turns. The reason they are not equal is that the primary winding also carries the exciting current. In the current transformer the proper ratio is obtained by changing the primary turns as mentioned in the foregoing, and the error due to the exciting current is reduced to a small value by working the iron circuit at a much lower magnetic density than is common practice in ordinary constant-potential transformers. The magnetic density in the iron, and consequently the exciting current and ratio value, depend upon the impedance of the meter load connected to the secondary of the transformer.



FIGS. 3 TO 5. TYPES OF CURRENT TRANSFORMERS

If a large number of meters having a high resistance or impedance are connected to the transformers, a considerable voltage is necessary to make the current flow through the meters. To develop this voltage a certain flux must pass through the magnetic circuit, which in turn requires primary exciting current or ampere-turns which are not reproduced in the secondary winding. If the number of meters be reduced, the voltage developed in the secondary winding becomes less, thereby reducing the exciting current and improving the ratio. The secondary voltage developed will always be only the amount required to force the secondary current through the meter load. If the secondary resistance be increased to infinity (that is, becomes open-circuited), the secondary voltage will rise to the maximum (that is, the iron will become saturated). This will cause the iron to heat up, and the voltage across the secondary terminals becomes very dangerous.



FIGS. 6 TO 10. CURRENT-TRANSFORMER CONNECTIONS, AND VECTOR DIAGRAMS SHOWING THE CURRENT RELATIONS OF CURRENT TRANSFORMERS CONNECTED IN A THREE-PHASE CIRCUIT

A single-phase circuit having a current transformer *T* is shown in Fig. 6, where *L* represents the load of the circuit and *I* the current flowing in the direction shown by the arrowheads at a particular instant. The meter *M*, connected in the secondary of the current transformer, has a scale marked to indicate the current flowing through the load, thereby taking account of the ratio of transformation in the current transformer. The meter *M* therefore reads exactly the same current a direct-reading meter would if connected in the line at point *A*.

The connections of current transformers on polyphase circuits are in some cases rather complicated; in this article, however, the more common connections will be considered in detail.

The most common connection for three-phase three-wire circuits is the reversed "V" connection shown in Fig. 7, in which two current transformers *T* and *T'* may be used to indicate the current in all three wires. The current from the transformer in phase *A* flows through instruments *L* and *M* and, so far as instrument *L* is concerned, is essentially a single-phase connection, therefore instrument *L* will indicate the current in the line *A*. Similarly, the current from the transformer in phase *C* flows through instruments *N* and *M*, therefore instrument *N* indicates the current in line *C*. The combination of the currents flowing through meters *L* and *N* passes through meter *M*; this will cause the latter to indicate the current in line *B*. This fact is illustrated by the vector diagram in Fig. 8.

In considering the vector diagram, Fig. 8, let it be assumed that when the arrows point to the right the current is flowing in a particular direction which will be called positive, and when the arrows are pointing to the left it is flowing in the opposite direction, or negative. When the arrows point up or down, the current will therefore be zero, and the value of current in any line will be proportional to the distance from the vertical line drawn through *O* to the point of the arrow.

The currents in the lines *A* and *C* are represented in Fig 8 as both being positive and each to be one-half their maximum value; that is, their projection on the horizontal axis, or distance *OD*. The current in line *B* is represented as being negative and at its maximum value. Now the law of electric currents, known as Kirchhoff's Law, is that at a junction of conductors, such as at *O*, the sum of the positive and negative currents is zero; that is, any current flowing into this point on one or more conductors is equal to the current flowing out of the same point on one or more other conductors. The current in *B*, being negative, flows toward the point *O*, and is, therefore, equal to currents *A* and *B*, flowing away from this point. Therefore the current in line *B* is the vector sum of the currents in the lines *A* and *C*. Now, since the currents in the instruments *L* and *N* are exactly proportional to the currents in the lines *A* and *C*, the current in *M* must be proportional to the current in *B*.

In Fig. 9 the current in *C* is illustrated as being zero, and at that instant the currents in *B* and *A* are equal. The current in instrument *N* is, therefore, zero, and since the current from *A* flows through the meters *L* and *M*, their readings are necessarily equal, which, as can be seen from the diagram, is necessarily the case, since the projections of *OA* and *OB* on the horizontal are equal.

This connection for instruments may be used for ammeters, relays, trip coils, the current coils of wattmeters or power-factor meters, and, in fact, any current carrying coil whatsoever. However, there are some objections to using this connection for protective relays and trip coils, which will be considered later in a discussion of the "Z" connection.

METER INDICATION ALSO CORRECT FOR UNBALANCED CONDITION

In the foregoing we have considered that the three-phase load was perfectly balanced. The indication of the meters, however, will be correct as well for any unbalanced condition. The worst unbalancing possible is to have a single-phase load on two wires, with no load on the third. Suppose a single-phase load is connected across wires *A* and *B*, the currents in the two legs of the circuit will then be in direct opposition to each other; that is, if the current in *A* is positive, the current in *B* will be negative and of the same value. The current from transformer *T* will flow through instruments *L* and *M*, indicating an equal load on wires *A* and *B*, and no current will flow in *N*, indicating no current in *C*.

Suppose, again, that a single-phase load is connected to lines *A* and *C*. The current from line *A* will flow through instruments *L* and *M* as before, and current from line *C* will flow through instruments *M* and *N*. These currents tend to flow through instrument *M* in opposite directions and, being equal, are canceled. Instrument *M*, therefore, indicates zero current in line *B*, which is correct.

In case of a three-phase four-wire system, it is necessary to use three transformers, which are usually connected in "Y" or star, as shown in Fig. 10. Since it is possible for some load to be connected between one phase and the neutral, such as between *A* and *N* as shown, the current on the other phases is thereby unbalanced so that it is necessary to use three transformers. With the connections as shown, each instrument being connected to a transformer in each phase, the operation is essentially the same as for single-phase. The current which flows in *A* does not necessarily flow in *B* and *C*, but a portion may be carried off on the line *N*. The instrument at *M* will indicate the value of current flowing in the neutral wire *N*.

Burning Rhode Island Anthracite

According to a report issued by the Locomotive Pulverized Fuel Co., of New York City, tests were recently made at Olyphant, Penn., with regard to the utilization of pulverized Rhode Island anthracite in comparison with Pennsylvania anthracite. The Rhode Island coal used was mined near the surface and before being prepared for the test had been lying exposed to winter weather, so that the moisture content was high.

The tests were conducted on a 465-hp. Stirling boiler that had been in regular service with pulverized Pennsylvania anthracite as fuel. About six tons of the pulverized Rhode Island coal was substituted during the regular operation of the boiler, with no changes in the furnace, feeding equipment or operating adjustments, to compare the combustion results. No difficulty was experienced and the combustion was satisfactory.

A second test was made to determine the relative combustion and boiler efficiency, under approximately the same operating conditions, with Pennsylvania anthracite bird's-eye and Rhode Island anthracite. The latter fuel burned in practically the same manner as the former, but there was a greater accumulation of ash in the slag pit. The relative properties of the two fuels may be seen from the following:

	Pennsylvania Per Cent.	Rhode Island Per Cent.
Moisture	0.92	0.42
Volatile matter	6.82	6.65
Fixed carbon	74.55	62.75
Ash	18.63	30.60
Sulphur	......	0.82
Fineness, through 100-mesh	98.00	99.00
Fineness, through 200-mesh	90.00	93.00
Heating value (calculated) B.t.u. per lb. dry coal	11,830	9,785

The comparative results obtained in the tests of the two fuels are given in the following table:

RESULTS OF PULVERIZED FUEL TESTS

	Pennsylvania Anthracite	Rhode Island Anthracite
Duration of test	Continuous	4 hr. 20 min.
Average boiler pressure, gage	141 lb.	140 lb.
Factor of evaporation	0.978	0.991
Horsepower developed	460	386.5
Weight of fuel used	46,096 lb.	8721 lb.
Weight of water evaporated	388,356 lb.	58,300 lb.
Actual evaporation per pound of coal	8.42 lb.	6.68 lb.
Equivalent evaporation from and at 212 deg. F. per pound of coal	8.24 lb.	6.62 lb.
Boiler efficiency, per cent	67.3	65.65

The Rhode Island coal used in the tests was some of the byproduct from mine operations on a tract of graphitic anthracite, which is being worked primarily for graphite. It pulverized and was dried with less difficulty than the Pennsylvania anthracite.

Every Liberty Bond you buy is a safe financial investment in the future happiness and self-respect of your children. Buy as many as you can and let them inherit as good a country as you did.

Bondholders, don't shout until you are out of the war woods. The danger is still here. Buy bonds until the war is over.

The Boiler Inspector's Work

BY M. T. GLENN

There are many occupations of which the general public knows practically nothing and of the details of which men in kindred pursuits have only a vague idea. One such is that of the boiler inspector. While boiler inspection has been practiced in this country for more than a half century and in Europe for a still longer period, very few, even among the steam-engineering profession, know much about the boiler inspector; how he works, what tools he uses, what he looks for in order to determine whether a boiler is safe or otherwise.

NATURALLY, a boiler inspector is supposed to inspect boilers and, in a vague sort of way, he is expected to be able to predict when a boiler is going to blow up. This latter supposition is not exactly correct, for sometimes an old vessel will display the perversity of inanimate objects and refuse to explode even though it is continued in service long after the inspector "condemns" it and the insurance is cancelled. That the inspector does give timely warning of the impending danger is attested by the fact that comparatively few boilers explode notwithstanding the increasing number in service. Not all boilers are insured or inspected, and it is among those not inspected that a large percentage of the explosions occur.

How the Inspector Goes About His Duties

When a boiler user signs an application for insurance, the insurance company notifies one of its inspectors, and it is his duty to examine the boiler or boilers in question and report upon the construction and condition, stating the safe working pressure. The inspector notifies the plant of the date of his expected arrival early enough to permit preparation for the inspection. He finds his way to the plant (which frequently is a difficult task), proceeds to the boiler room to see if everything is in readiness for him, then inquires where he can change his clothes and is often shown into the engine room, where a greasy chair or workbench serves for a clothes rack. Here he disrobes and, since safety is second nature to him, takes care to leave no money or other valuables in his clothes (in at least one instance an inspector's clothes disappeared during his absence and he had to return to his headquarters in his overalls). He dons an inner suit of light-weight material which is highly absorbent and readily laundered, a pair of socks and rough shoes; then a special oversuit that has boot straps to prevent the legs "riding" up and interfering when he is backing out of a manhole, and an attached hood to keep the hair and back of neck free from soot and ashes. A pair of gauntlet gloves completes the uniform, and he is an object to attract attention whenever he ventures out on the street in this attire, as he sometimes does in order to go from one plant to another near-by.

For an internal inspection the following outfit is required: A small cross-peen hammer, a test pump and gage, and a light. The best type of light to use for this work is a subject of much controversy, and it might be well to digress a few moments and look into the merits and demerits of some of them. Some inspectors prefer the old-style "tallow dip"; others use the candle, but with a special holder which feeds by a spring in the handle so that the light remains about twelve inches from the hand and can thus be introduced into out-of-the-way places. There is a serious objection to the candle aside from the fact that it is becoming more and more difficult to obtain and does not give a very brilliant light, it sometimes melts very quickly in an extremely hot boiler and leaves one in the dark just at a time when he needs a light badly to see how to get out as rapidly as possible. Another type of light that is still used by some who have inspected boilers for many years is a home-made kerosene torch consisting of a piece of gas pipe capped at one end and stuffed with waste at the other. Kerosene oil is obtainable at practically every boiler room, and this "flambeau" has the advantage just mentioned in connection with the special candle holder—it can be poked into narrow crannies, but it is "smelly" and shines in the inspector's eyes as well as on the object at which he wishes to look. Most inspectors prefer either the flash light or the miner's acetylene lamp. They both throw a good light in the desired direction without any back glare. The former is rather expensive to use, and batteries are less easily obtained in small towns than is carbide for the miner's lamp; but it does not have to be cleaned and filled every time it is used, as is the case with the gas light.

Other Things Needed for a First Inspection

But to return to the inspector's outfit, if it is a "first inspection," he will require, in addition to the articles mentioned, a rule, a thickness gage and a pad and pencil, there being no less than 75 items to be filled in on the data sheet for an ordinary horizontal-tubular boiler. It is a matter of habit with an inspector which portion of the boiler he examines first and what sequence he follows, hence the following method or order is given only as an illustration without being set up as an example of the best procedure. Let us assume that he first crawls through the fire-door onto the grates and looks for such defects as burned or blistered plates, cracks or leaks. In the case of a water-tube boiler he strikes the tubes to ascertain if any are getting dangerously thin, notes the condition of walls, baffles, etc., to be sure that no great amount of cold air enters except through the burning fuel and that the gases are directed along the path the designer intended them to take. He then enters the rear clean-out door, gives the same attention to the fire surfaces and setting as at the front end, then enters the boiler by the upper manhole and examines the shell, heads, tubes and braces for such conditions as scale, traces of oil, corrosion in its various forms and any other defects, cracks, missing rivet heads, broken braces and the like. Before leaving this part of the boiler, he examines the feed pipe to see that the opening in its end is clear and that it does not discharge near a seam, plate or tube, and also inspects the other openings to outer attachments. When he enters the lower manhole, he looks for sediment or scale, oil and corrosion, also for indications of burned or cracked plates, which are sometimes seen better from the inside on account of the soot on the fire surfaces, sees that braces are not slack and that the blowoff opening is clear. If there are water tubes, the caps of some of them at least should be removed so that he may obtain an idea of the condition of the whole.

Finishing the boiler proper, he turns his attention to the attachments. The steam gage is taken down and tested; if found incorrect, it is adjusted if possible or a new one ordered. Before the gage is replaced, he blows through the small pipe and connecting valve to be sure that they are unobstructed. The safety valve can be examined only superficially at best when there is no pressure on the boiler, but the inspector endeavors to see the spring, if it is a pop valve, to assure himself that it has not been compressed too closely and that the valve should perform its function. Fortunately, a pop valve seldom gets out of order, and the best way to "fix" a defective one is with a new one and thus be on the side of safety.

The inspector calculates the safe working pressure, taking into consideration age and condition, which enter largely when a boiler has been in operation for considerable time unless the conditions are practically ideal. Mailing in his report and data with a recommendation completes the first inspection.

THE PROPER WAY TO PREPARE A BOILER FOR INSPECTION

In making ready for inspection the fire is first drawn and the pressure permitted to fall to 15 lb. or less, while the ashes and clinkers are removed from the grates and bridge-wall and the soot and ashes from the combustion chamber. When the setting is sufficiently cool to preclude the possibility of damaging the empty boiler, and after the tubes have been blown and fire surfaces swept, the blowoff valve is opened wide and all the water is blown out. Next in order comes the removal of the manhole plates; the top one should be taken off first if the boiler is of the water-tube type, and the blowoff valve should not be closed until this plate is off, unless the boiler is vented by some other means to prevent a vacuum being formed. In opening a horizontal-tubular boiler, the following method should be followed to avoid scalding the one who removes the top manhole plate: Open the lower manhole, close the flue doors and open the damper. The top manhole may now be removed with impunity as the stack draft will draw the steam downward as soon as the joint is broken. Finally, the rear clean-out door and fire-doors are closed, the ashpit doors opened and the boiler left to cool. It will be noticed that with this arrangement the stack draft draws a current of air through the top manhole and then cools much of the water surfaces on its way to the stack via the lower manhole, while another air current enters the ashpit doors and cools the setting and fire surfaces of the boiler. As there is no way to induce this air current except by the aid of the stack draft, it is necessary that the large doors in front be kept closed. Since there is no connection between the water surfaces and the draft in the case of the water-tube type of boiler, it requires more time to cool, but the same method applies regarding the air cooling of the setting and fire surfaces.

Referring to the attention attracted by a boiler inspector while in his suit, the writer was once mistaken for a highwayman, although he did not know it at the time and only learned of it through conversation with a relative of the other party. After inspecting several boilers, he received a message from the office of the mill to come up and answer a long-distance telephone call. He went to the office and, entering through the back door, found himself in a reserved enclosure where the only person in the place was making out the payroll, having, spread out on his desk, several hundred dollars in currency. It was not till some months later that the inspector was told that the cashier confessed that the unexpected appearance of the boiler inspector nearly caused him to have an attack of heart failure, as he mistook him for a robber and was resigned to his fate.

THE INSPECTOR FINDS HIMSELF IN AN EMBARRASSING POSITION

The writer was once mistaken for an inmate of an institution known as the State Hospital for the Insane, although this time he was not dressed in the suit described, but was clothed in his street garb and right mind. Only a fortunate chance prevented his having to spend the night in a ward. After calling the gentleman in charge of the buildings and equipment by telephone and making arrangements to inspect a couple of the boilers, the inspector walked into the grounds through the only gate available, spoke to the gateman and asked where Mr. Blank could be found. Following directions, he found that gentleman and was intrusted with a key to a spare room in which to change his clothes and was told, "Just leave the key with the gateman, I will probably be gone for the day." After finishing his work and changing to his street clothes, the inspector started for home and was a little disturbed to note from a distance that the gateman had been changed since he entered. As he approached the gate, the attendant walked out from his shady bench and intercepted him. He proffered the key and told the man that Mr. Blank had requested him to leave it with the gateman when he left. That worthy had had plenty of experience with the wiles of inmates and their cunning attempts to escape, so without appearing to think it at all strange he accepted the key and promised to see that Mr. Blank got it when he came in the morning, but without in the least relaxing his vigilance or letting the inspector get between him and the open gate. The inspector, in his turn, was careful to make no false move which might lead the gateman to think he belonged inside, hence when the gateman suggested that he go over and have a seat in the shade and take a drink (water—this happened in a "bone-dry" state), he accepted with as good grace as possible and even accepted the proffered afternoon paper, although he used it more to hide his growing uneasiness while forming schemes for outwitting the man near-by and affecting his "get-away" than for reading. Fortunately, a diversion occurred which he guessed might give him time to think more clearly. A medical student serving as an interne at night came in and stopped to pass the time of day with the gateman. Seeing the suspect sitting near-by, he said, "Good evening." The inspector returned the greeting but without much spirit, and when the gateman asked the student if he knew "this man", the inspector thought, "Why, he wouldn't know me from Adam," but was agreeably surprised when the student replied, "Yes, I know him. He is the boiler inspector. I met him and Mr. Blank along the boiler-room walk several days ago." Thus the situation was suddenly relieved for both the inspector and the gateman, who hastily apologized.

The following is an illustration of how little some men know about boilers. An insurance company sent a telegram instructing their inspector in the district to investigate damage to a boiler at an oil mill in a small town, appending the words, "See Mr. Light." On arriving at the oil mill, the inspector accordingly asked for the gentlemen named and was invited into the back office for a confidential talk in which he was told that the mill, which was owned by the speaker, had been leased to a corporation by which he was employed as manager. He had retained his insurance policy on the boilers, and now that one of them was leaking badly around the tubes at the rear end, he feared that the engineer had neglected his business and that the water had been allowed to get low. Mr. Light asked the inspector to examine the boiler and report to him, saying nothing to the other employees around the plant. Upon investigating the interior of the offending vessel, the inspector found scale caked between the tubes several feet from the rear, making a solid mass all the way back to the head, thus preventing water from circulating around the tubes and cooling them and the head. When he reported to Mr. Light that the water had not been allowed to get low and that scale accumulating between the tubes had caused the trouble and must be removed before the boiler was fired any more, that gentleman thanked him and said, "I'm mighty glad to know that it was not neglect on the part of the engineering force. We will have the scale removed."

Why Coils Sometimes Fail To Heat

When pipe coils are used for heating, in conjunction with radiators, it is sometimes noticed that circulation through the coils is not good, especially if they are long and made of small pipe connected up with return bends instead of headers. The reason is the greater resistance of the coil, since the steam must traverse a greater distance. Sometimes a coil will heat at both ends but not all over. This is because steam enters from the return piping as well as from the supply and the air is trapped between the two. The location of the air vent becomes an important matter in such cases.

Waterproofing Porous Material

Brick, stone or cement walls may be rendered waterproof by one or more applications of gasoline in which 5 to 10 per cent. of paraffin wax has been dissolved or cut. The fluid may be applied with a brush or spray pump. It is colorless unless an excessive amount of wax has been used, in which case it will leave a gray color or coating, but coloring matter such as lampblack may be added. The joints of a brick wall may be penciled, then the whole wall gone over with uncolored fluid. The surface should be as dry as possible when the waterproofing is applied, to allow it to penetrate, since the gasoline simply acts as the vehicle to carry the wax into the pores of the material to seal them up. This means of sealing the small pores is also beneficial in reducing air leaks from concrete fan ducts, etc. The disintegration of porous material when exposed to moisture and then to freezing temperature is caused by the irresistible expansive force exerted by the entrapped water in freezing. This of course applies to cement walks and roofing as well, so that waterproofing is beneficial in many ways.

Turner Baffle-Wall Construction

The shapes of the vertical passes in water-tube boilers have been determined largely by the fact that loose tile placed against flame plates were used for the baffle walls. Effort to build an inclined wall to give the theoretically perfect pass resulted in the dislodgment of the tile under the vibration of the tubes, due to the tube cleaners or to the release of the steam bubbles and from the action of soot blower, etc.

Replacing loose tile is a difficult matter, as tile of the original size cannot be used without spreading the tubes temporarily to get the tile in place, and the alternative is to use smaller tile which results in wide-open joints through which the hot gases short-circuit.

With the development of the Turner baffle wall, by the Engineer Co., 17 Battery Place, New York City, a construction is provided that eliminates these objectionable features. This wall is built by introducing in the diagonal alleys between the tubes a molded, corrugated tile, dovetailed at the ends. The pockets thus formed by the tubes and the adjacent rows of tile are filled with a plastic material which fills the space no matter

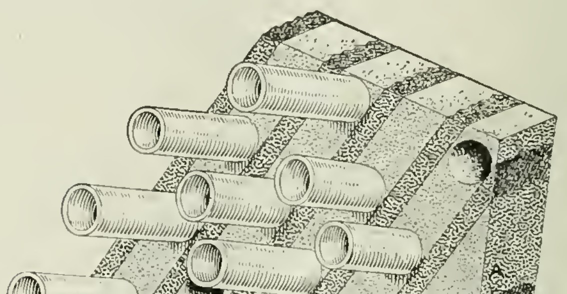

FIG. 1. DETAILS OF BAFFLE-WALL CONSTRUCTION

how irregular. This plastic material does not grip the tubes as it shrinks in hardening and leaves a small annular space around them. A tube can be withdrawn when cold and replaced by another. The filling cannot be displaced, however, as it bonds with the corrugations *A* in the tile, and the latter dovetail at each end with each other as at *B*, Fig. 1.

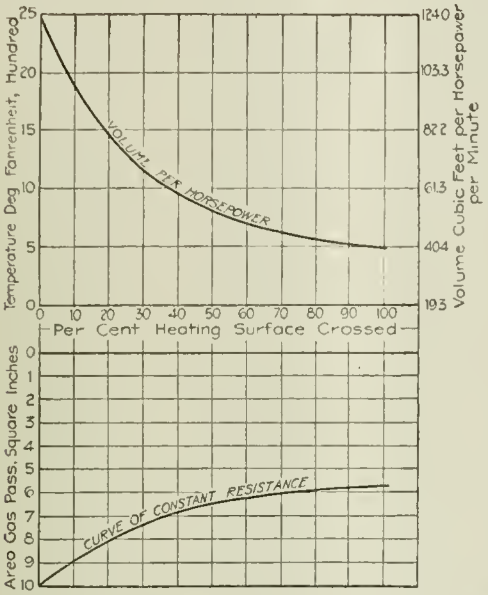

FIG. 2. TOP CURVE SHOWS RELATION OF GAS TEMPERATURE AND VOLUME; LOWER CURVE, AREA OF GAS PASS; EACH FOR PERCENTAGE OF HEATING SURFACE CROSSED

It is therefore possible to build a practically gas-tight wall at any desired slope through which tubes can be withdrawn and replaced without damage to the wall. No flame plates are necessary.

It has been found an advantage in boiler design to give the gases of combustion as near a uniform velocity through the passes as possible. A study of the curve showing the decrease in volume of these gases due to the cooling effect of the surfaces over which they pass (Fig. 2) shows that with 40 per cent. of the heating surface in the first pass, the area of its outlet should be about 60 per cent. of the area at the bottom. As the cooling effect of the drum and the superheater are comparatively small, the area at the top of the second pass should be somewhat less than that at the top of th first pass and the second pass should also taper.

The third pass shows little cooling effect, and its shape is not so material, so long as ample space is provided for the exit of the gases.

The elevation of the boiler shown in Fig. 3 illustrates the application of these principles. The bridge-wall is moved back to enlarge the furnace chamber and to keep down the furnace temperature. By the location of the bridge-wall the opening of the first pass was established. The Turner wall starts from the bridge-wall and slopes forward at such an angle as to make the top area 60 per cent. of the bottom, the heating surface exposed in first pass being about 40 per cent. of the total.

The rear wall is carried down at right angles to the tubes, it being a matter of judgment as to its slope and how far down to extend it. Some engineers claim it is an advantage to contract the lower end of the second pass so as to increase the velocity of the gases at this point and shoot them well down over the lower rows of tubes and toward the rear end of the boiler. The expansion of the gases on their release also helps to this end, and the reduction in velocity due to the change from passage across the tubes to passage along the tubes, as well as the mushrooming into the space back of the bridge-wall, tends to drop into that space any cinders or soot that would otherwise be carried up the stack.

The advantage over the alternative use of a short section of horizontal baffle on the lower row of tubes running forward from the top of the bridge-wall to the bottom of the ordinary baffle wall, Fig. 3, is evident. First, a larger tube surface is exposed in the first pass to the radiant heat of the fire and to the gases when hottest, tending to increase the capacity and at the same time lower the furnace temperature, since the heat goes into the water instead of the setting. Second, a flat surface and not an elbow with a joint impossible to keep tight with the inevitable expansion and contraction of the horizontal baffle is presented to the flames. Third, the difficulty of renewing the lower tubes, which are most frequently burned out, is lessened as they carry no horizontal baffles. Fourth, there is no dead angle at the bottom of the second pass where the vertical and the horizontal baffles join. Fifth, there is no leakage as there would be through the horizontal and transverse joints of the horizontal baffles.

Another application of the sloping baffle wall is the downward extension of the rear baffle to lessen cinder carrying by reason of the change in the velocity and by the momentum of the cinders shooting them clear of the gases when the latter turn upward. This action does not take place readily when the turn is made among the tubes, as the cinders hit the tubes, rebound, are caught up and carried away by the gases.

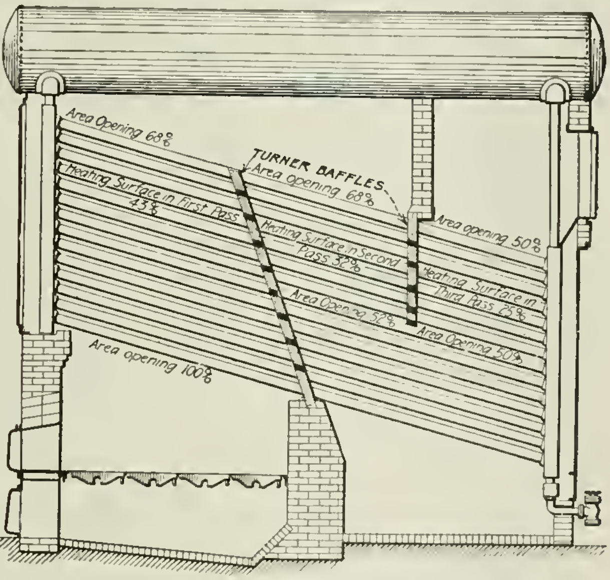

FIG. 3. CONSTRUCTION OF BAFFLE WALLS FOR MAINTAINING UNIFORM GAS VELOCITIES

As a nation we have drafted men to fight for us. That means we have chosen them to suffer hardship and to sacrifice life, if need be, to protect us and our interests. This places upon each one of us an equal obligation to suffer whatever hardships are necessary to give them all the equipment they need for success.

FINANCING THE SECOND YEAR OF THE WAR

Share of Yearly Incomes Contributable in Taxes and Bond Purchases

Distribution of incomes of $3,000 and over based on income tax returns for 1916; below $3,000 on carefully made estimates

Reported non-taxable incomes not apportioned in reports—50% estimated contributable				. . . . .	2,000,000,000	1,000,000,000
Family Groups and individuals—their estimated total incomes and ability to contribute				27,304,199	$38.250,000,000	$7,250,000,000
Corporations and other business enterprises—their estimated total incomes and ability to contribute after dividend distributions				. . . . .	11,750,000,000	2,750,000,000
Total estimated National Income and amount realizable therefrom				. . . . .	$50,000,000,000	$10,000,000,000
Banks—the share of the burden which they probably must carry. This is not the estimated peak load, but a conservative estimate of the average minimum burden						3,500,000,000
Estimated receipts from direct taxation and bond sales						$13,500,000,000
Estimated receipts from indirect taxes, such as customs, excise taxes, stamp taxes, including sundry receipts						1,500,000,000
Cost of Second Year of the War, estimated						$15,000,000,000

*This group is largely composed of individuals.

HOW TO USE THE TABLE: Find your income in Column I. Multiply this by the "percentage contributable,"—Column III. The result is the total amount which you should contribute during a year. Deduct the amount which you pay in taxes—the remainder is the amount of Liberty Bonds which you should buy from income during a year.

Illustration:	$5,000 income.	Less tax, say $80		$10,000 income.	Less tax, say $675
	$5,000 x 22.4% = $1,120	Bonds to be bought $1,040		$10,000 x 40% = $4,000	Bonds to be bought $3,325

Editorials

What Is My Share of the Cost of the War?

HIS or her share in the cost of carrying on this great conflict to make the world a decent place to live in is one of the questions that should be foremost in the minds of every man and woman in this country today. The Bankers Trust Company, of New York City, recently issued a pamphlet, "What is my Share of the Cost of the War," in which the problem of financing the second year of the war is discussed. The analysis set forth in this pamphlet brings the problem home so vividly that it should make every American do more than think; it should make him act. The table on page 624 of this issue is taken from this pamphlet and gives a very comprehensive presentation of the task.

According to the pamphlet, "During the first year of the war the expenditures of the Government have amounted to over nine and a half billion dollars, or more than fourteen times the average expenditures of the seven years previous to the war. The advances which we made to our Allies for the purchase of materials and supplies have accounted for nearly one-half of our total expenditures.

"The expenses for the next twelve months will probably be considerably larger. Congress voted appropriations for the current fiscal year ending June 13, next, of eighteen and three-quarter billion dollars, but the Government has not found it possible to expend this amount of money, and we doubt if such a large amount can be expended in the coming twelve months. We believe that it is safe to estimate the total expenditures for the next twelve months at about fifteen billion dollars; therefore, to raise this amount is the task we are facing."

Regarding the use of the table the pamphlet points out several things that it is important to keep in mind. One of these is: "The calculations, except for incomes below eight hundred and fifty dollars, are based on family incomes. This seems fair because most of us live in families and perforce think and act in terms of family income and outgo. It goes without saying, however, that an individual without family responsibilities can contribute proportionately more from a given income than the head of a family can contribute or than a given family group having the same income can contribute." In other words, one is not only to contribute the part set forth in the table, but all that it is possible for him to contribute.

The authors call attention to the fact that "in no better way can there be brought home to one the magnitude of the burden of this war and what it means than to consider conscientiously what constitutes ones fair share of the burden. It is no use to blink at the facts of the case. We may as well face them now and, if we have not already done so, prepare to adjust our affairs so that we can take up the burden. Not for this year alone, but perhaps for next year and then for other years to follow.

"It is obvious that business and methods of living heretofore customary cannot go on as usual. In the last analysis what the Government needs is not money but goods and service. Therefore, to the extent that each one of us curtails his wants and thus releases industrial operatives and goods for war work, he is to that degree giving the greatest assistance to the Government. In this way also individual expenditure is automatically decreased with a corresponding increase available to the Government. It behooves us, therefore, to take stock of our resources and to determine thoughtfully and methodically what is the greatest amount of bonds for which we can arrange to subscribe."

Using the Nation's Lignite Supply

IF YOU will look at the coal map of the United States you will see that the Southwest and the Northwest, particularly the Dakotas, North Dakota especially, contain considerable deposits of lignites. The North Dakota natural lignite has about the following average composition: Moisture, forty per cent.; volatile matter, twenty-five per cent.; fixed carbon, twenty-eight per cent.; ash, seven per cent., the heating value being about 6300 B.t.u. per pound. These sections of the country are remote from the coal fields of the East, and they are distant from the Illinois and Indiana coal fields. When these sections of the country use coal either from the Kentucky, Tennessee or West Virginia fields, or the Pennsylvania field, and from the coal fields of the Middle West, the coal must be transported long distances by rail and the lakes and at considerable cost, which becomes more than a monetary loss during a time of rail congestion. National economics, therefore, seems to dictate that the industries adjacent to the lignite fields should learn how to burn this fuel. Lignite in a natural state cannot be transported even short distances from the mines for the reason that the moisture evaporates, causing the lignite to break up into small chunks and flakes and, if subjected to much jarring, it disintegrates into powder, all of which makes the fuel inconvenient to handle.

While commendable progress has been made in the use of lignites, they are not used on a large scale, even by the industries adjacent to the lignite fields. Experience has shown, however, that lignites can be burned under boiler furnaces without insurmountable difficulty. An electric company in Colorado, for example, has been successful in burning natural lignites on an underfeed stoker, the stoker enabling the boiler to develop ratings up to 300 per cent. of normal, and to be able to put the boiler on the line under full boiler pressure from a fire at dead bank in five to seven minutes. This is a boiler installation of the usual kind; that is, the boiler is not overstokered. Altogether, experience in this Colorado station has shown that even with the ordinary type of underfeed stoker in a boiler setting not especially designed for lignite fuels, great flexibility in boiler output is possible. During the fuel crisis of last winter, the people of North Dakota successfully burned lignite in house-heating boilers and stoves. The experience in Colorado and North Dakota, together with that in Texas, where lignites abound, shows that the lignites may be burned under boilers used for power purposes.

It is likely that experience will dictate that the natural lignites be carbonized; that is, that the moisture particularly be driven off before the fuel is transported long distances. The carbonized lignite presents no difficulty in burning under power boilers.

Elsewhere in this issue Henry Kreisinger, engineer of the Bureau of Mines, and well known for his work on combustion in boilers, has a most interesting article on the combustion of North Dakota lignite, with suggestions for the design of furnaces to burn this fuel. It is interesting to note that combustion is limited to the first three or four inches of the fuel bed of a lignite fire and that the CO_2 is rapidly and completely reduced to CO within the first four of the fuel bed. This, of course, makes necessary the introduction of oxygen or air above and against the fuel bed in order that the CO may be burned to CO_2. It is interesting to note, also, that the reduction of the CO_2 to CO near the surface of the fuel bed is such a heat-absorbing process that the surface of the fuel bed under ordinary conditions is a dull red. With a natural lignite, the absorption of heat by the moisture is a factor in causing combustion to be slow at the surface of a lignite fuel bed.

It is of particular interest to note that the author is of the opinion that an ordinary horizontal grate is unsuited to lignite and that a step grate should be used. The step grate is best adapted for the reason that the ash may find its way down the grate and will not plug the air spaces which, in a separate grate, may be made very large, as they must necessarily be to burn the lignite with success. The step grate also avoids dropping the ash and combustible into the ashpit where, with an ordinary horizontal grate, the ashpit may, when burning lignite, contain more fire than the grate itself.

It is Mr. Kreisinger's opinion that a chain grate, if inclined about fifteen degrees toward the refuse end, and set in a furnace having a long combustion arch extending from the rear far forward in order to drive the flame down upon the incoming coal which, of course, is high in moisture, will successfully burn natural lignite. Directing the flame forward is intended to drive off the moisture from the incoming green coal. We are sure that Mr. Kreisinger's article will add appreciably to the literature on this subject and that the results of his investigations will prove of material value to those engaged in designing furnaces for successfully burning the lignite fuels.

It is up to the builders of stokers and furnaces to take advantage of the experiments of the Bureau of Mines and supplement them with research of their own to the end that stokers and furnaces particularly adapted to lignites may be available to industries in and near the vast lignite fields.

We should not be unmindful of the apparent possibilities of burning lignite in powdered form, particularly so in view of the low fusing temperature of the ash, namely, two thousand degrees Fahrenheit. Just what success have the powdered-fuel exponents had burning lignite in pulverized form?

Coal-Saving Nostrums

STILL again we are forced to call attention to the numerous nostrums which are being urged upon the public as fuel savers. There are usually a few sporadic cases in evidence, but the present exceptional conditions with regard to fuel have engendered a veritable epidemic of them. "Kologen" will save, according to the advertisement, from twenty-five to forty per cent. of your coal bills, and you can get enough for fifty cents to treat a ton of coal. A patriot by the name of Schoen will give you a formula for effecting the same result. The formula is water, salt, and "one common chemical," the name of which he sells ordinarily for one dollar. But as every ton of coal saved now helps win the war, he considers it a patriotic duty to spread these instructions as widely as possible; so during the present emergency a silver quarter, "to cover cost," gets it by return mail. It does not seem to have occurred to the aforenamed patriot that it would not take so much space in the advertisement to name the ingredient as to call it "a common chemical," and if it were any good any paper would be glad to print it for its news value.

Meyers' patent compound for saving coal is another. We have analyzed and exposed many of these nostrums. There is no substance which, sprinkled upon coal, can save one-third, one-quarter, one-tenth, or any appreciable proportion of it, except through the psychological process of leading the fireman to expect an improvement and unconsciously to bring it about; and there is no need of paying twenty-five or fifty cents for a canful of cheap chemicals in order to do this.

Will the Coal Shortage Continue?

WASHINGTON cannot conceal the fact that the Fuel Administration and the Railroad Administration are at loggerheads. As a result there is an alarming shortage of bituminous output because of car shortage. Goodness knows, we went through enough distress last winter, some of it unavoidable, much of it avoidable. Are we to face it again? If so, is it to be because some officials want to make a showing on cost sheets? If these men do not want to appear as selfish children, let them cease to be childish. The public is sick of needless messes. It wants coal, it needs it; miners want to work steadily, car builders are not holding back. Let the Railroad Administration drop the bludgeon it holds over Mr. Garfield.

During the period of agitation on the daylight-saving law, which went into effect April 1, many objections were raised against it. However, the reports coming from different quarters would indicate that the evening peak of the central stations is being considerably relieved without adding anything to the morning peak, a coal saving is obtained, and furthermore, what was not expected, it has proved to be a public safety and defense feature—so much so that the executive committee of the United States Chamber of Commerce at a recent meeting was unanimous in its agreement that the measure should be made a permanent one to operate through the year.

Correspondence

Something To Be Proud Of

I am sure that *Power* readers will be interested in some figures on running an ordinary 500-hp. plant during the unusual year of 1917. This is an old plant, started in 1850 as a mill, now furnishing power to eleven tenants, using individually from 3 to 109 hp., and scattered over a property 400 ft. square. Until March we were running both shaft and electric drives, but at that time we cut off all the shaft drive and are now all on electric transmission. During the last year we delivered an average of 365 hp. to the tenants, at a cost of $23,750, or $65 per hp. These figures are so unusually high for those which anyone is willing to publish that readers would be interested in some of the incidental things that go to make up this result.

All the employees of the plant have had their wages increased about 25 per cent. this past year; our payroll was $80 a week for regular running and $9 a week for overtime on maintenance and repairs, making a total of $89 a week, or $4632 for the year. Our coal bill was for 2564 tons at $6.10, or $15,640; our bills for supplies and repairs were $1688. Some of the items of this amount are as follows: Boiler repairs, $451; oils and grease, $135; boiler compound, $65; building repairs, $32; water, $257; stoker and furnace repairs, $138; engine repairs, $16; packing, $37; electrical supplies and repairs, $144; pipe, valves and fittings, $109. Taxes and insurance amounted to $900.

We are equipped with water-tube boilers and overfeed stokers, and slide-valve automatic engines, and furnish direct current at 115 volts for both power and lighting.

We burn bituminous slack, which during 1916 cost us $3.10 a ton on the boiler-room floor. During 1917 this coal or other coal bought to fill our requirements cost $6.10 per ton on the boiler-room floor. In addition to this condition, the water evaporation fell from 10 to 8 lb. on account of poor coal, poorly prepared coal or coals of qualities strange to us, which puzzled us to find the best method of firing. It was also necessary for six months to put an extra man in the boiler room on account of these conditions.

Our engines are using 40 lb. of steam per indicated horsepower-power, and the efficiency from the indicated horsepower to the tenant's recording wattmeters is 75 per cent. We delivered 317 hp. to these wattmeters, which was 423 i.hp. at engines. On a steam consumption of 40 lb. this equaled 564 hp. at the boilers at 30 lb. per boiler hp. In addition to this we delivered 48 boiler hp. of live steam, which we recorded with condensation meters. This 612 boiler hp. did not include steam used in feed pumps and stoker engines or condensation in mains. Our boilers were run at about rating, on an average.

Notwithstanding the high costs of power, caused principally by inefficient engines, along with some 35-year old equipment which I have not as yet been able to get rid of, and with high-priced coal, one of our large central stations, which has 30,000 kw. turbines, has been unable to make an interesting proposition to us, practically failing on the one point of heating the buildings. Exhaust steam for heating has saved us where our engines would have thrown us down.

Our figures for building maintenance were: Repair and supply bills, $1382; payroll, $4196; coal, $3910; taxes and insurance, $1500; Total, $10,988.

We have 180,000 sq. ft. of rentable floor space, which makes the maintenance costs less than 7c. per sq.ft. In proportioning the boiler-room costs, including coal, we proportion 80 per cent. to power and 20 per cent. to buildings.

Regardless of these unvarnished figures, which are truly "something awful," we are proud of what we accomplished last year. By "we" I mean my men, who have backed me up so well, our manager, who has done the same, and myself—coöperation which is hard to beat. Surrounded by unfavorable conditions, we have made a determined effort to make the most out of them, and feel that we have done our "bit," as over three-fourths of our power was used for strictly Government essentials, and the balance was utilized for various good purposes. ARTHUR SUMMERS.

Philadelphia, Penn.

Synchronoscope Operated Sluggishly

Synchronizing indicators are intended to be connected to the circuit only during the period that they are actually in use. If these instruments are left connected to the circuit permanently, there is danger that they will be overheated and injured. In a certain instance a synchronizer had for some time evinced a tendency to act sluggishly. The sluggish action of the instrument apparently did not suggest to the operator that its indications might not be dependable, since it was not until two machines had been connected together while out of phase that the operator awakened to the possibility of an investigation being in order. Testing failed to reveal any open-circuits or other external irregularities, and as the synchronizing lamps continued to be normal in their indications, it appeared that the trouble must be located within the synchronizer itself.

The instrument was removed from the switchboard and partly disassembled, when it was discovered that, owing to overheating, insulating compound had run out of the windings and clogged the air gap between the rotating member and the polepieces, so that the former was practically prevented from turning. However, the winding appeared not to have been injured, and after cleaning the air gap, a trial of the instrument proved its indications to be normal. The heating was found to be caused by the operator leaving the instrument connected to the circuit continuously.

Brooklyn, N. Y. E. C. PARHAM.

A Peculiar Wiring Trouble

Recently, a friend of mine took charge of a power plant that was in a somewhat neglected condition. Among other troubles one of the fuses on one side of a lamp circuit kept blowing frequently. Finally, the circuit was fused with copper wire, and this solved the problem as far as that particular circuit was concerned. Soon after the circuit lighting the boiler room started the same trouble; the fuse blew on one side of it. This circuit was also fused with solid copper, which ended difficulties as far as fuse blowing was concerned.

A signal bell in the engine room had been giving considerable trouble from the contact point on the vibrator burning so badly as to render it inoperative a number of times. A short time after the boiler-room circuit had been fused with copper wire, the same trouble happened to the bell again, and it was also found that the push-buttons were so badly burned as to be useless. New push-buttons were put in, and in a short time the bell and buttons were found to be burned out again.

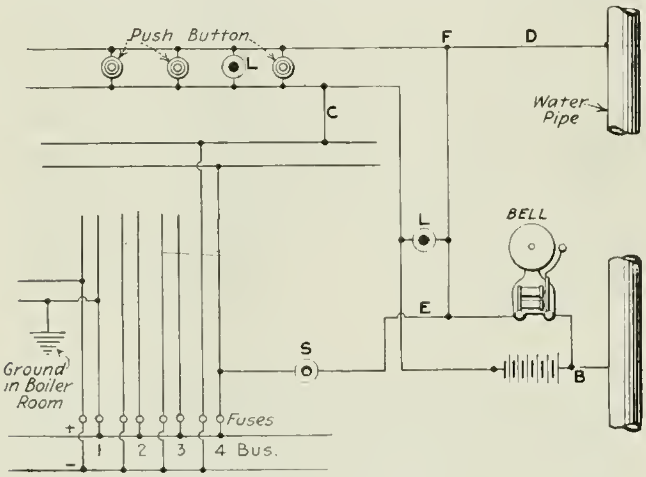

DIAGRAM OF BELL AND LIGHTING CIRCUITS

It is quite evident that the bell wire was in contact with 110-volt lighting circuit at some place. Testing the bell wire failed to locate anything wrong, however. It was therefore decided to arrange a telltale light to indicate whenever the lighting-circuit voltage might be present on the bell. One lamp was connected across the bell circuit close to one of the push-buttons, and another was connected across the bell wire near the bell in the engine room. The sketch illustrates the connections, and *L* and *L* indicate the location of the telltale lamps. The next morning after the lamps were installed they lighted.

To find the circuit on which the trouble originated, the fuses of each circuit were removed and replaced one at a time. When the fuse on the negative side of circuit No. 4 was removed, the light went out. This, by the way, was the side that was fused with copper wire. When the fuse was replaced, the lamps lit again.

When the positive fuse of circuit No. 1 was removed, the lights went out again. This was the boiler-room circuit and did not come anywhere near the bell wire. In tracing out the wires on circuit No. 4 we found that a tap had been taken off one side of the circuit and run between the beams of the ceiling to one side of the bell circuit, indicated at *C*. From this it will be seen that one side of the bell wire was connected to the negative side of a lighting system. Following the bell wire back to the engine room, near the elevator shaft one side of the bell circuit was found connected to a water pipe, as shown at *D*. When this wire was removed, the telltale lights went out.

In the engine room, connected to another water pipe, was found a short wire that had apparently been disconnected from the bell some time before, as the end was hanging near the bell. Another wire was connected to the bell wiring at point *E* and ran along the ceiling through a lamp socket *S* to positive side of circuit No. 4.

Evidently, at some time an attempt had been made to operate the bell on a circuit taken from the lighting system, and to cut down the expense of wire the use of the water pipes had been resorted to. Under the conditions shown, whenever a ground occurred on the positive side of a system, it is plainly evident that there would be full voltage across the bell, as the circuit would be complete from the ground in the boiler room through connection *D* between the point *F* and the water pipe, around to the bell and battery and through *C* to the negative side of the line. This is what burned off the contact point of the bell. After this occurred full lighting-circuit voltage existed across the push-buttons. Closing the push-buttons practically amounted to a short circuit.

The trouble on the boiler-room circuit was due to one of the wires coming loose from the knob on which it had been fastened and swinging down from the ceiling. The plant was provided with a damper regulator, and when the damper was wide open the wire became squeezed between the arm of the regulator and a wooden post. This also explained the intermittent action of the trouble. Unless the damper was wide open, the wire would not be grounded and no trouble would be experienced.

Ash-Handling Machinery

Herbert E. Birch, in his article on "Buying an Ash Handling System," in your issue of Feb. 5, page 186, mentions the liability to explosion with the pipe conveyor system, as referred to in the Apr. 3, 1917, issue of *Power*. In this connection I would like to call attention to the fact that it will be impossible to have an explosion in the tank connected with a steam-jet system, although the writer knows of several explosions that have occurred where the air system was used.

There seems to be in the construction of the article a thinly veiled effort to discredit the steam-jet system, and I am satisfied that if the author of this article had investigated the latter conclusively, he would not consider the prices advertised in your journal as handling a ton of ashes by this system as "salesmen's hot air." It is generally conceded that conveyors of any class are more efficient than man-power pushing a wheelbarrow or other device. As to the cost of systems, I believe that the specific price of $2200 is rather ill-advised for the reason that I am personally familiar with systems costing considerably less and at the same time have known systems including the bin for the reception of ashes that have cost less.

St. Louis, Mo. ROBERT H. MILLER.

The Boston Turbine Accident

In reading the description of the wrecking of the 35,000-kw. turbine at Boston, in the Mar. 19, 1918, issue of *Power*, the facts and evidence as given suggest an apparently clear and logical process of demolition through which the exhaust end of the turbine may have passed.

The first indication of trouble, according to the article, was when the machine was heard to rub and observed to vibrate, and this came in the nature of a shock. Simultaneously the turbine was heavily overloaded. The operators tried to stop the rubbing, but were unable to do so. These facts can be accounted for by the distortion of the 18th diaphragm, probably in the nozzle vanes, due to increased pressure drop between the 18th and 19th stages, allowing the diaphragm disk to rub the inlet side prongs of the blade forks of the 18th wheel, causing heating in these prongs. When a sufficiently high temperature had been reached, with the consequent reduction of the tensile strength of the blade material, these prongs parted and allowed the blades to foul the nozzle vanes of the 19th diaphragm. This fouling would cause the second shock and commotion. The time required for heating the prongs would be the reason for the time which elapsed between the first and second shocks. The 18th wheel blade débris shows that the inlet side prongs were burned blue and fused, and fractured near the root.

The 18th wheel blades fouling the 19th diaphragm nozzle vanes would partly sever these vanes and allow the 19th diaphragm disk to drop down on the hubs of the 18th and 19th wheels and begin to revolve, completely parting the disk from its ring. The 19th wheel blades would be fouled by the 19th diaphragm nozzle vanes, which, in turn, wouuld foul the nozzle vanes of the 20th diaphragm. The disk of the 20th diaphragm would be parted from its ring and begin revolving in a manner similar to the 19th diaphragm disk. When a sufficiently high speed was attained, the diaphragm disk would burst and begin throwing off pieces. One of the diaphragm disks evidently started disrupting first, and in doing so pieces were probably projected against the diaphragm-supporting cone and deflected toward the generator end. The five pieces that went through the building wall near the generator end of the shaft uphold this supposition. The lapse of time between the second shock and the instant pieces began coming through the turbine casing, when the operating crew were seeking cover, would allow the severed diaphragm disks to reach their bursting speeds.

These diaphragm disk pieces in striking the diaphragm-supporting cone would possibly break it up. The probable weakest section for resisting such blows would be through the 18th diaphragm groove—the supporting cone being held to the shape by the 17th diaphragm and the adjacent external flange. The upper factured piece or pieces of the cone would drop down on the wheels, be whirled around, possibly demolish the exhaust end bearing bracket of the turbine, and finally land among the condenser tubes. The other revolving diaphragm disk probably let go after the supporting cone had been destroyed. The diaphragm pieces that were thrown off radially suggest this action.

Nothing is said of the 18th diaphragm in the description of the accident.[1] It would also be of interest to know to which diaphragm disk the five pieces found near the generator end of the shaft belonged.[2] It would appear that the primary cause of the accident was in the 18th diaphragm, and a secondary cause the absence of a protective rubbing surface on the rim of the 18th wheel, although the 18th, 19th and 20th wheels all have the forked blading.

In the comment on the windage test of the last stage wheel of the 25,000-kw. turbine it would appear that the medium in which this test was run was air at atmospheric pressure. Whether the wrecked turbine at Boston was supplied with a vacuum breaker the description does not say, but a vacuum breaker operating in conjunction with the emergency trip throttle valve would be a means of braking a turbine wherein the blade velocities are high, after the generator had been disconnected from its load and before the air pump could be shut down.

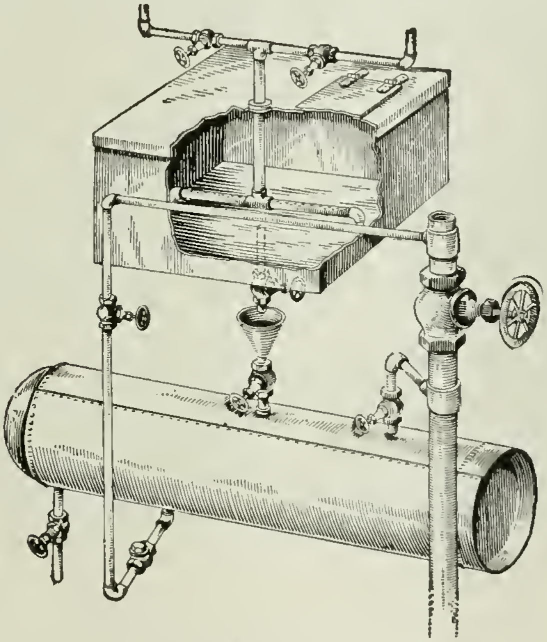
Portland, Ore.

Compound Mixing and Feeding Tank

There are many arrangements of tanks for mixing and feeding boiler compound, but I think I have a better one than any I have seen or read about, therefore I submit it. The illustration will show at a glance its good points. Circulation through the tank is regulated by partly closing the valve in the main-feed line to the boilers. The piping arrangement shown is only intended to convey the general idea and may be modified to suit conditions.



BOILER-COMPOUND FEEDER

B. DAN DE PASS.

Hudson Heights, N. J.

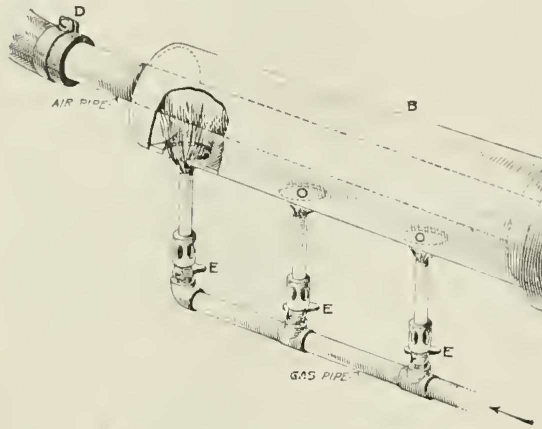
---

[1] "All wheels and diaphragms up to and including the 17th stage are intact." See paragraph under Fig. 4, page 393, "Power," Mar. 19.

[2] See top of second column, page 392 of "Power," Mar. 19: "When this frame broke it is probable that the 19th and 20th diaphragms let down on the shaft. . . The significant fact is that these diaphragms are the only large pieces of metal to completely break up and leave the turbine. It was some of these pieces that went through the roof and terra-cotta temporary end wall of the building."

Drying Out Electric Motors

During a high-water period in the Ohio River one part of our plant was submerged, putting many of the motor-driven machines out of commission. We cleaned the machines as quickly as possible, but drying out the motors proved to be a somewhat difficult proposition. After trying several schemes, the method shown in the illustration was devised and used successfully.



METHOD OF HEATING AIR IN A PIPE

Referring to the figure, *A* is a ½-in. pipe leading from a compressed air receiver. A reducing valve was placed in the pipe line before entering the plug *P*. This valve reduced the air pressure down to about 30 lb. per sq.in., which we found more satisfactory than a higher pressure. *B* is a piece of 3-in. iron pipe with openings *O* to allow the gas flames to heat the air in the pipe *A*. Several gas jets may be used, if necessary to work on more than one motor at a time.

A tee-joint may be placed at *D* for branch pipes leading to different motors. The whole heating apparatus can be placed on the floor, and by using flexible-hose branches, the scheme makes a very convenient arrangement.

We left the motors on the floor and blew the air through them, regulating the gas flame so that the air was kept at a temperature that may be called warm. Flexible nozzles covered with asbestos paper were used, as they were found to be better than solid metallic nozzles for getting into the different parts of the motors easily. G. E. MICHAEL.

Pittsburgh, Penn.

Repair the Liberty Bell

Having become acquainted with the wonderful versatility of the oxyacetylene welding torch, the picture of the Liberty Bell on the cover of *Power*, Mar. 26, suggests, "Why not repair the Liberty Bell and have it ready to ring when the Prussians are beaten and the war comes to an end?" There certainly must be some welder who would undertake the job and who is skillful enough to insure its success. I have welded large gongs and small dinner bells of bronze that resounded just as melodiously as when new, before developing any defect. Welding seems to restore the tone of a bell completely. If the welding is done from the inside of the Liberty Bell, there will be nothing to show that there ever had been a crack.

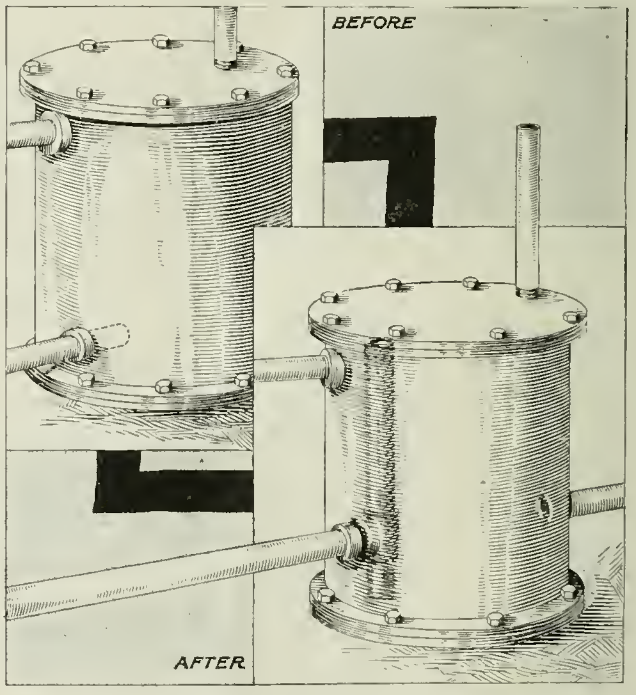
Think of the old Liberty Bell at the conclusion of the war lifting up its voice again, speaking once more for Liberty in a glad peal resounding from one end of the land to the other. Sentiment might, it is true, be aroused against restoring the voice to the bell, but as well refuse to restore the sight, hearing or voice of some cherished one who had become afflicted, when the surgeon offers a cure. There may perhaps be a reason why welding this bell is impossible. At least it ought to be put up to an expert before the glorious old bell is abandoned to perpetual dumbness. M. MEIGS.

Keokuk, Iowa.

Keeping Oil Out of Feed Pump

We were troubled with oil in our boilers following the time the receiving tank got pumped dry. A repetition of the accidental pumping dry was remedied in a satisfactory and inexpensive way, as shown in the illustration.

The original suction pipe extended straight in, while the new arrangement has a tee on the end of the pump suction pipe, and an open-end standpipe extending above the overflow level, so that when the water level reaches the suction level, air is admitted to the pump through the standpipe and the pump gets no more water, leaving a seal of several inches. The oil is disposed of through the overflow by allowing the tank to fill and overflow occasionally, so it goes outside instead of into the boilers. This arrangement is cheaper than float valves, etc., and is sure to work.



INSIDE PIPING KEEPS SURFACE OIL FROM PUMP

Oil City, Penn. T. A. MARSHALL.

An Electrical Phenomenon

On page 594, Apr. 23 issue, the discussion letter "An Electrical Phenomenon" should have been signed, Dr. K. Becker, Perth Amboy, N. J.—Editor.

Inquiries of General Interest

Cleaning Water-Leg of Vertical Boiler—How can the water-leg of a vertical fire-tube boiler be thoroughly cleaned? B. W.

Fasten a chain to the end of a wire, having each of sufficient length to pass around the inside of the boiler from one handhole to the next. Then draw the chain into the water-leg and pull it back and forth while washing out the loose dirt with water from a hose.

Negative Exhaust Lap—In a D slide valve what is negative exhaust lap and what is its effect on operation of an engine? T. J. M.

Negative exhaust lap is the amount by which the exhaust edge of the valve fails to cover the port when the valve is in its central position. The effect of negative exhaust lap is to hasten the opening and delay the closing of the ports to the exhaust.

Breakage of Spring of Shaft Governor—What would result if the spring of a shaft governor should break while in use on a high-speed engine? W. F.

The office of the spring is to oppose the action of the centrifugal force on the governor weight in causing shorter cutoff. With the centrifugal force unrestrained, cutoff would take place at the earliest point, the speed would immediately be reduced, and unless the engine were relieved of the load it would slow down or stop.

Indications of Carrying Water Too Low—What are indications that water has been carried too low in a boiler? E. T.

Low water causes tubes to leak at their ends and burning of heating surfaces that have been uncovered by water. Examination of the interior of the boiler will show red coloration of the material at the point where the water has been too low and scale will be cracked off down to the level at which the water was carried.

Parabolic Governor—What is a parabolic governor? F. J. M.

A parabolic governor is one in which the governor balls are constrained to move in the path of a parabola whose principal axis is the vertical axis of rotation. The height of an equivalent pendulum suspension of the balls is constant for all positions, the governor is in equilibrium at but one speed and is said to be isochronous. Such a governor cannot be used successfully on an engine without checking its action with a spring or dashpot, for the slightest increase in speed above the normal causes the balls to rise to their highest position with sudden decrease of speed, alternating with promptly falling and increase of speed.

Movement of Main Bearing on Bedstone—How can movement of the low pressure side main bearing of a cross compound engine on the bedstone be remedied? W. P. S.

If the nuts on the foundation bolts cannot be set down hard enough to hold the stand from slipping, it may be that the bolts are not threaded long enough and washers are required, or that the anchorages are not holding. If the bolts are smaller than the bolt holes in the bedstone, filling the cavities with a thin grouting of neat cement may improve the anchoring or at least hold the bolts steadier. If the anchorages are secure, then with the nuts of all foundation bolts set down hard there should be no movement over the bedstone if the engine is in good alignment.

Testing Accuracy of Vacuum Gage—How is the accuracy of a vacuum gage tested? R. A.

A vacuum gage is generally provided with a dial and pointer for indicating inches of mercury pressure below the pressure of the atmosphere. A gage of this kind usually is tested by connecting it to one end of a U-shaped glass tube of which both legs are about 30 in. long and filled about half their length with mercury. For calibrating the gage one end of the U-tube and the gage are connected to the receiver of an air pump or an ejector operated by steam or water. If the gage is correct, its readings will agree with the number of inches difference in level of the mercury in the legs of the U-tube for different degrees of exhaustion. If a condensing engine is operating when the calibration is to be made, the gage and U-tube may be connected to the condenser and a comparison of the readings will show the errors of the gage for the condenser pressures that are present.

Pump-Piston Speeds and Relative Capacities—What is considered good practical piston speed for reciprocating pumps of various lengths of stroke? Having two pumps of the same diameter and different lengths of stroke, would the pump of longer stroke be considered to have greater capacity? B. F. K.

Good working piston speeds for reciprocating pumps of various strokes are as follows: 3-in. stroke, 40 ft. per min.; 4-in., 50 ft.; 5-in., 60 ft.; 6-in., 65 ft.; 8-in., 75 ft.; 10-in., 80 ft.; 12-in., 90 ft.; 15-in., 100 ft. Many pump manufacturers rate capacities at somewhat higher speeds. A pump with shorter stroke can run with more frequent reversals, but the higher piston speed obtained with longer stroke gives greater capacity for the same diameter.

Effect of Ash on Steaming Value of Coal—Is the value of coal for steaming purposes in proportion to the heat value of the combustible ingredients of the coal? W. L. J.

Ordinarily, the efficiency of combustion decreases with the increase in percentage of ash. The greater the ash content the greater the labor and cost of managing the fire and handling the ashes and the less the efficiency and capacity. When the ash is in excess of 20 per cent. of the dry coal, the commercial value as fuel falls so rapidly with increase of ash that, for use in ordinary furnaces, coals which contain 40 per cent. of ash are comparatively worthless. A high percentage of ash may clinker and clog the fuel bed, thus requiring a higher draft, while the incombustible ingredients form insulating layers that hinder the oxygen of the air supply from coming in contact with the combustible elements of the coal, thus requiring a larger air supply and greater loss from excess air for combustion of the fuel.

Equalizing Cutoff without Indicating Engine—After setting the valves of a Corliss engine, how can the equality of cutoff be tested and corrected without indicating the engine? T. E. H.

Make a mark on the crosshead and a corresponding mark on the guide when the crosshead is at each end of its travel. To test the correctness of cutoff, block up the governor to about the medium height. Then with the wristplate hooked in gear with the eccentric, turn the engine slowly in the direction it is to run, and when the cutoff hook is detached by the cam, stop turning the engine and measure on the guide the distance traveled by the crosshead. Continue turning the engine and note the distance traveled from the other end of the stroke when the steam valve of that end is tripped. If the distance traveled is the same, cutoff will be equal for the particular height to which the governor was blocked and will be approximately equal for other positions of the governor. If the distance is not equal, adjust the length of the governor reach rods until the points of cutoff are alike.

Latent Heat of Vaporization of Ammonia*

BY NATHAN S. OSBORNE AND MILTON F. VAN DUSEN

The authors, who are physicists with the Bureau of Standards, Washington, D. C., have completed experiments in the determination of the latent heat of vaporization of ammonia, and have compiled a table both in calories per gram and B.t.u.'s per pound with a range of 40 deg. below zero to 110 deg. above. The ammonia used in the determinations was prepared by Messrs. McKelvy and Taylor of the Chemical Division of the Bureau from commercial anhydrous ammonia manufactured by the synthetic method. A statement of previous determinations is made and these determinations are plotted on a chart accompanying the article.

In tables of the heat content of ammonia, such as engineers require, the latent heat of vaporization constitutes the major part. Nevertheless the direct measurements of this property are among the rarest of the available experimental data. This is attributable probably to the fact that the latent heat of vaporization may, by thermodynamic formulas, be computed from other properties more easily measurable; however, the data which have heretofore been available for this calculation have not been of a precision such as to yield satisfactory values for the latent heat. The measurements here presented have been carried out in response to the request of the associations of refrigerating engineers of this country for more accurate data upon which to base calculations for machinery using ammonia in the production of artificial refrigeration.

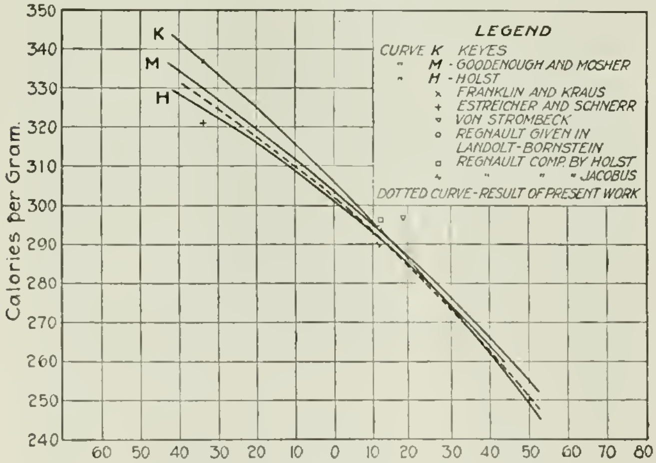

FIG. 1. RESULTS OF PREVIOUS DETERMINATIONS OF LATENT HEAT OF VAPORIZATION OF AMMONIA

Results of previous determinations of the latent heat of vaporization of ammonia are represented graphically in Fig. 1. The three curves also shown in this figure represent the values computed from other data by Keyes, Goodenough and Mosher and Holst. Regnault published a record of twelve experiments saved from the ruins of his laboratory destroyed during the Siege of Paris in 1870. The apparatus consisted of two calorimeters—the first, or evaporization, calorimeter in which the ammonia was allowed to evaporate from a steel container and flow through a chamber containing baffle plates, and the second, or expansion, calorimeter in which the ammonia vapor from the first calorimeter was allowed to expand to atmospheric pressure. The capacity of the liquid-ammonia container of the first calorimeter was 246 c.c., but it was filled with various amounts ranging from 17 to 134 grams in different experiments. In each experiment the ammonia was completely evaporated and all vapor expanded to atmospheric pressure. The observed fall in temperature in the water in the first calorimeter varied from 1.7 deg. to 13 deg., and in the second it was usually less than 1 deg. From the data obtained in the first calorimeter Regnault calculated a quantity r_1, which is the heat required to change one gram of saturated liquid ammonia at the initial temperature and pressure to vapor at the mean temperature of the experiment and at a pressure equal to a pressure in the expansion chamber in the first calorimeter.

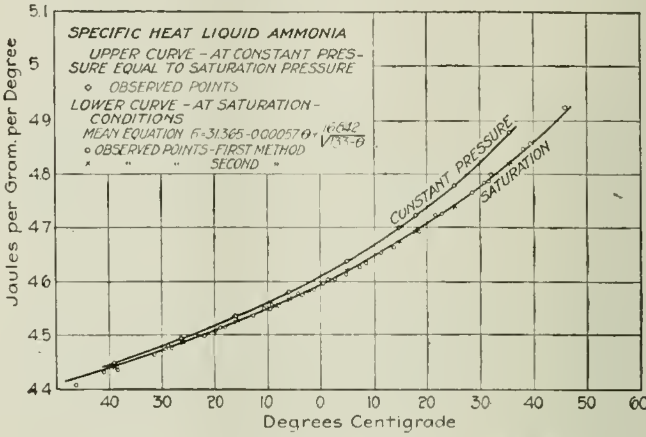

FIG. 2. SPECIFIC HEAT OF LIQUID AMMONIA

The calorimeter used in making the experimental determinations given in this bulletin is of the aneroid type and was specially designed to meet the requirements of this investigation. At this point the authors go into a thorough description of the calorimeters used, the methods of use employed, the theory of the methods and the experimental details.

The ammonia used in the determinations was prepared by Messrs. McKelvy and Taylor, of the Chemical Division of the Bureau of Standards, by methods to be described in detail in an independent paper. The sample used in the

---

*Scientific Paper No. 315, Bureau of Standards, Washington, D. C.

determinations of latent heat of evaporation was prepared in May, 1916, from commercial anhydrous ammonia manufactured by the synthetic method. Tests of the purified sample showed about one part in ten thousand by volume of noncondensing gases in the vapor phase and about one part in ten thousand by weight of water.

The latent heat of vaporization of ammonia is given in calories per gram, Centigrade degrees, and B.t.u. per pound, Fahrenheit degrees in Table I. Table II gives the vaporization of ammonia in calories per gram computed by various writers and given in their ammonia tables. The results of the present authors are included for comparison.

In Bulletin No. 313 the same authors give the results of experiments in the determination of the specific heat of liquid ammonia. The same type of calorimeter was used as in the determination of the latent heat, and the specific heat of the saturated liquid ammonia has been determined throughout the temperature interval —45 deg. to +45 deg. C. Two distinct and independent methods were used, each of which avoids sources of air present in the other. In the first method the heat added to a fixed amount confined in the calorimeter under saturation conditions and the resulting change in temperature is measured. By using data for the specific volumes of the two phases and the latent heat of vaporization, the corrections for the vapor are applied, giving the specific heat of the liquid when saturated. In the second method the calorimeter is kept full of liquid with a constant pressure. The heat added to the variable amount in the calorimeter and the resulting change in temperatures are measured. A correction for the heat withdrawn and the expelled liquid is determined by special experiments. The greatest difference between the mean results of both methods and the result of either method is represented by an empirical equation which is less than one part in one thousand. In Fig. 2 the results of all determinations by both methods are shown graphically. Fig. 3 shows the present and previous determinations of the specific heat of ammonia.

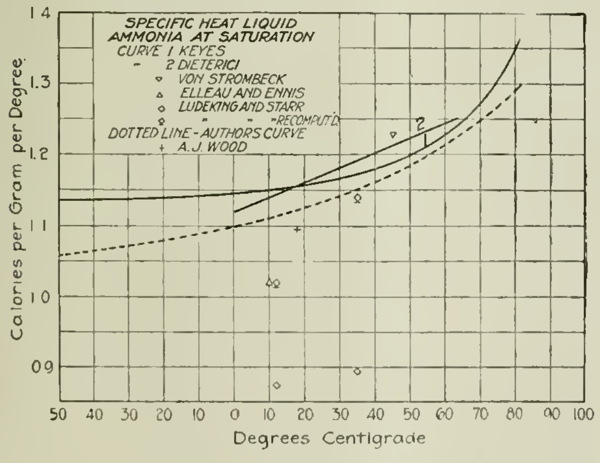

FIG. 3. PREVIOUS AND PRESENT DETERMINATION OF THE SPECIFIC HEAT OF LIQUID AMMONIA

Table III gives the specific heat of liquid ammonia under saturation conditions expressed in calories per gram per degree C. Table IV gives the heat content of the saturated liquid ammonia reckoned from the temperature of melting ice in calories per gram and B.t.u. per pound.

It is interesting to note that the result of 34 separate determinations agree with the mean within one part in one thousand. Both of these papers are now on sale, No. 315 costing 5c. and No. 313 costing 5c.; address the Superintendent of Documents, Washington, D. C.

*Heat content as used here is defined by the relation: $H = e + pv$

Where H = heat content, taken as zero at the temperature of melting ice, e = internal or "intrinsic" energy, and H, e, and pv are all expressed in the same units.

In Scientific Paper No. 314 the same authors give the results of experiments in the determination of the latent heat of pressure variation of liquid ammonia for a temperature range of —40 to +40 deg. C. This paper may be obtained free by addressing the Director, Bureau of Standards, Washington, D. C.

The War-Savings Stamp plan is a means of directing the nickels, dimes and quarters of the ordinary man into the United States Treasury for safe-keeping so that at the end of the war the poor man may find himself no less poor, if not richer, than he was at the beginning. It means "postponed" prosperity, and thus from the business point of view is a most desirable asset.

Manning the New Merchant Marine

By HENRY HOWARD
Director of Recruiting Service, U. S. Shipping Board

The Director of the Recruiting Service, United States Shipping Board, tells of how America is meeting the problem of manning her great merchant fleets. The Recruiting Service is responsible for providing the whole human side of the ships built for the Shipping Board. Qualifications required of applicants to engineering schools; names and addresses of the section chiefs to whom applications should be made.

PRESENT construction plans for our merchant marine call for more than 8,000,000 tons of new shipping, to be completed within two years. At the beginning of the world war, in August, 1914, seven nations were credited with more than 1,000,000 tons of shipping each. Great Britain headed the list, with 19,799,119 tons; the United States stood next, with 7,928,688 tons, and Germany third, with 4,892,416 tons. The other nations stood: France, 2,173,544; Norway, 2,425,476; Sweden, 1,114,048, and Japan, 1,167,264. Austria had 998,130 tons. Of the tonnage of the United States something more than 2,000,000 tons was available for deep-water service in the Atlantic.

The first year of the war was sufficient to show the United States that the process of attrition in the world's supply of tonnage, due to normal war causes and to the illegal use of the submarine by Germany, was creating a shortage of ships. This shortage became acute when the United States entered the war in April, 1917, thereby adding to the already pressing problem of logistics this country's vast needs of sea transportation for troops and supplies and the quickened need of sending more and yet more supplies to our Allies.

Coincident with the sudden awakening of the nation to the vital need for more cargo ships and the energetic initial steps of the Shipping Board to produce them came forward the question of manning the new merchant marine so soon to come into being. The country as a whole not having been accustomed, in recent times, to think in terms of shipping, appeared doubtful of its ability to produce the mariners needed to handle its new fleets. We were no longer a seagoing people, said the doubtful; we had lost the art of the sailor when the American square-rigged ship went out of use as a leader among the world's cargo carriers. Surely, our war need was pressing enough to appeal to the patriotism of Americans with a liking for the sea.

By establishing free schools in navigation at important ports and free classes in marine engineering at some of the leading technical colleges, I proposed to train enough men of the types indicated to meet the forthcoming increased demand for American deck and engine-room officers for the new American cargo ships.

On May 29, 1917, I was authorized by the Shipping Board to inaugurate the training plan, and on June 1 was sworn in as Director of Recruiting Service for the board. Three days later the first free navigation school to be conducted under the direction of the United States Shipping Board was opened, with 20 students, at the Student's Astronomical Laboratory, Harvard University, kindly loaned by the college faculty. Later, this school was transferred to the Massachusetts Institute of Technology, where it has since been maintained.

The work of organizing additional schools went on until 41 in all were established on the Atlantic, Gulf and Pacific Coasts and the Great Lakes. The response of men qualified to enter the schools was quick and gratifying as to numbers and, nothwithstanding that no man was accepted as a student who had not served two years on a deep-water vessel, the percentage of men who qualified for admission, out of the total number of applicants called for preliminary examination, was large. Many of the applicants, actuated by patriotism, expressed a willingness to leave lucrative positions ashore in order to fit themselves for service in the merchant marine in war time. Others frankly hailed with delight an opportunity to get back to the sea, which they had left because of unpromising conditions in the decade preceding the opening of the great war.

National headquarters of the new training service were established at Boston, where a floor in the Boston Custom House was set apart for its use by the Treasury Department. For administrative purposes in establishing and maintaining the schools the country was divided into sections, following closely the geographical divisions employed by the United States Steamboat Inspection Service, which from the first coöperated heartily with the Recruiting Service of the Shipping Board in maintaining the standard set by the regulations of the Department of Commerce as to the experience required of a candidate for a merchant officer's license.

Each section was placed in charge of an official designated as section chief, in whose hands were placed all details as to the administration of the schools in that section. The board was fortunate in securing as section chiefs men of professional or business training, whose patriotism led them to donate their time to this service, their compensation being merely nominal—in most instances $5 a month. Important positions at national headquarters also were filled by volunteers with special capacity for administrative work.

The section chiefs of the service are as follows: Section I, Horatio Hathaway, Jr., twelfth floor, Custom House, Boston, Mass.; Section II, John F. Lewis, 108 South Fourth St., Philadelphia, Penn.; Section III, Hardy Croom, 130 Riverside Ave., Jacksonville, Fla.; Section IV, Ernest Lee Jahncke, 814 Howard Ave., New Orleans, La.; Section V, Farnham P. Griffiths, 465 California St., San Francisco, Calif.; Section VI, William J. Crambs, 860 Stuart Building, Seattle, Wash.; Section VII, Capt. Irving L. Evans, 933 Guardian Building, Cleveland, Ohio.

SYSTEM OF INSTRUCTION

Direction of instruction in the navigation schools was placed in the hands of Prof. Alfred E. Burton, dean of the Massachusetts Institute of Technology, who formerly was connected with the Coast and Geodetic Survey and who is a practical navigator of wide scientific knowledge.

The system of instruction perfected for the schools was in accordance with the most approved methods of teaching navigation. It was therefore possible to impart to a student in six weeks' study a groundwork of the theory and practice of navigation to enable him to pass the examinations of the United States Steamboat Inspection Service, entitling him to a license as a second or third mate. The examinations were conducted without any modification of the regulations applying to ordinary applicants for a license. After they had been passed, the student in need of practical experience on a steamer was sent to sea in the capacity of a reserve officer, for a period of two months to learn the ropes before actually assuming the full responsibilities of the position for which he was licensed. During this period he was paid $75 a month. Afterward he received the usual pay for his grade in the merchant service.

Since the opening of the first school in navigation by the Recruiting Service of the Shipping Board, 39 others have been opened. The graduates from these schools, in the ten months from June 1 to Apr. 1, numbered 1500.

ENGINEERING SCHOOLS

The development of the engineering schools was contemporaneous with that of the schools in navigation. The training of engineers was placed in the hands of Prof. Edward F. Miller, of the Massachusetts Institute of Technology, and classes were established at the following places:

Massachusetts Institute of Technology, Cambridge, Mass.; Stevens Institute of Technology, Hoboken, N. J.; Bourse Building, Philadelphia, Penn.; Johns Hopkins University, Baltimore, Md.; Tulane University of Louisiana, New Orleans, La.; Case Schools of Applied Science, Cleveland, Ohio; Armour Institute of Technology, Chicago, Ill.; University of Washington, Seattle, Wash. The school at Hoboken was later discontinued, and one was started at the Seamen's Church Institute in New York City.

The course in the engineering schools is of one month's duration. The qualifications for admission to these schools differ slightly from those required for admission to the navigation schools, as men with proper technical experience are admitted who may require as much as six months added training at sea before becoming eligible for licenses.

Experience required for an applicant to qualify for admission to enter one of these Shipping Board Engineering Schools is classified as follows: Three years as fireman, on ocean or coastwise steam vessel; two years as oiler or water tender (or combined service of two years in these positions); six months as chief or assistant engineer, on lake, bay or sound steamer; one year, chief or assistant, river steamer; one year as locomotive or stationary engineer (with six months' sea service, which may be obtained after finishing school course); graduation from engineering class of nautical schoolship; graduation in mechanical engineering from a technical school (with six months' sea service); one year in charge of stationary plant of not less than 1000 hp.; three years as apprentice to machinists' trade (with six months' sea service).

About 1200 marine engineers were graduated from the Shipping Board free engineering schools in the first ten months of their existence. Like the dock officers graduated, all were American citizens.

One noticeable effect of the Recruiting Service's call for Americans qualified to serve as officers in the new merchant marine was the stimulation given men qualified to take examinations for licenses, without special schooling. Large numbers of such men, excellent mariners and citizens, secured licenses on their own initiative, without attending the Shipping Board schools, as is shown by the unprecedented number of licenses granted from June 1, 1917, to Feb. 1, 1918, by the Steamboat Inspection Service. Not less than 3600 original licenses were issued in that period—including those issued to the men specially trained by this service—while not less than 900 licenses were extended or transferred from fresh waters to salt; while to Apr. 1, 1918, the number of new and extended licenses was more than 5000.

THE SEA SERVICE BUREAU

As a necessary adjunct to its training service for officers, the Recruiting Service in July, 1917, established a department whose functions are indicated by its title, the Sea Service Bureau.

Graduates of the schools were placed on board ship by this department, at first entirely through the coöperation of private steamship interests, and later also on ships controlled directly by the Shipping Board.

TRAINING MERCHANT CREWS

By the autumn of 1917 the construction program of the United States Shipping Board, by which considerably more than 1000 new ships will be commissioned under our flag, had advanced sufficiently to warrant the development of the second phase of the training plan originally submitted to the board for manning the new merchant marine; namely, the training of crews.

Much thought was given by the Recruiting Service staff to working out a system of intensive training for crews, by the use of a squadron of training ships. In December the Shipping Board approved the resulting detailed plans, and on Dec. 12, 1917, announcement was made in the press that the Recruiting Service was prepared to receive applications from young Americans between 21 and 30 who wished to be trained for service on merchant ships as sailors, firemen, coal passers, oilers, water tenders, cooks and stewards. In the three months following this announcement more than 7500 applicants sent their names to the Recruiting Service headquarters, Custom House, Boston, Mass.

The number of men required for this branch of the training service was at first estimated to be 85,000; but events subsequently led to a modification of this figure. The transportation of an immense American army to France, and of its supplies, called for the taking of a great many ships from the merchant marine. The need of arming all ships entering European waters with naval guns led to a proposal that all ships crossing the submarine zone be manned by the Navy. After several conferences on this point between officials of the Navy Department, the War Department—then operating the troop ships—and the Shipping Board, a decision was reached by which control of troop ships, animal transports and freighters carrying unbroken cargoes of munitions and supplies for military uses were placed in control of the Navy, to be manned by Naval crews, while Atlantic passenger liners, freighters with general cargoes for our Allies and all merchantmen plying outside the war zone were left in the control of the Shipping Board.

Work in training the new crews was begun the day the board's authority was granted me to proceed with the plan. To administer the training service, a department was created, termed the Sea Training Bureau, with a supervisor of training in charge.

For the training squadron two steel screw steamers were at once secured, the "Calvin Austin" and "Governor Dingley," twin ships, formerly in the passenger trade on the New England coast, each being of 3800 tons gross register, 299 ft. long and 60 ft. wide, with reciprocating engines and 2700 i.hp. Each vessel had a rated capacity for 783 passengers. Being speedily converted into training ships, the vessels each had capacity from 500 to 600 apprentices. Because of the large number of applicants it was possible to select superior material for their complements, which filled rapidly in the first weeks of 1918.

While these two ships were being filled, a third was being fitted out at Newport News. This was the former transport "Meade," ex-"City of Berlin," a graceful old Atlantic liner, with a sound hull and capacity for more than 1200 apprentices. It was planned to take this ship also to Boston, to be used as a station ship, while the other two made frequent training trips to sea. Later, a fourth ship, the "Governor Cobb," of the type of the two first-named, was put into the training squadron, and plans were put on foot for placing a training ship on the Pacific Coast and another at New Orleans.

The training course is of an intensive character. There is an instructor to each ten apprentices, and he is held responsible for the progress of his group. The apprentices virtually go to school all day, and every day except Sunday, during their stay on the ship, which is not less than a month in any case, and will probably exceed two months in few.

When the apprentices have finished their intensive training, they are added to regular crews in the merchant marine, on a given ratio to the experienced men carried. By this method it is expected that no difficulty will be experienced in securing full crews for all ships added to the merchant fleet by the Shipping Board, as well as for any existing ships that may need men.

In perfecting a plan for enrolling apprentices for its training ships, the Recruiting Service availed itself of the offer of a patriotic citizen of Boston, Louis K. Liggett, head of large interests in the drug trade, controlling nearly 6900 drug stores in 6393 cities and towns.

The young men accepted for training by the Shipping Board Recruiting Service are placed on pay at $30 a month for their period of training and are exempt from military service as long as they remain in the merchant marine, either as apprentices or as members of regular crews.

[Those applying for service as engineers aboard ships of the United States Shipping Board or for training at the various engineer schools of the board should address their applications to the headquarters of the section chiefs nearest their homes, or to United States Shipping Board, Recruiting Service, Custom House, Boston. This does not apply to the Navy or the Naval Reserve.—Editor.]

Centrifugal Pumps for Mine Service*

The experience of many years with a large variety of pumps forms the basis of this article. Although the theory of the centrifugal pump as usually set forth by writers on this subject is somewhat complicated, the machine itself is simple. Its successful installation and operation require only care and judgment.

FOR anyone wishing to study the theory of centrifugal pumps, there are three or four books in the English language devoted to the subject upon which he can devote as much energy as he desires. There are a few rules, however, that it is well to remember; namely, for equal efficiencies the power required to drive the pump varies as the cube of the speed, the head as the square of the speed, and the capacity directly as the speed. The head in feet that any impeller will work against is approximately the diameter of the impeller in inches times the revolutions per minute divided by 1950 squared, or $H = \left(\frac{d \times r.p.m.}{1950}\right)^2$.

The most distinctive part of the whole machine is the impeller, the function of which is to take the slowly moving water in the suction pipe and, by revolving create by centrifugal force a velocity head in the water convertible into a pressure of sufficient intensity to overcome the static and friction heads of the discharge pipe. The impeller is mounted on a shaft carried by bearings, and is inclosed in a casing. The shaft is connected to the driving element. This is, in a general way, all there is to a centrifugal pump.

The casing should be so designed as to be readily opened, giving access to the entire inside of the pump. This is most readily accomplished by employing the so-called horizontally split casing that has the suction and discharge openings on the bottom half which is bolted to the baseplate. Such an arrangement permits the top half of the casing to be removed without breaking any pipe joints or disturbing the alignment of the pump—considerations that are of great importance when repairs have to be made in a hurry.

VERTICAL SPLIT SUPERIOR TO HORIZONTAL

The horizontal split is not so good mechanically and structurally as the so-called "vertical split," in which the annular portion of the casing is in one piece and the internal parts are withdrawn from the end, after removing the end plate which usually forms the suction pump-head. But this procedure necessitates the breaking of the suction-pipe joint. Furthermore, the parts must be pulled out one at a time—first the impeller, then the diffusion ring, next that part of the casing forming the return guide for the water to the second impeller, then the second impeller and so on—a long, tedious job, especially in large units.

In putting the parts together, the reverse order must be followed and care must be taken to insure that all the parts come to place properly, in order to prevent them from overlapping and partly closing the water passages in the casing. In such cases reliance must be placed entirely upon careful measurements; and it is very hard to make men to whom a foot more or less is good enough understand the importance of measuring to 1/16 or 1/32 in. or less. With the horizontal split, as before stated, after lifting the top half off the machine all internal parts are in view and can be removed readily. Furthermore, before the top half of the casing is replaced one can *see*—not feel—that everything is as it should be.

The ends of the casing through which the shaft projects are provided with stuffing-boxes and glands. The stuffing-boxes should be deep enough to take not less than four or five rings of good soft packing. The glands, preferably made in halves, should fit tight in the box but be about 1/16 in. larger than the shaft. To the back of the stuffing-box renewable rings should be fitted, so that if they become worn and allow the packing to be squeezed into the pump, they can be replaced. The stuffing-box on the suction side particularly when the pump is working under a suction lift, should be provided with a water seal to prevent air being drawn into the pump and also to lubricate the packing with water.

Removable rings should be provided around those parts of the casing in which the impeller or other moving parts revolve, so that in case of wear—which is bound to occur even under the best conditions and quite rapidly when pumping acidulous mine water—these rings can be replaced.

One of the chief causes of loss in efficiency of centrifugal pumps is internal leakage between a stationary and a revolving element, prevented only by a close running fit. There are several types of labyrinth rings used, the idea being that the water has to traverse a narrow, tortuous passage which it can follow only with difficulty. These rings may have merit when good, clear water is pumped, but for mine use a plain straight ring is preferable. This should have a width of ¾ to 2 in., with a running clearance of 0.006 to 0.01 in., depending upon the size of the impeller and, except for the larger sizes when fresh water is used, should be of bronze.

In modern pumps the impellers are of the inclosed type, with the blades or vanes curving backward, making an angle of from 12 to 24 deg. with the outer diameter.

THIN BLADES CORRODE QUICKLY

Originally pump builders thought that the impeller blades should be as thin as possible, with the tops cut to a knife-edge, but this was found to be a fallacy, especially in bad water, for the thin blades corroded quickly and the knife-edges doubled over and closed the port openings. The impeller walls and blade should be 5/16 in. thick for 12-in. diameter impellers and ⅝ in. thick for 24-in. and larger impellers. With such impellers higher initial efficiency, far better average efficiency and much longer life are obtained than with thinner blades. Impellers should be provided with renewable wearing rings where they fit into the casing. These rings can be shrunk on, and all rotating elements should be balanced.

Some builders claim that diffusion vanes are essential to obtain high efficiency with multistage pumps. Others assert that they can get just as high efficiency without them. Diffusion vanes, which are stationary plates with guide vanes curved in an opposite direction to the impeller blades, are arranged to encircle the impeller and receive the water discharged from the impeller tips at high velocity, and by reducing its speed convert velocity head into pressure head. The usefulness of diffusion vanes is not always apparent, since by actual tests of different makes of two-stage pumps, under about the same operating conditions (one with and one without diffusion vanes) their efficiencies were found to be practically the same. If diffusion rings are used, they should be of bronze; and provision should be made to prevent their turning in the casing and to prevent leakage around the vanes.

The pump shaft should be of steel protected by cast-bronze sleeves or bushings placed over all parts of the shaft that come in contact with the water. The end bushings should project through the stuffing-boxes and form the nuts that keep the impeller in place laterally. Provision should also be made to prevent leakage along the axis of the pump shaft, which can be done by inserting fiber gaskets 1/16 in. thick between the impeller hubs and the ends of the bushings.

Impellers should fit snugly on the pump shaft, but need not necessarily be a driving fit, and they should be secured from turning by bronze (not steel) feather keys. The pump shaft, when hung in its bearings, should be large enough in diameter to support the weight of the impellers and the column of water without perceptible deflection, so that the internal sealing rings and bushings will not be

---

*Abstract of an article by Herbert Axford, pump inspector, Coal Department, Delaware, Lackawanna & Western R.R., Scranton, Penn., in *Coal Age*.

required to support any weight. In many instances the undue wear of sealing rings has been directly due to the pump shaft deflecting under load.

Bearings should be of the ring-oiled type with renewable liners in halves. Bearing boxes should be provided with bolted caps, so that the bearing liners may be renewed or rebabbitted without removing the shaft; and so that when the top half of the casing is removed together with the bearing caps, the complete rotating element can be lifted from the pump.

One of the most important details in a centrifugal pump is the thrust bearing. Unbalanced end thrust causes a great deal of trouble to the operator and it is oftentimes difficult to locate and remedy the defect. Theoretically, every pump leaving the factory is hydraulically balanced. The double suction impeller has inlets of the same diameter on each side and the impellers thus having the same pressure on each side are perfectly balanced—on paper. But let one side get choked or one side take more water than the other, or the leakage through the sealing rings on one side be more than on the other, then an unbalanced condition is immediately established.

This unbalanced pressure has to be carried by the thrust bearing. There is also the single-suction impeller, wherein the water enters on one side only. This is balanced by putting a duplicate set of sealing rings back of the impeller. Holes drilled in the rear wall of the impeller connect with the inner chamber formed by the sealing rings and thus balance the pressure in this chamber with that of the suction. Sometimes some of these holes have to be plugged or enlarged in order to equalize the end thrust.

There is also the "back-to-back" type of impeller, where the suction on one impeller or one set of impellers is on the left-hand, while the suction of the other (or the other set) is on the right-hand side. This arrangement should form a perfect end balance, and yet the thrust bearing may get red hot after a few minutes' run.

Large Marine-Type Thrust Bearings Satisfactory

The most satisfactory bearing for all ordinary purposes is the marine thrust type—that is, a series of steel collars running between babbitted collars, plentifully supplied with oil. Such a bearing is preferably run in a bath of oil with the thrust box water-cooled to keep the lubricant at normal temperature. Furthermore, this thrust bearing should be made large.

Several companies are building pumps in which hydraulic balance is effected by water leaking from the discharge side of the impeller into a balancing chamber and then out past a balancing disk, which rotates with the pump shaft, into the suction side of the pump. This device works automatically and gives satisfactory service where the water is clear and free from grit and acid, but it soon becomes useless when pumping acidulous or gritty water.

The couplings which connect the pump and motor shafts should not be any heavier than necessary, and should be of the pin-and-buffer type to allow a certain amount of end play without putting stress on the thrust bearing of the pump.

The baseplate should be of cast iron, heavy enough to resist distortion if the pump be subjected to careless handling during erection, or if the foundation settles a little.

Although some of the points mentioned may seem trivial and others self-evident, they must all be watched carefully. If the front or inner bearing of some pumps should burn out—an occurrence by no means uncommon—it would be necessary, in order to replace the bearing, to move the whole pump from its base, break the suction and discharge connections and remove the coupling from the shaft. If the men who designed such pumps were compelled to repair them in a mine while the water was rising over their shoetops at the rate of an inch a minute, there would soon be a radical reform in the design.

Another matter for investigation is the use of small screws, dowels or pins on the inside of the pump. Some builders—in fact the majority—can think of only a small screw or dowel to prevent a ring or bushing from turning, but acidulous mine water eats these small parts out so quickly that they are useless, and when they give way they seem to have the habit of lodging between some stationary and rotating element, thereby cutting grooves and ridges and almost ruining the machine.

The best speed to drive centrifugal pumps is a much-debated question. Just now builders of pumps and motors seem to be advocating high rotative speeds to secure efficiency, but for mine use moderate speed is preferable wherever possible, as less trouble is then experienced with both pump and motor. Elsewhere the higher-speed pumps apparently give good service. For 75 or 100 hp. and upward 900 r.p.m. is satisfactory; for 30 to 50 or 75 hp. 1200 r.p.m., and for smaller pumps 1500 to 1800 revolutions per minute.

The head per stage is another open question; but, in general, pumps working under 100 ft. per stage have a longer life than those working over 100 ft. per stage. Consequently, until further evidence is produced, it seems best to keep close to 100 ft. per stage as the maximum.

The centrifugal is about the simplest pump to operate when a few conditions are complied with. For example, means must be provided for priming or filling the machine with water. Where the pump is placed below the source of water supply, it is primed as soon as the valve in the suction pipe is opened and all entrained air is allowed to escape from the casing; but when the pump is placed above the water supply, some provision must be made for filling it, somewhat as follows:

Where pumps are to work under heads of less than 400 ft., a foot valve is placed on the suction pipe near to, and preferably submerged in, the water (not necessarily at the deepest or lowest point of the suction pipe, where it would be hard to reach in case of any trouble) and water is admitted into the discharge pipe at a point sufficiently above the pump to completely fill the pump casing. This method is usually adopted around mines, since when the pump is shut down a valve in the discharge pipe is closed.

The tail pipe, an important part of the installation, must be air-tight and laid so as to prevent the formation of air pockets; it must also be of sufficient diameter to avoid excessive friction. No attention should be paid to the size of the suction opening on the pump, for it will usually be found that such openings are one or two sizes too small except for short suction lines and light suction lifts. To start a motor-driven pump it is necessary only to prime it and start the motor.

Don'ts for Pump Runners

The following don'ts for pump runners cover all ordinary operating points:

Do not run a pump without water.

The numerous bushings and sealing rings on the inside of a pump depend on water for lubrication, and if the pump is run without being first filled with water these parts will get hot and "freeze," doing great damage to the pump.

Do not run without oil in all the bearings.

Do not run with dirty oil in the bearings.

Do not let water get into the bearings.

Before starting up, see that the bearings are full of clean engine oil and that there is no water in the boxes. This can be done by loosening the drain plug on the bottom of the box to see if clean oil comes out and by measuring the depth of oil in the box. Do not rely altogether on the oil-level gage, as this sometimes gets choked up. To keep the bearings clean, drain all oil out of the boxes once a week and thoroughly wash out with two or three bucketfuls of water. The old oil should be filtered and used over again if it is not too gummy.

Do not run the stuffing-box glands tight.

This produces unnecessary friction, causing the boxes to heat up and the packing to burn out. Having the glands loose and allowing them to leak a little keeps the packing lubricated and the stuffing-boxes cool.

Do not run with leaky joints around pump.

This is unnecessary, and if not stopped in time will ruin the joint faces.

Do not allow water to collect around the motor.

Keep the baseplate of the pump clean, for when the motor is running the air suction produced draws the dirt and moisture into the motor.

Do not run a pump or motor that vibrates excessively.

This is caused by the machines not being in balance or line. It should be reported at once.

Do not run unless you are satisfied that all parts are in good condition.

Do not allow oil, grease or dirt to accumulate anywhere in the pumproom.

If properly cared for, a centrifugal pump will run with little trouble.

The advantages of centrifugal pumps are briefly as follows: Small floor space is required, therefore they can be installed in a small pumproom. The machine is light in weight, therefore it is easily handled in close places and requires no expensive foundation; in fact it can be set on skids. It can be quickly installed and can be direct-connected to an electric motor, dispensing with noisy and troublesome reduction gearing. It has no valves or plunger packing, therefore will have no packing or valve troubles. It gives a steady flow of water without shocks, can be started with the column line full, and furthermore, cannot do itself or pipe lines harm should the line become blocked or if someone forgets to open the valve on the discharge line before starting. Last, but by no means least, it is a reliable pump, with a minimum cost of maintenance, except possibly where the water is extremely acidulous or gritty.

Pumps Should Be Accurately Aligned with Motors

Centrifugal pumps should be set on a fairly good base and accurately lined with their motors. Although pumps are usually coupled to their motors by so-called "flexible" couplings, these are not flexible in the sense that they are a sort of universal joint. They simply permit end motion, and although they permit operation with the pump and motor slightly out of line, trouble will eventually follow. Piping should be connected to the pump squarely and accurately, for it is possible to strain and distort the pump casing if force is used to bring the piping and pump connections in line. As stated previously, provision should be made for priming the pump. Check valves should be installed in the column pipe with a bypass around so as to drain the line. When the capacity has to be regulated by throttling, a gate valve must also be installed in the discharge pipe line; in fact, when the water is not highly acidulous, it is wise to install both a gate and check valve in all column pipes. But where the water is extremely acid, it has been found that the gate valves wear out quickly and that good leather-faced check valves last so much longer that the gate valve is omitted and reliance is placed entirely on the check valve.

The strainer on the end of the suction pipe should have the mesh, or size, of the holes so small that nothing will pass through which is likely to lodge in and block the impeller. The total area of the holes should be two or three times that of the suction pipe. There should be no less than four feet of water over the strainer, for it is possible to draw air bubbles down through even four feet of water, especially if the velocity is high. Provision should be made for water-cooled bearings, water seals on the suction glands, and the air vents should be piped properly. With the larger machines, provision should be made for handling the heavy parts—that is, for taking off the top half of casings, and removing the shaft and impellers by means of a hand crane or chain hoist. If these few common-sense directions are followed and good water is pumped, the machine will run satisfactorily for years. If the water is acidulous it is necessary merely to change the sealing rings; on the quality of the water the frequency of such renewals depends. If gritty the grit gets in between the fast-moving internal parts and acts like a grindstone, cutting the normal working clearance of $\frac{1}{100}$ in. to ⅛ or ¼ in. in a very few days.

The maintenance of pumps is a simple matter as the parts most subject to wear are the shaft bearings, the shaft sleeves in the stuffing-boxes, the sealing rings on the impellers, together with the distance and stage bushings in multistage pumps. These last-mentioned parts generally wear rapidly, and it is an excellent plan to keep an extra pump rotor on hand—that is, a shaft with impellers, rings and shaft sleeves—also an extra set of bearing liners. Then, when the pump declines in capacity (which is a general sign that the sealing rings are worn, allowing too much internal leakage or short-circuiting of the water) it is an easy matter to open the machine, remove the old rotor, put in the new one and bring the pump back to its original capacity and efficiency. The old rotor is then sent to the shop to be rebushed and held in readiness for further use.

If this is done before the pump gets too badly worn, the operation can be repeated many times and the cost of repairs reduced, but the repairing must be done in a careful and painstaking manner or the repair costs and troubles will more than double.

A restricted suction will cut down the capacity of the pump and give excessive end thrust. A leaky suction pipe will also cut down the capacity and give an unsteady and fluctuating pressure and flow and produce excessive vibration and noise in the pump.

If the holes in the strainer are so large that chips of wood, coal and other substances enter the pump and block the impeller vanes, trouble ensues.

Thrust-bearing troubles can be greatly reduced if large thrust bearings provided with an efficient oiling system are used. When abnormal thrust occurs, as before mentioned, examine the suction line first; then if the trouble is not located, open the pump and see if one set of sealing rings is worn more than another.

Efficiency of Centrifugal Pumps Low

Centrifugal pumps are not recommended as a rule for capacities of less than 300 gal. per min., and even for this capacity the head should not exceed 60 ft. For heads of 100 to 150 ft. 500 gal. per min. is considered the minimum, but for capacities of 1000 gal. per min. it can be used for almost any head with fairly good efficiency. Two 1500-gal. eight-stage pumps working against a total head of 820 ft. have been in successful operation for two years, giving a pump efficiency of about 68 per cent. The efficiency of the centrifugal pump is generally low. A 300-gal. pump gives about 50 per cent., a 500-gal. pump about 55 per cent. and larger pumps give anywhere from 55 to 72 per cent. efficiency. This latter efficiency is the highest of which the writer has actual knowledge, and that was secured from a machine of large capacity working under a moderate head.

Each centrifugal pump must be built for a certain capacity and head at a given speed, and it is herein that the maximum efficiency lies, because the capacity and head cannot vary materially from these fixed conditions without a considerable loss in efficiency. This means that a centrifugal pump built for a certain head and driven by a constant-speed motor cannot be used for any other head, much greater or less, without sacrificing efficiency, and the capacity when driven at a constant speed cannot be changed or varied except by the uneconomical method of throttling. These points should always be taken into consideration.

The steam-turbine-driven centrifugal boiler-feed pump has been well received, but is not recommended for boiler plants of less than 3000 rated horsepower, since small ones are unusually run at such high speed that it does not take much to put them out of order. Furthermore, the first cost, steam consumption and upkeep will be high. For plants of 8000 hp. or over, they are superior to the plunger pump, but between 3000 and 8000 hp. the selection hinges largely upon local conditions and individual preference.

The Latent Heat of Steam

The latent heat of steam at standard pressure and temperature is a fundamental constant, the value of which has long been less satisfactorily known than was desirable. The values given in Kaye and Laly's "Physical and Chemical Constants" differ appreciably, ranging from the 537 calories of Regnault obtained in 1847 to the 540 calories found by Joly in 1895. In Callendar's steam tables the value 539.3 is adopted. A new determination is described in a paper by T. Carlton-Sutton, published in a recent issue of the *Proceedings* of the Royal Society. The plan of the experiments consisted in weighing the quantity of steam condensed upon a bulb, both when empty and when filled with water. From the two observations the latent heat can be deduced, the value found being 538.88 mean calories. It is claimed that this figure is correct to the fourth significant figure.—*Engineering.*

Some Fundamental Considerations of Power-Factor Correction*

By R. A. McCARTY
Engineer, Westinghouse Electric and Manufacturing Company

What the power factor of an alternating-current circuit is and its effects upon the capacity of generating and transmitting equipment are discussed, and the use of synchronous machines as a means of correcting the power factor is considered.

THE power factor of an alternating-current circuit may be defined as the ratio of the actual energy in kilowatts to the apparent energy in kilovolt-amperes, expressed in percentage. For example, if the kilowatt load on a circuit is 1000 and the kilovolt-ampere load 1250, then the power factor of the circuit is 1000 ÷ 1250 = 0.80, or 80 per cent. This relation between actual and apparent energy is dependent on the relative "phase" position, with respect to time, of the current and voltage of the circuit, which in turn is fixed by the characteristics of the circuit and the connected apparatus, as will be mentioned later.

In any alternating-current circuit if both the voltage and current pass through corresponding instantaneous values, that is, pass through zero and maximum points, simultaneously, they are said to be "in phase." When this condition exists, the actual and apparent energies are equal and the power factor is 100 per cent. If, however, the voltage passes through any given instantaneous value before or after the current passes through the corresponding value, the two are "out of phase." When this condition exists, the true energy is less than the apparent energy and the power factor is something less than 100 per cent. If curve *A*, Fig. 1, represents voltage and curve *B* the current in phase with the voltage, then curve *D* will represent a current out of phase with the voltage.

The latter condition is the immediate result of the reactive, or wattless, current present in the circuit. In any alternating-current circuit having a power factor less than 100 per cent., the current that flows is made up of two parts, the energy component in phase with the voltage and the reactive component, which leads or lags behind the voltage 90 electrical degrees. These two components of the current, therefore, bear a 90-deg. relation to each other and combine geometrically to give a resultant current that lags or leads the voltage by an angle less than 90 degrees.

Again referring to Fig. 1, if curve *A* represents the voltage and curve *B* the energy component of the current, then curve *C* will represent the reactive component and curve *D* the current that results from the combination of *B* and *C*. Assuming a direction of phase rotation from right to left, the current represented by curve *D* lags behind the voltage *A*.

The reactive current in any circuit is due to inherent characteristics of certain apparatus such as induction motors, transformers, reactance coils, arc lamps, etc., which make them draw from the source of supply, not only the work current which transmits the useful energy but reactive-magnetizing current as well. Since the reactive current not only transmits no useful energy but has the detrimental effect of causing increased losses, which appear in the form of heat, in the transmission line, transformers and generating apparatus, thereby reducing their useful capacity, it is obviously desirable to reduce to a minimum or neutralize the effect of such current. The very marked increased heating, for a given rating, or the reduction in rating, of the generating apparatus, which results from low-power-factor loads will be mentioned later.

In practically all commercial circuits the demand for lagging reactive current predominates to such an extent that it is seldom if ever necessary to consider the case of leading current in connection with power-factor correction alone. For that reason all further reference will, unless otherwise stated, presuppose a condition of lagging power factor.

There is at the present time but one commercially successful type of apparatus for general application of neutralizing the effects of lagging reactive current. This apparatus consists of overexcited synchronous motors used either to deliver part of their capacity in mechanical load and the remainder in corrective effect, or their full capacity as corrective kilovolt-amperes. Under the latter condition they are usually termed synchronous condensers.

Any synchronous motor, when operated with a field excitation just sufficient to set up the flux required to generate a counter-electromotive force which equals the impressed electromotive force minus the ohmic and reactance voltage drops in the armature winding, will draw from the line a current in phase with the voltage, therefore operates at 100 per cent. power factor. Other things remaining constant, if this field adjustment is varied the motor will in addition to taking the energy current required, draw from the supply a reactive current which either opposes or assists the current in the motor's field winding in maintaining the flux required for the counter-electromotive force. With the motor's field underexcited, the reactive current drawn from the line is a magnetizing current, in the same sense as that drawn by an induction motor; that is, it lags behind the line voltage, thereby tending to still further reduce the power factor of the total system. For this reason it is very important that the field excitation of a synchronous motor should always be adjusted to its proper value. If, however, the field is overexcited the reactive current drawn from the line is a demagnetizing current and leads the line voltage. Therefore it is possible to neutralize the effect of any lagging reactive current by introducing into the system a like amount of leading current. As previously indicated, the required leading reactive current may be introduced into the system by using a synchronous motor of the proper capacity, operating with an overexcited field.

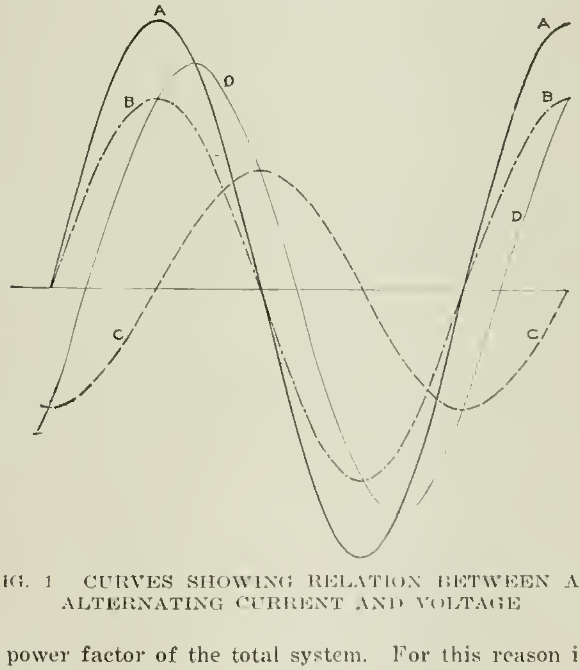

FIG. 1 CURVES SHOWING RELATION BETWEEN AN ALTERNATING CURRENT AND VOLTAGE

The questions of proper corrective capacity, its location in the system, whether it shall be in one or more units and

---

*A paper presented before the Iron and Steel Electrical Engineers and the Pittsburgh Section of the American Institute of Electrical Engineers at Pittsburgh, January 12, 1918.

whether the machines shall deliver both mechanical energy and corrective effect or only the latter, have, of course, to be determined for each particular case. The detail conditions which ordinarily determine the decisions in regard to these points are beyond the scope of this discussion, but one or two principal factors may be mentioned. There are several accurate but more or less involved methods for determining the required corrective capacity for any given case, but all this becomes unnecessary and the problem extremely simple if we keep in mind the fundamental principles; namely, that the leading and lagging reactive currents are in opposition, hence the resultant reactive current is the algebraic difference; that the reactive current is 90 deg. out of phase with the energy current; that the resultant current is the geometrical sum of these two; and that the power factor of the system is the ratio of the kilowatt to the kilovolt-amperes.

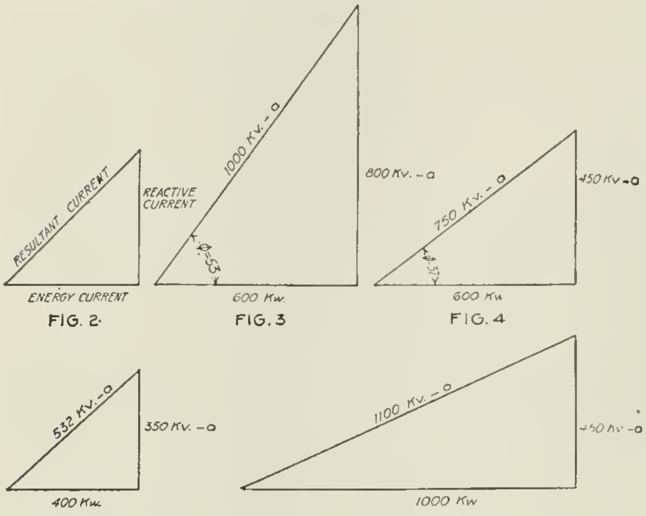

FIG. 2 FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 2 TO 6. SHOW THE RELATION BETWEEN ENERGY, REACTIVE AND RESULTANT CURRENTS

Expressed geometrically, the energy current, reactive current and resultant current form a right-angle triangle, Fig. 2, in which the base represents the energy current, the vertical line the reactive current and the hypotenuse the resultant current, as indicated. Since, if the currents in the system bear these relations to each other, the kilowatt, reactive kilovolt-amperes and resultant kilovolt-amperes must bear the same relations, we will for convenience use the same triangle to indicate the latter quantities.

Assume, then, a system having a load of 1000 kilovolt-amperes at a power factor of 60 per cent. and it is required to find the corrective kilovolt-amperes to raise the power factor to 80 per cent., and the resultant total kilovolt-amperes of the system. To determine the lagging reactive kilovolt-amperes of the system, refer to the triangle, Fig. 3, the hypotenuse or total kilovolt-amperes is 1000, the base or energy is 60 per cent. of this value or 600 kw. and the vertical side or reactive kilovolt-amperes is found, by solving the triangle, to be 800 kilovolt-amperes. Repeating this construction for the system with a power factor of 80 per cent., the kilowatt will of course remain constant at 600, Fig. 4. Since the power factor can be expressed as the cosine of the angle between the resultant kilovolt-amperes, and the kilowatts, or in this case equals 0.80, the angle between the resultant kilovolt-amperes and kilowatts will be that having a cosine corresponding to 0.80. or approximately 37 deg. Then drawing the hypotenuse at an angle of 37 deg. to the kilowatt line and completing the right triangle, it will be found that the resultant total kilovolt-amperes will be 750 and the reactive kilovolt-amperes 450. Obviously, then, the required corrective kilovolt-amperes to produce this result is the difference between 800 and 450 or 350 kilovolt-amperes. If this corrective kilovolt-amperes is obtained by a synchronous condenser, its rating will be 350 kilovolt-amperes. If this corrective effect is to be obtained from a machine that is to deliver mechanical energy as well as the corrective effect, the rating of this machine is found as follows:

Assume that the motor is to deliver 500 hp. and at the same time supply 350 kilovolt-amperes corrective effect; determine the capacity of the motor and the final total kilovolt-amperes of the system. Allowing for the efficiency of the motor, it would have a kilowatt input of 400. Combining this as before at right angles, with the 350 kilovolt-amperes (Fig. 5) the corrective kilovolt-amperes rating of the motor is found to be 532. The total kilovolt-amperes of the system then becomes the resultant of 1000 kw. (sum of original 600 kw. and additional motor 400 kw.) and the uncompensated reactive kilovolt-amperes of 450. These, combined as before at right angles, give a total system kilovolt-amperes of approximately 1100, Fig. 6. It should then be noted that the addition of the 400 kw. energy load, in addition to the 350 kilovolt-amperes corrective capacity has resulted in raising the power factor of the total system to 1000 ÷ 1100 = 0.91, or 91 per cent.

The location in the system of the machine delivering the corrective effect should, to obtain the greatest gain, be at or near the source of the lagging reactive current. Otherwise the reactive currents have to be transmitted over the intervening lines, and through transformer, switches, etc., causing additional losses.

The question of using synchronous condensers or partly mechanically loaded motor for this service largely depends on the questions of capacity required and the relative locations of the demands for mechanical energy and corrective effect. In general, if the two are combined, the first cost of the required apparatus is less and the cost of buildings and maintenance is less.

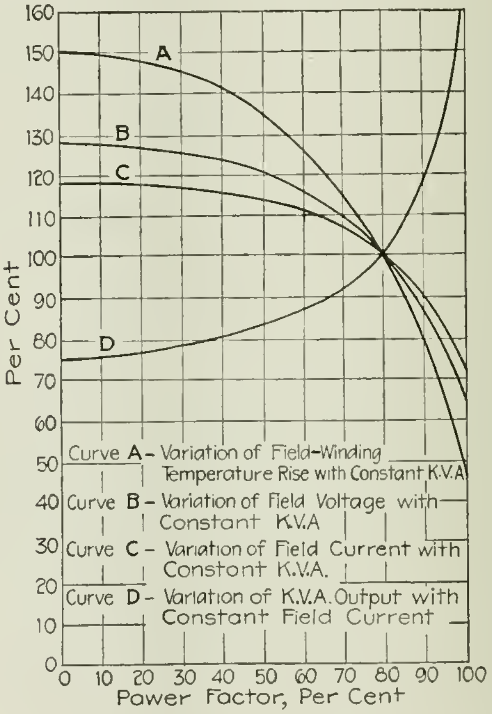

FIG. 7. SHOWS VARIATION IN ALTERNATOR PERFORMANCE WITH CHANGE IN POWER FACTOR

To show this point in a concrete way, the relative cost of a motor-generator set consisting of a 1000-kw. 250-volt direct-current generator driven by a 2200-volt three-phase 14-pole 60-cycle 80 per cent. power-factor synchronous motor was compared to the cost of a set of the same capacity except driven by a 100 per cent. power-factor motor with a separate 8-pole synchronous condenser having the same corrective capacity as the 80 per cent. power-factor motor (approximately 850 kv.-a.). This comparison showed that the 80 per cent. power-factor motor set has a first cost of 90 per cent. of the other machines and only 80 per cent. of the losses. A notable installation of this kind is now building for the Tennessee Coal, Iron and

Railway Co., consisting of five 750-kw. direct-current generators driven by 1500-kv.-a. motors. These motors, in addition to driving the generators, supply approximately 1200 kv.-a. each in corrective capacity.

The question is sometimes raised regarding the use of synchronous converters for power-factor correction. Machines of this class as normally designed are not adapted for this service, by reason of the limits from heating both in the armature and field windings. Owing to the difficulties of obtaining satisfactory commutation under load conditions with the flux distribution that results from the presence of the reactive current in the armature, designing machines with sufficient heating capacity for this service is looked upon with disfavor.

To emphasize the desirability, particularly from the standpoint of the generator, of maintaining system power factors, at, say, 80 per cent. or higher, the curves, Fig. 7, have been worked up for a normally designed generator rated at 6000 kv.-a. at 500 r.p.m., showing the variations in performances with varying power factors. These curves show, basing all performances on 80 per cent. power factor as the normal condition and assuming constant kilovolt-ampere output, that if the power factor drops to 60 per cent., the exciting amperes become 111 per cent., the exciting voltage 116 per cent., and the field temperatures rise 126 per cent. of those quantities at 80 per cent. power factor. On the basis of reducing the output to maintain the same field heating, a change from 80 per cent. power factor to 60 per cent. reduced the generator rating to 86 per cent. of the original output.

Special Joint Committee Hearing on Administration Water-Power Bill

The Special Joint Water-Power Committee of the House of Representatives held another hearing on the Administration bill on Apr. 15, with Sir Adam Beck, chairman of the Hydro-Electric Power Commission of Ontario, as the speaker. Sir Adam delivered an exhaustive analysis from his own point of view of conditions relating to water-power development in the Dominion, and the sale of hydro-electric energy in Ontario, as compared with what he knows of conditions in the United States. He made a strong plea for monopoly in public utilities and presented figures tending to show that under government control in Toronto the rate for electricity is about half the rate at Buffalo, and made other comparisons between rates in the United States and in Ontario.

Secretaries Baker and Houston To Be Heard

The hearings before the joint committee will not be closed until the committee has heard Secretary Baker of the War Department, Secretary Houston of the Agricultural Department, and any members of Congress who desire to be heard. The framing of the final bill will therefore be delayed in the committee.

Sir Adam Beck has been identified with water-power matters in Ontario "since 1903 or 1905." He traced the growth of legislation in Canada, saying franchises were originally granted to generate power at Niagara Falls on the Canadian side, as follows: To the Canadian-Niagara Power Co., 100,000 hp.; to the Electric Development Co., 125,000 hp., and to the Ontario Power Co., 180,000 hp. He said the object of the boards of trade, merchants' associations, etc., in Ontario was to make this power available generally to the people of the district, and because of the great advance in the art of transmitting energy at high voltage, economically, to great distances, a desire was created in manufacturing districts to have this power available for them. Sir Adam pointed out that Ontario has no known coal fields at this time, and that one of the power difficulties there is the necessity for long transportation, and a duty on coal. That difficulty has long continued.

In 1902, he said, various civic bodies appointed a committee to confer with the legislature on steps to enable municipalities to undertake the generation of electricity. The legislature had two years previously refused the city of Toronto a franchise to develop power, and instead had granted such a franchise to the Electric Development Co., which had affiliated with it the Toronto Electric Light Co. and the Toronto Street Railway Company.

Finally, the legislature passed an act allowing municipalities to borrow money on their own account for power and light development, and a commission was appointed to investigate, which, after eighteen months' work, practically said that power could be delivered at cost; but the practical difficulty of raising money was encountered, and further rights for development were granted to the Electric Development Company.

Sir Adam then told of changes in the government following elections and of the passage of the present acts and amendments. He said:

> We have power to acquire by purchase or otherwise, on any terms, and hold shares in any incorporated company carrying on the business of developing, supplying and transmitting electrical energy. We have power to appropriate the land, waters, water privileges or water powers or works, machinery and plants or portions thereof of any person owning or operating under lease or otherwise or operating or using water-power privileges or transmitting electrical power or energy in Ontario which in the opinion of the commission should be purchased, acquired, leased, taken, expropriated and developed or used by the commission for the purposes of the act. Now, that is pretty drastic, but it is all subject to arbitration.

At the present time the Ontario Commission has contracts with 225 municipalities. They pay all interest charges at 4 per cent. and a sinking fund of 1.8 per cent., which retires in thirty years. They pay all charges of depreciation, operation, administration, etc. The chairman continued:

> We operate at the present time twelve systems. They will become interconnecting eventually and form one great trunk system. In this way we are attaining the object of the whole scheme; namely, that there should be one control only. . . . We want to create a real monopoly because we believe all these service undertakings should be a monopoly. There is little satisfaction in having competition in a telephone system, or a telegraph system, or even a railway system, and certainly not in an electric system in any community. The obnoxious poles and wires, the great dual cost of everything, and the great dual investment that results because of the diversity created by these various corporations covering the same field are undesirable from every standpoint.

The Power Situation at Niagara

As to the Niagara situation, Sir Adam said the principle laid down by the International Waterways Commission is that there should be an equal division of water for power purposes on all international streams, and pointed out that there is now pending an application that the United States Government shall confer with the Dominion authorities regarding a proposal to allot another 10,000 ft. per sec. to each government. This, he pointed out, is advanced as a war measure, and will be justified even though the most efficient use is not made of the water. Sir Adam said he believes that if this measure is carried through it will not be canceled after the war and will stimulate production after peace comes. He presented figures to show that the total power now being generated on both sides of Niagara is 653,500 hp. Of this amount 265,000 hp. is generated in the United States, which also receives 110,000 hp. exported from the Canadian side, making a total of 375,000 hp. available in the United States. This amounts to 40 per cent. more for the United States than for Canada, although the latter country generates 100,000 hp. more than the United States.

There is no intention on the part of either the Canadian government or the commission to interfere with the present export arrangement, even though Canada is now short 100,000 hp. In order to permit a continuance of the export, Canada has arranged to do away with all sign lighting, window lighting and other uses of energy which in some quarters have been characterized as less essential. The power generated by the province of Ontario has reduced coal consumption between 5,000,000 and 6,000,000 tons per annum. Motive power has been saved, use of cars has been saved, and duty on coal has been saved. The estimated potential horsepower of hydro-electric energy in Canada is about 50,000,000, and in Ontario alone about 5,000,000 or 6,000,000, with but 700,000 developed. At the beginning of the commission's work, in 1910, only 750 hp. was being delivered to the twelve municipalities interested. The commission has acquired up to date about 86 corporations, through friendly negotiations, and without resorting to the drastic powers given to it under the act.

Coal-Car Situation Serious

The United States Fuel Administration is gravely concerned over the serious falling off in coal production which has become apparent since the beginning of the coal year on Apr. 1. Despite the many measures adopted by the Fuel Administration to increase production and facilitate distribution, the supply of bituminous coal of the country fell off 1,500,000 tons, or 14 per cent., during the week ended Apr. 6, as compared with the preceding week, according to the reports of the Geological Survey.

Some part of this loss was due to failure of mine labor on Apr. 1, Mitchel Day, the anniversary of the enactment of the eight-hour law. With the exception of two weeks during the hardest weather of the winter, the daily bituminous production was lowered during the week ending Apr. 6 more than at any time since the Fuel Administration was organized.

A large part of this falling off in production, however, is due to the continued lack of transportation service as evidenced by the shortage of cars placed at the mine to be loaded. This is due to the general pressure of war traffic on the railroads. Car shortage reports for the week ended Apr. 6 are not yet available, but for the week ended Mar. 30 the mines throughout the country showed an average loss in production due to car shortage of 23.3 per cent.

In the fields of Illinois, Indiana and Ohio the average loss due to car shortage was 22.6 per cent. In one of these, the northern and central Ohio field, the loss was 34.2 per cent. In the Pennsylvania fields the loss in production due to car shortage averaged 32.4 per cent. In the New River and Winding Gulf and Pocahontas fields, which supply the low-volatile coal vitally needed by the Navy and the merchant marine for bunker purposes, loss in production due to car shortage was 24.4 per cent. In the high-volatile fields of southern West Virginia and the Fairmont, the average loss in production due to car shortage was 50.3 per cent.; the southern high-volatile fields lost 41.6 per cent. and the Fairmont fields 59.1 per cent. Cumberland Piedmont field showed a loss of production of 15.6 per cent., and the mine fields in Kentucky, the Southern Appalachian fields and the southwestern Virginia fields an average loss of 29.7 per cent., due to car shortage.

On the other hand, in the Alabama, Kansas, Missouri, Oklahoma, Arkansas, Iowa, Rocky Mountain and Pacific Coast fields the car service was within 5 per cent. of normal. Except for Alabama the bulk of the output of these mines goes into domestic consumption and is utilized west of the Mississippi River. It does not enter into the transportation problem in the congested Eastern territory.

This continued shortage of cars at the mines in the fields supplying the Eastern industrial territory has had the effect of keeping mine labor idle for days at a time, and in some of the fields has cut the working time to one or two days a week. Under these conditions the mine workers, unable to maintain themselves and their families on their curtailed pay, have been tempted by the steady employment offered by the war industries in the manufacturing centers.

The Fuel Administration is gravely apprehensive lest this condition result in the complete demoralization of the labor supply of the bituminous mining industry. Even a short continuance of these car-supply conditions will result in the forcing out of the mining fields the labor which the mining operators and the Fuel Administration may find it impossible to replace, even if the railroads are unable to offer a full car supply to the mines later in the summer. Reports to the Fuel Administration give evidence of unrest and dissatisfaction among the mine workers who throughout the past year have given patriotic service, even when it meant a personal sacrifice.

Among the causes of disturbance curtailing production is the unsettled situation regarding contracts for railroad fuel. This question is under consideration by the Railroad and Fuel Administrators and will be settled at the earliest moment possible.

The Fuel Administration is convinced that unless there is immediate and material improvement in car supply efficiency, the country faces the certainty of a serious shortage of bituminous coal.

The Fuel Administration will undertake to see that the preferred classes included in Preference List No. 1, of the Priority Committee of the War Industries Board are the first to receive their quota of the limited supply. This priorities list includes domestic consumers of coal.

Patriotic coöperation by the domestic users of the country in the effort of the Fuel Administration to secure the "early ordering" of next winter's domestic coal supply has filled up many of the retail dealers of the country with orders that cannot be delivered for weeks or possibly months. These consumers will be given their proper preference, however, and their coal will be delivered just as rapidly as the railroads can move it. The uncertain state of the supply makes it imperative that every domestic consumer should have his order in the hands of his dealer at the earliest possible moment.

New Publications

GRAPHICS. By H. W. Spangler. Published by John Wiley & Sons, New York City. Cloth, 6 x 9¼ in., 95 pages. Price, $1.25.

The book contains the substance of lectures on the subject of graphics given to the students in mechanical, electrical and chemical engineering at the University of Pennsylvania. They are intended to cover only fundamental principles, and those familiar with the subject will recognize that the methods of treatment used by the many writers have been utilized in their preparation. Many of the short-cuts in common use are not referred to in the text as the time allotted to this work is limited, and while such short-cuts are of special value in special work, they are readily grasped by one who has a fundamental knowledge of the entire subject.

The author states that it is intended that the book shall be used as a reference work. It should serve this purpose well.

REFRIGERATION By Milton W. Arrowood. Published by the American Technical Society, Chicago. Flexible leather, 7 x 4¾ in., 272 pages exclusive of the index.

This little book has the appearance of a handbook, but cannot be said to be a handbook of the usual type as the author has endeavored to treat the subject more from a practical than from a theoretical viewpoint, giving only enough physical theory on the problems of heat measurements, pressure, etc., to make the text understandable. On the whole the illustrations in the book, which are mostly line drawings, are well done. Good descriptions of the various systems of refrigeration are given, and the descriptions of commercial machines are very good. In that part of the book treating of ice making the author deals with the various systems, with storing and selling ice and with ice-plant insulation. About 38 to 40 pages are devoted to cold storage. Pages 143 to 160 are devoted to methods of refrigeration, proportions between the parts of a refrigerating plant, testing, operation and management of the plant.

COAL: THE RESOURCE AND ITS FULL UTILIZATION

The Division of Mineral Technology, United States National Museum (Smithsonian Institution), is producing a set of papers entitled "The Mineral Industries of the United States, six in all, the aim being to present a constructive analysis of the fuel situation in the United States. This series is known as Bulletin 102, Parts 1 to 6 inclusive. Those already issued are: Part 1, Coal Products: An Object Lesson in Resource Administration. Part 2, Fertilizers: An Interpretation of the Situation in the United States. Part 3, Sulphur: An Example of Industrial Independence. Part 4 (just out). Coal: The Resource and Its Full Utilization. Part 5 (in preparation). Power: Its Significance and Needs. Part 6 (in preparation). Petroleum: A Resource Interpretation.

Part 4, just to hand, is a splendid, dispassionate analysis of the fuel situation, pointing out in nontechnical language the things that are necessary and must ultimately be done to correct the inherent deficiencies in the utilization of coal. In spite of ample supplies in the ground, coal inadequately meets its obligations: first, because of the competitive manner in which it is mined; second, the unnecessary extent to which it is transported; and, third, the improper way in which it is used. The Bulletin contains 26 pages, 6 by 9 in., and is worthy of careful reading.

Personals

O. S. Maple, formerly purchasing assistant of the United States Shipping Board, Emergency Fleet Corporation at Washington, D. C., has recently been appointed assistant purchasing officer of that corporation.

W. Nelson Smith, who was for some years electric traction engineer with Westinghouse Church Kerr & Co., and more recently efficiency engineer of the American Agricultural Chemical Co., is at present with Sydney E. Junkins & Co., engineers and constructors, of Vancouver, B. C.

Charles Philip Coleman, who has been vice-president of the Worthington Pump and Machinery Corporation since May, 1916, and prior to that was receiver of the International Steam Pump Co. and associate companies, which have since been reorganized into the present corporation, has been elected president.

J. C. Rockwell has been promoted from manager of the light and power department to general manager of the Manila (P. I.) Electric Railroad and Light Co. He joined the operating organization of the J. G. White Management Corporation, New York City, in 1911, and was assigned to the Manila Electric Railroad and Light Co. as manager of the light and power department. He has been on a visit to the United States and is now returning to Manila.

Engineering Affairs

Plant Engineers' Club—The entertainment committee made a trip to Providence on Wednesday, Apr. 24, to visit the Narragansett Electric Light Co., and to inspect the new 50,000-kw. generator set and the new Leblanc condenser. In the evening, at the Boston City Club, they discussed the question of proper fire and police protection in large manufacturing plants.

The New York Chapter of the American Association of Engineers concluded its first year's activity with a dinner and speeches at the Grand Hotel on the evening of Apr. 20. The speakers were R. H. Vanderbrook, retiring chairman of the chapter; S. J. Stone, chairman-elect; I. L. Birner, secretary; William Serton, H. H. Bubor, W. J. Ash, C. H. Nordell, A. C. Davis and J. F. Jones.

The Combined Associations of Greater New York N. A. S. E., through the New York State Educational Committee announce a lecture by Mr. Forde, of the Westinghouse company, on the evening of May 4, on "Steam Turbines and Auxiliary Apparatus," at Ionic Hall, Terrace Garden, 155 E. 58th St., New York City. Through the courtesy of Charles S. Bavier a visit will be made to the power plant of the Metropolitan Insurance Co. Building, Madison Ave. and 23rd St., New York, on the evening of May 2.

Boston Engineers' Dinner—The ninth annual dinner of the Boston Society of Civil Engineers, American Society of Mechanical Engineers and the American Institute of Electrical Engineers will be held at the Boston City Club, Tuesday, Apr. 30, 6:15 p.m. James W. Rollins will be toastmaster. So far, two speakers have been engaged. W. H. Blood, Jr., of the American International Shipbuilding Corporation, will speak on "The Greatest Shipyard in the World"; Alfred D. Flynn, secretary of the Engineering Council, will speak on "The Engineering Council, Its Progress and Changes." Other speakers likely will follow. The presidents of the societies represented, also representatives of the Army and Navy, have been invited as guests.

Miscellaneous News

Thrift-Stamp Day Advanced to Monday, May 6—It has been decided to advance Thrift-Stamp Day in the United States from May 1 to May 6, in order to avoid conflicting with the wind-up of the Liberty Loan drive, which ends May 4. So remember your new slogan is "Sixth of May, Thrift-Stamp Day in the U. S. A." This gives you more time to put it over bigger and better than ever. Keep hustling.

The Johns-Pratt Co., of Hartford, Conn., has appointed Lucas Blanco & Co., as its agents for Porto Rico, Virgin Islands, Dominican Republic and the Republic of Haiti.

Trade Catalogs

Centrifugal Pumps—The Wheeler Condenser and Engineering Co., Carteret, N. J. Bulletin 108-B. Pp. 8 x 10½ in. Shows the latest Wheeler turbine-driven geared centrifugal pumps, for either series or parallel operation; and special slow-speed engine-driven pumps.

NEW CONSTRUCTION

Proposed Work

Mass., Canton—The Springdale Finishing Co. will build a 1 story, 50x50 ft. engine house on Pine St., Springdale. A. H. Wright, 53 State St., Boston, Arch. Noted Apr. 16.

N. Y., Buffalo—The Donner Steel Co., 475 Abbott Rd., has had plans prepared for the erection of a 2 story, brick and steel boiler shop, locker, etc. Estimated cost, $20,614.

N. Y., Elmira—The Elmira Water, Light and Power Co. has been authorized by the Public Service Commission to build an electric transmission line from here to Montour Falls. F. H. Hill, Supt.

N. Y., Newark—The Board of Managers, State Custodial Asylum, plans to build additions and alterations to its heating plant; new equipment will be installed. Estimated cost, $35,000.

N. Y., Niagara Falls—The Board of Directors of the Niagara Falls Gas and Electric Co., 306 Niagara St., will soon receive bids for a gas plant to be erected on the Riverway. Gas making machinery including gas holders, etc., will be installed. Estimated cost, $500,000. W. L. Adams, 311 Falls St., Engr.

N. Y., Ogdensburg—The New Jersey Zinc Co. plans to rebuild its power house which was recently destroyed by fire. Loss about $300,000.

N. Y., Thiells—The Board of Managers, Letchworth Village, plans to build an additional central heating plant and install equipment. Estimated cost, $225,000.

N. Y., Utica—The Board of Managers, Utica State Hospital Comm., Albany, plans to install new boilers and make all necessary changes in the central heating plant at Utica State Hospital. Estimated cost, $130,000.

N. J., Cape May—The Vulcan Heat, Light and Power Co. plans to improve the equipment in its plant. H. H. Ross, Supt.

N. J., Newark—The Board of Freeholders, Essex Co., will receive bids until May 1 for alterations and additions to the heating, piping and mechanical equipment in the power house and throughout the various buildings of the Essex County Hospital, Overbrook. Runyon & Carey, 845 Broad St., Newark, Consult Engr. Noted June 28.

Penn., Bristol—The Town Council plans to change the motive power of the pumping station from steam to electricity.

Penn., Harwood Mines—The Philadelphia Electric Co., 10th and Chestnut Sts., Philadelphia, and the Electric Bond and Share Co., 71 Bway., New York City, plans to extend their electric power stations here and build 3 new ones.

Penn., Mauch Chunk—The Town Council has plans under consideration for improvements to its electric street lighting system.

Penn., Philadelphia—The Bureau of Yards and Docks, Navy Dept., Wash., will soon award the contract for the installation of 3 electrically operated traveling cranes for its air craft factory. Estimated cost, $56,000.

Penn., Reading—The Reading Ry. plans to build a power house on Tulip and Somerset Sts. S. T. Wagner, Reading Terminal, Philadelphia, Ch. Engr.

Ala., Headland—City voted $10,000 bonds to improve its electric lighting and waterworks systems.

Ala., Mobile—The Moran Shipbuilding Co. plans to enlarge its electric lighting plant and shipyards.

Ky., Mount Olivet—The Mount Olivet Electric Light and Power Co. plans to install either a storage battery or a small engine and a 10 kw., 220 volt, d. c. generator. J. H. Kain, Owner.

Ohio, Massillon—Massillon Electric and Gas Co. plans to rebuild its electric lighting plant which was recently damaged by fire. Loss about $250,000. F. L. O'Connor, Supt.

Ill., Chicago—The Illinois Central plans to build a $60,000 power house at its Burnside plant, 95th and Cottage Grove Ave. A. S. Baldwin, 35 East 11th Place, Ch. Engr.

Ill., Springfield—The St. Johns Hospital plans to install wiring and a heating system. Estimated cost, $3000 and $10,000 respectively. Helme & Helme, Springfield, Arch.

Ill., Springfield—The Springfield Light, Heat and Power Co. has applied to the State Utility Commission for permission to issue $100,000 in bonds; the proceeds will be used to extend its mains and purchase boilers and mechancial equipment. J. E. Dalby, 1157 North 3rd St., Supt.

Wis., Butternut—The Butternut Electric Light and Power Co. plans to install an additional 3 wire generator. with 15 kw. capaciy. W. J. Schultz, Mgr.

Wis., Milwaukee—The C. Ansted Leather Co., 560 Commerce St., plans to install an additional 150 kw. steam generating unit and 16 electric motors of an aggregate of 165 hp. Estimated cost $10,000.

Minn., Tommald—City has plans under consideration for the installation of an electric lighting system.

Kan., Peru—City plans to install an electric lighting plant here.

Kan., Winchester—The Automatic Electric Light Co. of Kansas City plans to install an electric lighting and power plant near here.

S. D., Bradley—The Dakota Northern Power Co. plans to build a steam plant and install a 300 kw. reciprocating unit. E. H. Lewis, Secy.

N. D., Fargo—City plans to install an electric lighting plant at the water works station. J. J. Jordan, City Engr.

Mo., Kansas City—The Kenwanee Boiler Co., 1420 McGee St., is in the market for a hand power or electrically driven traveling crane on tracks, similar to locomotive type, with 20,000 lb. capacity.

Tex., Calvert—The Calvert Water, Ice and Electric Co. plans to extend its electric power transmission line from here to Bremond. A. E. Stoltz, Mgr.

Tex., Clyde—R. Cook plans to build an electric lighting and power plant here.

Tex., Dallas—Smith & Whitney, 1405 Southwestern Life Bldg., is in the market for a 300 kw., 250 volt. WX 2 or 3 wire direct current generating set, cross compound, non condensing, non releasing Corliss type engine; an engine type generator without engine but for direct connection to engine of above type would be considered.

Tex., Nixon—The Nixon Electric Light and Power Co., recently incorporated with $12,000 capital stock, plans to build an electric light and power plant. J. F. Wood, interested.

Ala., Birmingham—The Tennessee Coal, Iron and R.R. Co. plans to improve its power station at the Ensley blast furnaces. Equipment including a 7500 kw. turbo generator. J. H. Kain, Owner.

Va., Williamsburg—The Williamsburg Power Co. has increased its capital stock from $25,000 to $150,000; the proceeds will be used to build additions and make improvements to its plant.

Tex., Pleasanton—The City Council has taken over the plant of the Pleasant Ice and Electric Co. and plans to install additional equipment and machinery. F. H. Burmeister, Mgr.

Tex., Round Rock—S. E. Bergstron, Kerns, plans to build an electric lighting and power plant here.

Okla., Cyril—City plans to build an electric lighting plant.

N. M., Clovis—City voted $25,000 bonds for electrical improvements.

Wash., Chehalis—O. E. Anderson and associates plan to build a power plant here.

Wash., Mondovi—The Washington Water Power Co. plans to install electric lights here.

Wash., Snohomish—The Snohomish Dairy Products Co. plans to install an electric motor in several departments.

Que., Montreal—Lamontague, Ind., 338 Notre Dame St., W., plans to build a power house. Estimated cost, $10,000. E. Laurie & Co., 243 Bleury St., Engr.

Ont., Cobalt—The Mining Corporation of Canada, Ltd., plans to install electric driven pumps on scows and will purchase motors, pumps, pipe, etc.

Sask., Arcola—The Arcola Light and Power Co. plans to change its system from single phase 110 volts, to 3 phase 2300 volts. G. F. Robert, Mgr.

Ont., Haileybury—The Dickson Creek Mining Co. plans to install electrically driven drills at its property on Dickson Creek.

CONTRACTS AWARDED

N. H., Goffstown—The Manchester Traction, Light and Power Co. is building a new power house and a dam in the Greggs Falls district here. E. Farrell, Engr.

Mass., Boston—The Bureau of Yards & Docks, Navy Dept., Wash., has awarded the contract for the erection of a new power plant at the Navy Yard, here. Estimated cost, $35,000.

N. J., Trenton—The Crescent Insulated Wire and Cable Co., Olden and Taylor Sts., has awarded the contract for a 3 story, 83 x 103 ft. factory, to the Barclay White Co., 1713 Sansom St. Estimated cost, $100,000. The company will install an entire steam heating system, electric elevator and electric lighting system.

Penn., Philadelphia—The G. W. Smith Co., 49th and Botanic Ave., has awarded the contract for the erection of an addition to its boiler house, to J. N. Gill and Co., Otis Bldg. Estimated cost, $35,000.

Penn., Philadelphia—The L. Walther Manufacturing Co., Torresdale Ave. and N St., has awarded the contract for the erection of an addition to its boiler plant, to G. H. Thirsk, 1919 West Berks St. Estimated cost, $21,000.

Ky., Nortonville—The Norton Coal Mining Co. has awarded the contract for the erection of an addition to its central power plant, to the Ruby Lumber Co., Madisonville.

Neb., Lincoln—The State Board of Control has awarded the contract for a power house to be erected at the penitentiary, to R. C. Stake. Estimated cost, $13,380.

Okla., Park Hill—C. Sells, Commissioner of Indian Affairs, Wash., D. C., has awarded the contract for the installation of a steam heating plant in the Cherokee Training School, to the Bradley Heating Co., St. Louis, Mo.

Ore., Helix—The Helix Mill Co. has awarded the contract for wiring for the installation of electric light power plant in the mill, to J. Vaughn, 206 East Cort St., Pendleton.

Calif., Fresno—The San Joaquin Light and Power Co. is building a new substation east of the Standard reservoir farm. New equipment including four 1000 kva. transformers, switches, etc., will be installed. A. G. Wishon, Gen. Mgr.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular Apr. 25, 1918	Individual Apr. 25, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	1.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—3.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular Apr. 25, 1918	Individual Apr. 25, 1918
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Apr. 25, 1918	One Yr. Ago	Apr. 25, 1918	One Year Ago
Pea	$3.45	$2.80	$4.35	$3.70
Barley	2.15	1.50	2.40	1.75
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties April 25, 1918	Mt. Olive & Staunton April 25, 1918	Standard April 25, 1918
6-in. lump	$2.65-3.00	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg	2.65-2.80	2.35-2.50	2.25-2.40

No. 1 nut	2.65-3.00	2.65-2.80	2.65-2.80
2-in. screen	2.15-2.40	2.15-2.40	2.15-2.40
No. 5 washed	2.15-2.30	2.15-2.30	2.15-2.30

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cababa.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, MAY 7, 1918 No. 19

What Real Effort Can Do

A POORLY-DRESSED young man stood outside a massive brick building listening to the dull humming sound that emerged from the inside, and watched for the approach of a big blue touring car that he knew would soon pause to let out a big, keen-eyed individual, the general superintendent of one of the largest central stations in the Middle West. The young man, whom we will call Mr. Lane, approached the superintendent and asked for a "job." "Got a trade?" asked the superintendent. "No, sir," replied Lane, "but I'd like a chance. I am interested in electricity." Lane's sincerity of manner appealed to the superintendent and he was told to come inside.

Once inside, Lane was stunned at the magnitude of the place. Powerful electric generators were driven by massive steam engines and turbines; an overhead electric crane was lifting a huge casting off the floor to be put in its place in the assembling of a new unit; engineers and oilers were moving about, and up and down the machinery on the galleries, which were connected by narrow gangways with brass guard rails. There were whistles and bells, and colored lights and what not, and Lane's fondest hope was to help handle these monsters whose constant motion fascinated him.

"Well, young man," said the superintendent, "what do you want to do?" Lane replied: "I am not particular about what I do; what I want is an opportunity to learn and get ahead." "Any education?" asked the superintendent. "I only completed the eighth grade in public school," replied Lane; "I have been working on a farm for my brother." "Humph!" exploded the superintendent; "not very much experience behind you, young man, but I'll put you to work." So Lane was put on the payroll at one dollar per day and was told to report for work the next day.

Lane eagerly waited for his first day among those big, noisy machines. When he appeared at the office, he was immediately put to work—washing windows. Dirty, greasy, grimy windows they were, too, but he did a thorough job; he cleaned every window in that station, wiped the glazed brickwork and cleaned up some of the out-of-the-way corners around the station. He also found time to clean the office furniture and the glasswork about the superintendent's office every day. He kept his eyes and ears open and used his work as a stepping stone to something better. He was soon put in the repair gang, where he handled big sledgehammers and wrenches ten hours a day. He kept plugging along, developing his acquaintance with the operating crews. He got to know Jansen, chief operator on the switchboard, pretty well. Jansen had worked his way up, and he admired Lane and his bulldog tenacity. As time went on Lane got pretty well acquainted with the power-house gang. He worked in the "gang" on repairs for over two years, and became a first-class handy man; he got to know every pipe line in the place, and he knew just how to go about it to start overhauling the machines. By this time he decided to drop the mechanical end of the gang and specialize on electricity, so he asked for a chance on the switchboard. He was enrolled as one of the switchboard crew and put to work cleaning generators, wiping switchboards and oil switches. One day each week he was helper to the regular switchboard operator—here is where he began to develop. When one of the substation operators quit, Lane got his place. After a year in the substation he was put back in the power house as regular board operator. He now started to do things; he recommended little improvements that began to show the superintendent his capacity. After a couple of years on the board as operator he was a well-trained employee.

About this time Jansen, the chief operator, resigned to accept a better position elsewhere. He recommended Lane for his place, and Lane got to be chief operator. Here is where his troubles began, and he was called on to use extraordinary judgment in the discharge of his duties. Some of the other operators had longed to get Jansen's berth, and it did not increase Lane's prestige with his men when they saw him go around them in promotion. There was a reason for his promotion, but they couldn't or didn't see it. He studied hard, worked hard and did not know the latest cabaret singer or how many ingredients there were in a good cocktail; but he did know the value of work. He put every ounce of energy that he possessed into his work, and his love of impartiality and equal justice soon won over his subordinates. He knew the value of concentrated effort and self-reliance. He was chief operator for three years, then became load dispatcher. Here he again showed his master mind by countless new methods of load manipulation, especially during peak loads. From this he went into electric repairs, then to electric construction. He became foreman of electric construction with 100 men under him. He had personal charge of the construction of two new stations, in the electrical end, and since then has been promoted to electrical superintendent of one of the largest electrical syndicates in America. He has a thoroughly organized department of 250 men under him, a corps of assistants who have been trained just as he was, from the bottom round of the ladder. Discipline is one of his mottoes, and his department shows it.

Fearless, loyal and true as steel, severely strict, yet patient when essential—Lane has rounded into a grand old man. Loved by one and all who come in contact with him, a born leader among men, he owes his success to his keen realization of the value of hard and conscientious labor. Not a college man, but a natural-born thinker, abnormally developed through his keen insight and experience as he traveled through the college of life. He is today an acknowledged authority in his profession, has patent rights on some complicated electrical devices and is filling one of the really large electrical positions of today. He never sat down and wished for success—he got busy, and commandeered it.

Central-Station Heating in Detroit

By J. H. WALKER
Superintendent of Central Heating, Detroit Edison Company

Features of the live-steam heating plants and system of the Detroit Edison Co. Reasons why live steam replaced exhaust steam for district heating.

CENTRAL heating as a public utility was originally conceived upon the idea of utilizing exhaust steam from electric generating units. The majority of the systems in operation today, excepting the numerous hot-water installations, use exhaust steam as the distributing medium and by combining the heating and electrical systems secure high thermal efficiency. In some instances, however, it has proved more desirable from a broader economic standpoint to distribute for heating live steam at a relatively high pressure instead of exhaust steam and to operate independently condensing generating plants. Such was the case in Detroit, and it is the purpose of this article to describe some of the features of the live-steam heating plants and systems of the Detroit Edison Co. and to discuss the reasons that led to the abandonment of exhaust-steam heating in favor of the live-steam method. The present heating system in Detroit is a combination of the systems of the Central Heating Co. and the Murphy Power Co., which were taken over by the Edison company in 1910 and 1914, respectively. The district served is about two miles long and one-half mile wide and includes the central business district and what was formerly an exclusive residential district, although now gradually changing to an apartment-house and business section. The total length of mains is about 22 miles, and approximately 1700 customers are served, the buildings heated being shown in Fig. 1. The amount of radiation connected aggregates about 2,600,000 sq.ft. There are four boiler plants having in all 17,470 rated boiler horsepower. In the year 1917 a total of 1,769,000,000 lb. of steam was sold. The steam is used principally for heating buildings, but a considerable amount is used for cooking and water-heating purposes. Only a small quantity is sold for power uses, and this service is being gradually discontinued.

FIG. 1. CENTRAL HEATING SYSTEM, DETROIT EDISON CO.

The pressure carried on one section of the distribution mains constituting about one-third of the total system is approximately 30 lb., while the pressure on the remaining sections, which were originally operated as exhaust-steam systems, is now from 6 to 12 lb. and is necessarily increased from year to year as the load increases. It is expected that eventually the entire system will be operated at a pressure of 30 lb. or higher. The pressure is limited at present by the low allowable pressure of the expansion fittings and in some cases by the lack of reducing valves in the consumers' buildings. All new construction is built for 125 lb. nominal working pressure. In the part of the system on which the pressure is nominally 30 lb., only 10 lb. is guaranteed at the consumer's service valve, this minimum pressure having been found to be entirely adequate for cooking purposes. Thus there is available, under extreme conditions, a pressure gradient throughout the system of 20 lb. This adds considerably to the flexibility of operation and to the capacity of the distribution mains. The boiler pressure carried in the plants is 130 lb., and the steam is delivered direct to the heating system through reducing valves. In comparing the relative advantages of exhaust-steam and live-steam operation, the obvious advantage of the former method is the ther-

Farmer St. Plant

FIG. 2. HEATING PLANTS OF THE DETROIT EDISON COMPANY

mal economy made possible by utilizing the heat in the exhaust steam instead of throwing it away, as is done to a great extent in a condensing plant. Or, looking at the matter from the opposite viewpoint, to carry the steam through electric generating units before delivering it to the heating system makes possible the generating of electrical energy at a low fuel cost. One great disadvantage in distributing exhaust steam, however, is the size of the distribution mains required. If turbines are installed, exhausting into the heating system at a relatively low pressure, the pressure differential throughout the system is, of necessity, very small, and this, together with the higher specific volume of the steam, requires the use of much larger pipes than is the case when steam at a higher pressure is used.

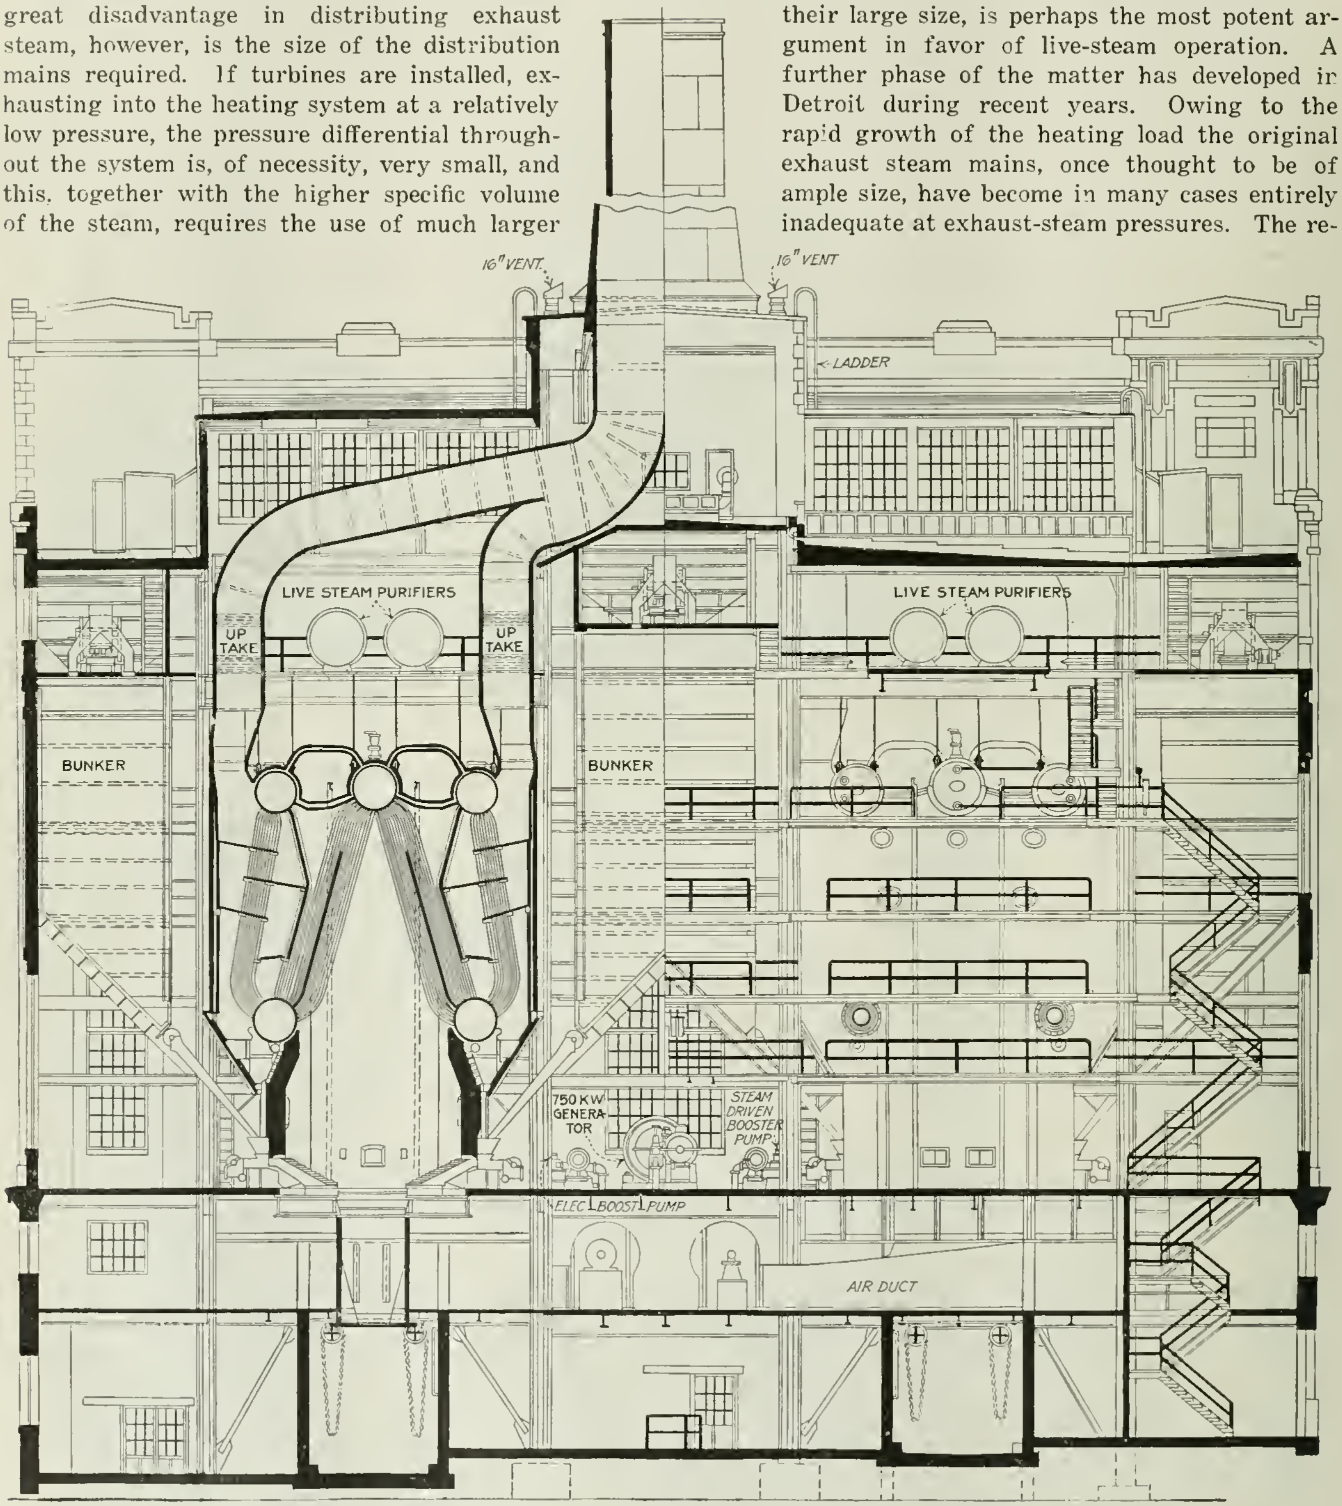

FIG. 3. SECTIONAL ELEVATION OF THE CONGRESS STREET HEATING PLANT

A good example of this condition exists in Detroit. The largest pipes in the portion of the system operated at 30 lb. pressure are 12 and 10 in., while the system formerly operated by the Murphy Power Co. and laid out as an exhaust-steam system, has several hundred feet of 20- and 16-in. pipe and the pipes throughout are considerably larger than in the live-steam system. The two systems cover nearly equal areas and serve about equal amounts of radiation.

The much greater investment in underground lines required in an exhaust-steam system, due to their large size, is perhaps the most potent argument in favor of live-steam operation. A further phase of the matter has developed in Detroit during recent years. Owing to the rapid growth of the heating load the original exhaust steam mains, once thought to be of ample size, have become in many cases entirely inadequate at exhaust-steam pressures. The recent change to live-steam operation with a higher pressure gradient has increased the capacity of the system. Had this not been done, it would have been necessary to replace the large trunk mains with still larger ones.

The installation of high-pressure feeders, as will be described later, has also been of inestimable value in the transmission of steam, and their use would be impossible with complete exhaust-steam operation.

Another equally important point against exhaust-steam operation concerns the investment in plant equipment. The amount of generating capacity that could be installed in the heating plants might aggregate, at the outside, 5000 kw. This capacity would not affect in the slightest degree the actual size of the company's main generating stations, in which the unit most recently added is of 45,000 kw. capacity. The investment represented by the units in the heating plants, together with the building space occupied, would therefore represent additional investment, the annual charges for which, because of the poor annual load factor of the units, would be relatively high per kilowatt-hour generated. Nor would the investment in transmission lines from the main generating stations be in any way reduced. These factors, together with the cost of the necessary attendance per kilowatt-hour—much greater than that in the main generating stations—would also tend to offset the saving due to the lower fuel cost of the current generated.

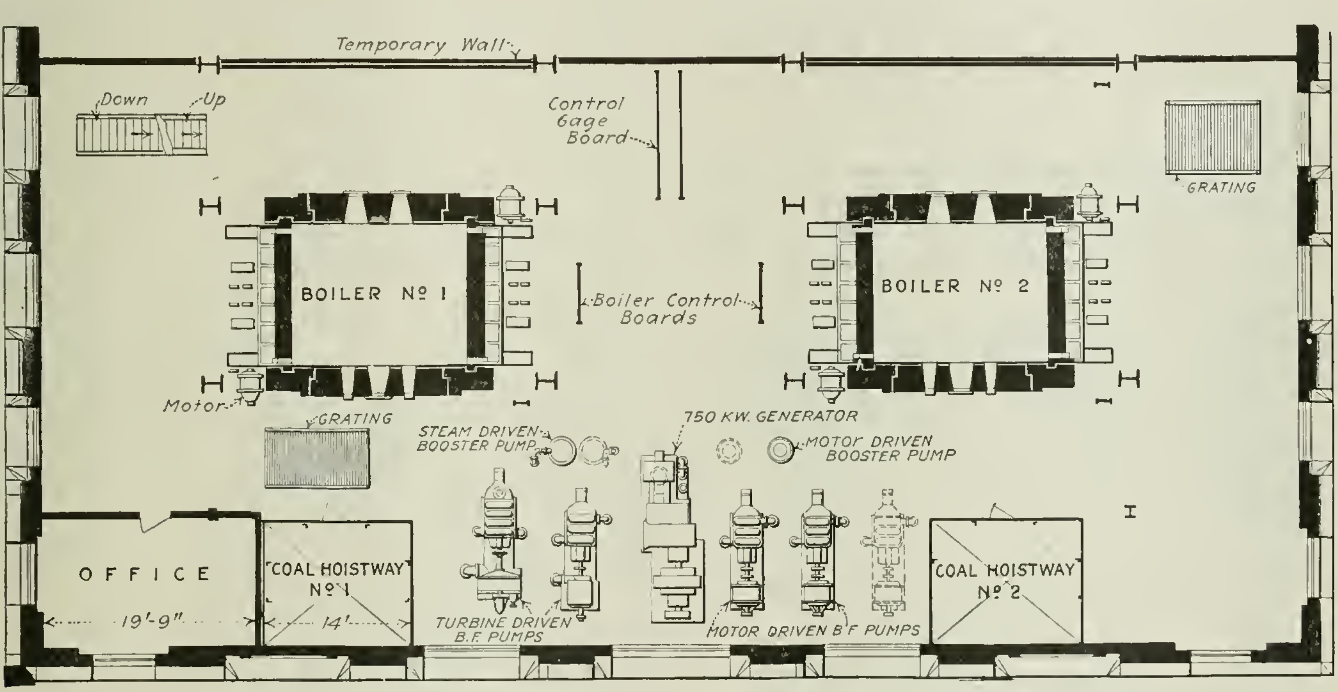

FIG. 4. PLAN OF PRESENT SECTION OF CONGRESS STREET STATION

The four heating plants are shown in Fig. 2. They are equipped, for the most part, with Stirling boilers and underfeed stokers. The newest is the Congress Street plant, the first boiler unit of which was put into service in December, 1917. This plant is designed to contain, eventually, 10,000 rated boiler horsepower, consisting of four 1300-hp. units and two of 2400 hp., capable of being operated at 200 per cent. of rating continuously. The present section contains the first two of the smaller boilers. They are Stirling boilers of the "W" type, quite similar in cross-section to the large Delray and Connors Creek boilers. They are fired from both sides with Taylor stokers.

In the design of the plant an effort was made to select and arrange the equipment so that the size of the operating crew would be reduced to a minimum. To this end the various auxiliary machines are located in so far as possible so as to be within easy reach of the operating engineer, and the operation of the plant is controlled almost entirely from the firing floor. Fig. 3 is a cross-section of the plant, and Fig. 4 is a plan view of the present section.

In any steam-power plant an appreciable economy can be gained if the power for driving the auxiliaries is obtained from a prime mover whose exhaust is utilized in heating the feed water. Ordinarily, this is accomplished by the use of steam-driven auxiliaries. The advantages of motor drive, however, as regards speed regulation, low maintenance cost and little attendance are well recognized. In the Congress Street plant the advantages of both kinds of drive will be secured by means of a house-service turbo-generator whose exhaust will be utilized in heating the feed water and which will supply current to the motor-driven auxiliaries. The size of the unit, 750 kw., is such that a good annual load factor will be secured, when the plant is completed, with all the exhaust used in heating the feed water. A considerable amount of current in excess of the requirements of the auxiliaries will be generated and will be fed to the Edison distribution system. The load on the generator will be adjusted as required, so as to furnish the proper amount of exhaust steam. By this means a large quantity of electrical energy will be generated at a low unit cost, without the disadvantages of an exhaust-steam distribution system. The size of the unit is not such that any additional attendance will be required, nor will it occupy any considerable building space.

The turbo-generator and the boiler-feed pumps are located on the firing floor. Both motor-driven and turbine-driven pumps are provided, the former being the ones ordinarily in use and the steam-driven pumps being reserved for emergency service. No injectors are provided.

Like the others, the Congress Street plant is dependent for its water supply upon the city mains. To insure against interruption of the supply in case of failure of the city water pressure, "booster" pumps are provided to augment, when necessary, the pressure in the mains, sufficiently to raise the water to the boiler-feed pumps. The booster pumps are in the subbasement and are driven through vertical shafts by vertical turbines and motors on the firing floor. As long as the city mains are full of water, even though the pressure be low, the plant will not be without water.

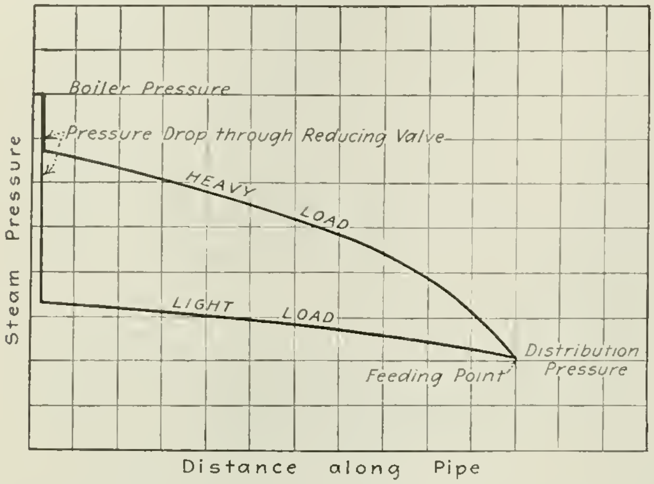

FIG. 5. PRESSURE DROP IN FEEDER

Storage tanks of a capacity sufficient to supply the plant for about one hour when operating at maximum capacity are provided as an additional safeguard.

As very little of the condensation is returned to the plant from consumers' buildings, purification of the large amount of raw water was considered advisable. The Detroit River water is not a bad boiler water, containing but seven grains of total solids per gallon.

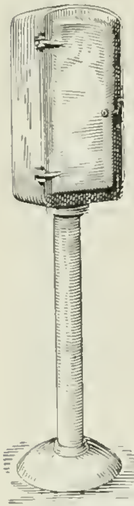

FIG 6

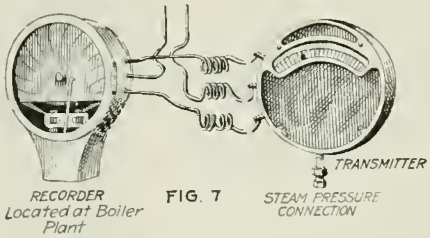

FIG. 7

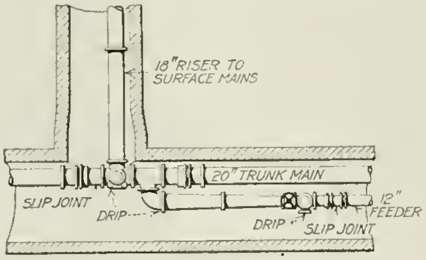

FIG. 8

FIG. 6. BOX FOR TRANSMITTER. FIG. 7. LONG-DISTANCE GAGE. FIG. 8. ENLARGEMENT OF FEEDER AT FEEDING POINT

Live-steam purifiers, two to each boiler, are employed to precipitate the scale-forming materials. Careful research in one of the older plants has demonstrated that there is a small amount of additional precipitation of calcium sulphate in the boiler itself due to the concentrating action that takes place. Though relatively small in amount, the scale deposited on the tubes has been sufficient, at high evaporation rates and under certain extreme conditions, to cause overheating and failure of the tubes. In all the plants sodium carbonate is now injected into the boiler-feed water in carefully graduated amounts just sufficient to insure the complete conversion of the scale-forming sulphate to the nonscale-forming carbonate which is removed in the blowoff.

Since the plants are situated, perforce, at some distance from the railroads, it is necessary to haul the coal to them by motor truck. The fuel is received at two coaling stations located on railroad sidings and is there crushed and raised to overhead bunkers, from which it is taken by the trucks. Each truck carries a bucket of six tons capacity and pulls a trailer similarly loaded.

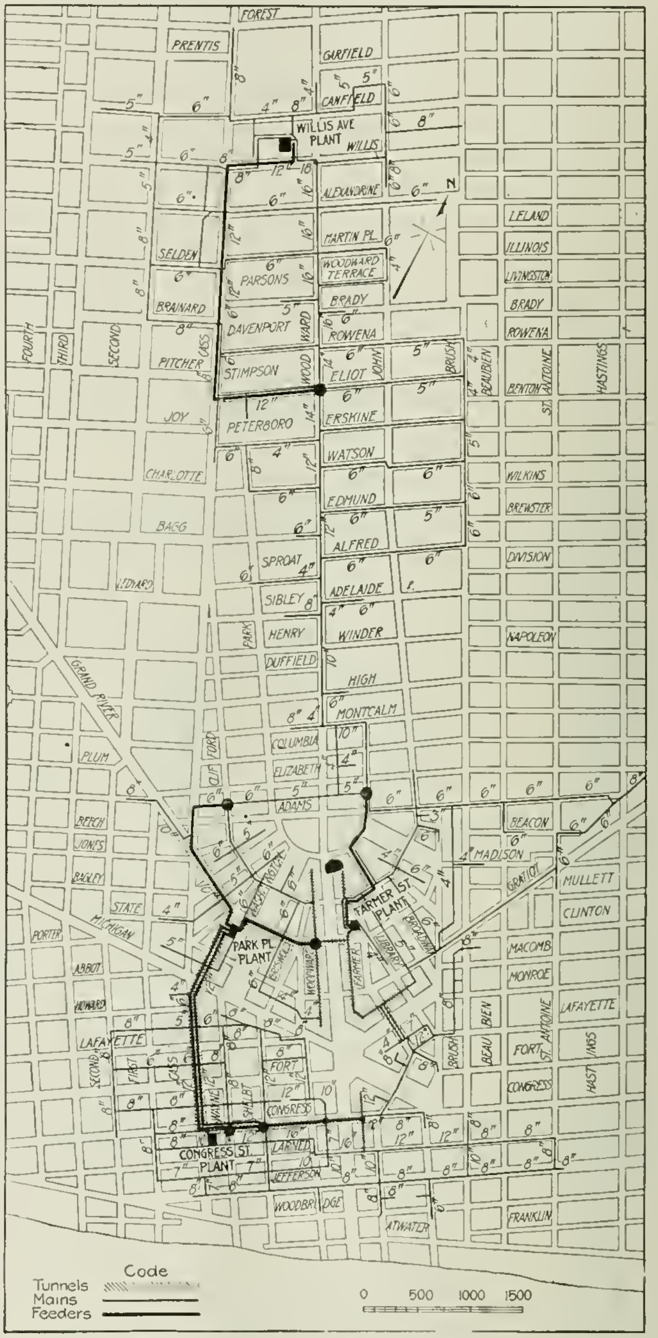

FIG. 9 STEAM DISTRIBUTION SYSTEM, SHOWING FEEDERS

At the Congress Street plant the buckets are hoisted by an overhead traveling crane and are emptied into hoppers from which belt conveyors distribute the coal to the overhead bunkers.

Elimination of all ash-conveying machinery is made possible at Congress Street, by the placing of the boilers at a sufficient height to permit the ash hoppers beneath them to be emptied directly into the trucks that haul the ashes away.

One rather unusual feature of the Detroit system is the method employed for distributing the steam. Although the first mains were installed but fifteen years ago and the majority of them much more recently, the rapid growth of the city and the connecting of large buildings at remote parts of the system have rendered the mains entirely inadequate. To meet this condition the original pipes are treated as distribution mains, from which the service connections are made, and feeders are installed to transmit the steam from the plants to certain points in the distribution network. No buildings whatever are served from these feeders, their function being simply to transmit steam to the various centers of load. The scheme may be compared to that used in electrical distribution in which feeders, radiating from the generating station, carry current with a large voltage drop to various points in the network of mains.

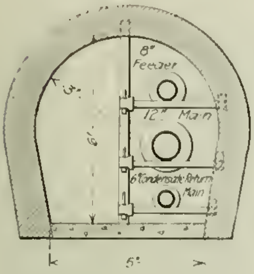

FIG. 10. SIX-FOOT TUNNEL

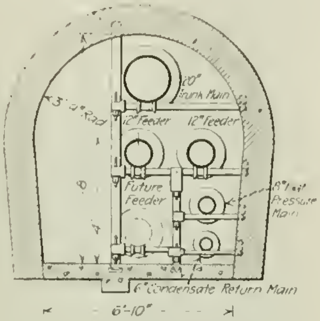

FIG 11. EIGHT-FOOT TUNNEL

In selecting the pipe sizes for such feeders, advantage is taken of the large differential between boiler pressure and distribution pressure to reduce the size of the pipes by allowing the pressure drop to take place largely along the pipe itself. In fact, under maximum conditions the entire pressure drop could be allowed to take place in the pipe instead of in the reducing valve. This greatly increases the capacity of the feeder and allows the use of relatively small pipes. The steam is delivered from the boiler header to each feeder through a reducing valve, and the pressure carried is adjusted so as to maintain the required distribution pressure at the remote end of the feeder. The pressure drop in such a feeder is illustrated graphically in Fig. 5. For a light load the pressure drop takes place largely in the reducing valve, while for a heavy load the greater portion of the total drop occurs in the pipe itself.

A record of the pressure existing at the feeding point is furnished to the engineer at the plant by means of an electrically operated long-distance recording gage, and the pressure on the feeder is adjusted as required so as to maintain the proper pressure at the feeding point. A gage of this type is shown in Fig. 7. The street box in which the transmitter is placed is shown in Fig. 6.

The velocity of the steam in feeders of this kind becomes extremely high under conditions of heavy load, reaching, in some actual cases, 75,000 ft. per min. Owing to the large quantities of steam flowing, the radiation loss per pound of steam is practically negligible and the expansion is nearly adiabatic, the steam reaching the feeding point in a superheated condition. It is possibly due to this fact that, in spite of the high velocities attained, there has been no noticeable erosion of the pipe.

To reconvert some of the velocity head of the steam into static head, the velocity of flow is reduced at the end of the feeder by a gradual enlargement of the pipe. A typical connection of this sort is shown in Fig. 8.

There are, in all, six of these high-velocity feeders in service, as shown in Fig. 9. Each is equipped with a long-distance gage and is operated in the manner described.

The heating system includes, in all, about 10,000 ft. of walking tunnels. Tunnels are almost a necessity where several pipes are to be installed, particularly in the congested districts where the blockading of streets for the construction or maintenance of the pipes would be a burden upon the public. The tunnels are all of brick with concrete floors and are built in the horseshoe shape, as in Fig. 10. They are from 30 to 40 ft. below the surface. The greater part of the tunnels is about 6 ft. high by 6 ft. wide, and they contain from one to three steam pipes and a return line. One section is 8 ft. high by 8 ft. wide and contains room for several pipes, as illustrated in Fig. 11. Under the rather favorable soil conditions existing in Detroit, waterproofing of the tunnels, except in a few locations, is unnecessary.

About two-thirds of the total length of surface mains is installed in wood casing and the remainder in a concrete conduit of the form shown in Fig. 12. The latter type of construction has proved very satisfactory and is being used on all new work. It is made of common materials, is simple to install and is undoubtedly long-lived. Though not entirely waterproof, it is sufficiently so for ordinary conditions.

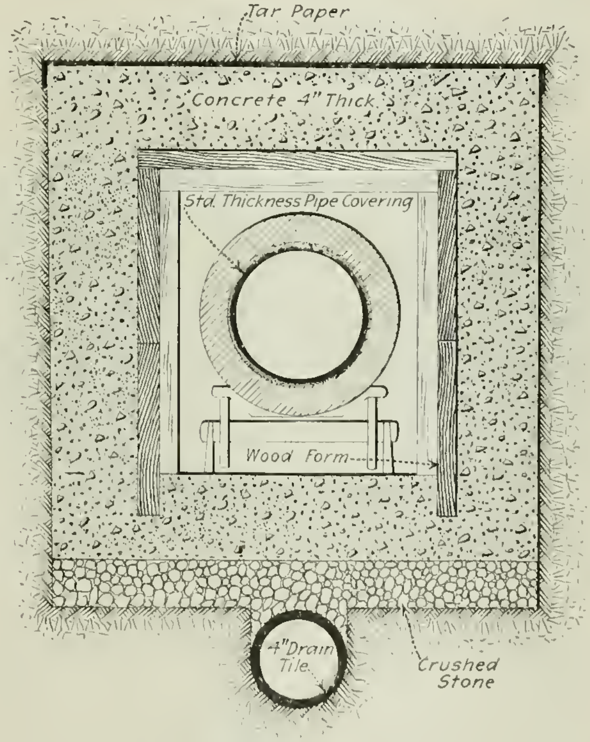

FIG. 12. CONCRETE CONDUIT FOR UNDERGROUND PIPES

A test was made in 1913-14 to determine the amount of condensation formed in the distribution mains. In a part of the system operated at that time at a pressure of about 5 lb., the condensation per hour per square foot of external pipe surface was 0.0511 lb. For a section operated at 25 lb. pressure, the corresponding figure was 0.0593 lb. Both sections were laid partly in wood casing and partly in the concrete construction.

Expansion is taken care of by slip joints in all recent construction. The older lines have joints of the copper-diaphragm type.

Consumers' installations are of no standard design, any well-constructed system being acceptable to the company, subject to certain regulations. New installations are provided with reducing valves. Consumers are urged to install economizing coils to utilize the latent heat in the condensation. These are constructed in the form of an indirect radiator or as a preheater for the domestic water. The steam is sold entirely on a condensation-meter basis.

Luitwieler Single-Plunger Double Acting Pump

Almost any engineer would be skeptical if he were told that a single-cylinder double-acting pump could be designed to operate as high as 100 r.p.m. and deliver a steady stream of water. He knows that a simplex pump delivers its water in a pulsating stream, the water coming from the discharge at its lowest velocity and volume when the piston is reversing its stroke, and he also knows that when a pump is run at a high speed it will pound.

Readers of *Power* will remember that nearly five years ago a description of a Luitwieler double-acting triplex pump was published (p. 53, July 8, 1913). A similar pump is illustrated in Fig. 1. It differs in that it has a single cylinder and plunger. The mechanism, however, is the same; that is, the plunger derives its motion through a cam that is secured to the driven shaft. Rollers carried by the crossheads work against this cam from opposite sides, and the cam is so shaped as to cause the plunger to produce an even flow of water at the discharge throughout the cycle. This pump is manufactured by The Luitwieler Pumping System Company of New York, Rochester, N. Y.

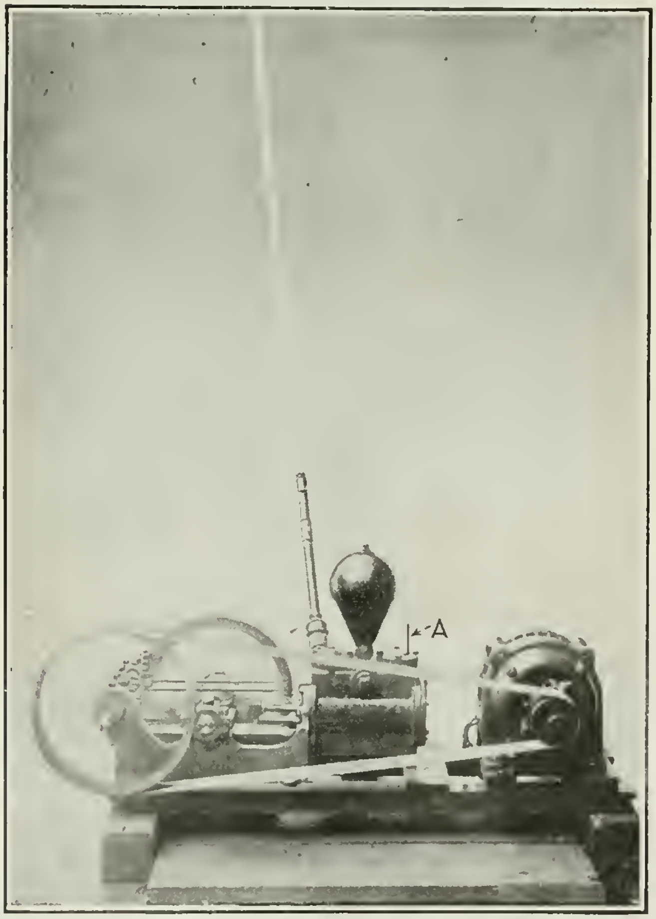

FIG. 1. SINGLE-PLUNGER DOUBLE-ACTING PUMP

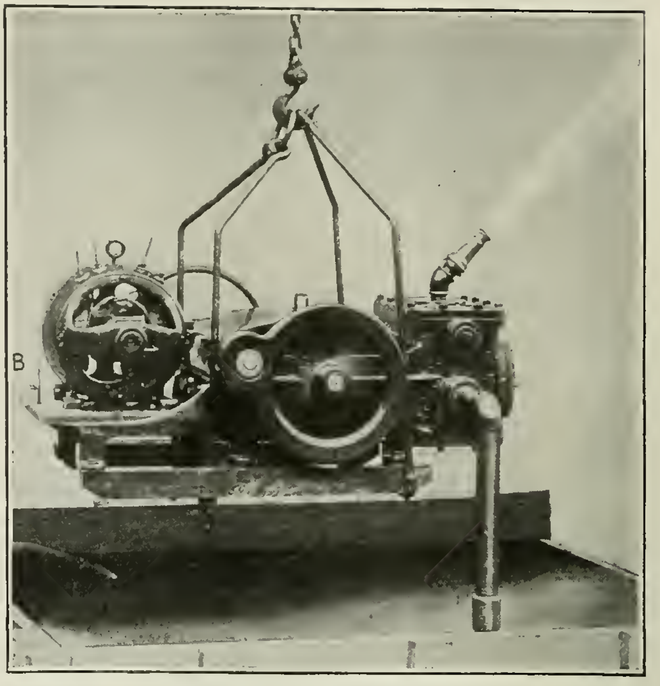

FIG. 2. TRIPLE-PLUNGER PUMP OPERATING ON SUSPENDED PLATFORM

An idea of the steadiness of the discharge stream can be obtained from Fig. 1, where a cam-driven, single-cylinder, double-acting pump is shown in operation. The bore is 5 in., the stroke 5 in. and the revolutions 48 per minute; discharge pressure, 70 lb. The pump and motor are mounted on skids which rest on 6-in. blocking spaced 5 ft. apart. A 4-in. wire nail is shown standing on end at the top plate at *A*, thus indicating the absence of vibration. This pump has been operated at a speed of 100 r.p.m. Water is taken from the reservoir below the pump.

One can hardly conceive of a reciprocating pump being operated without being bolted to a solidly constructed foundation, because of the jar, and yet this has been done with the Luitwieler design, as is shown in Fig. 2, where the pump is suspended from a chain above a tank of water. This pump, which is of the triple-plunger design with 3 x 3-in. cylinders, is shown delivering 82 gal. of water per minute with a pressure that throws a stream 100 ft. through a 1⅛-in. nozzle. The motor speed is 1600 r.p.m., and the pump is running at 150 r.p.m. It will be noticed that there is no air chamber on the water end. The weight of the unit is 1020 lb. The absence of vibration is indicated by the 5-in. wire spike shown standing on end at *B*.

Before you spend money for yourself, think whether your country can afford to have you spend that money. Every dollar saved helps twice, first when you refrain from spending it for nonessentials, and again, when you lend it to the Nation.

The Electrical Study Course—Compound-Wound Generators

It is shown that, owing to the resistance of the armature windings, the voltage at the terminals of a shunt generator will decrease as the current increases, and this variation can be compensated for by the addition of a series winding on the polepieces, making a compound-wound machine.

IN FIG. 3 is a diagram of a shunt generator or motor. In this all that is indicated is the circuits; the armature is indicated as a segmental ring and the field winding as a spiral. However, it will be seen that the field circuit in Fig. 3 is in parallel with the armature, as in Fig. 1. In Fig. 4 the field winding is connected in series with the armature as in Fig. 2, making one circuit through the machine in either case. The diagrams, Figs. 3 and 4, provide a convenient means of representing the circuit through electrical machinery, and will be used many times in future lessons.

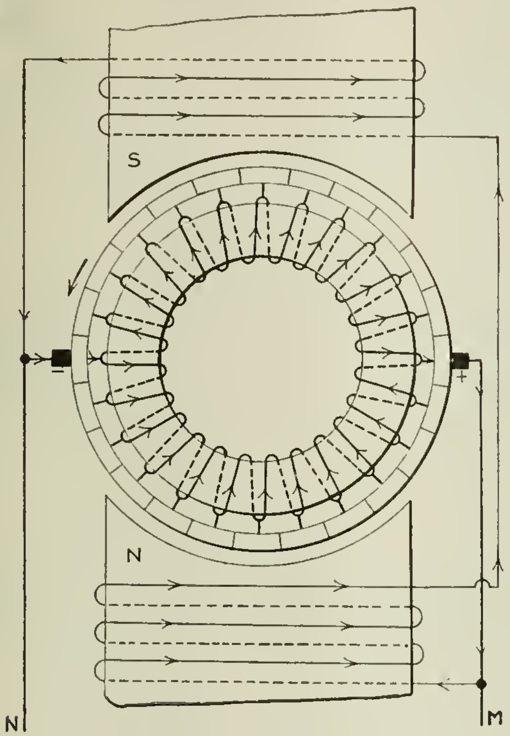

FIG. 1. SHUNT-CONNECTED GENERATOR

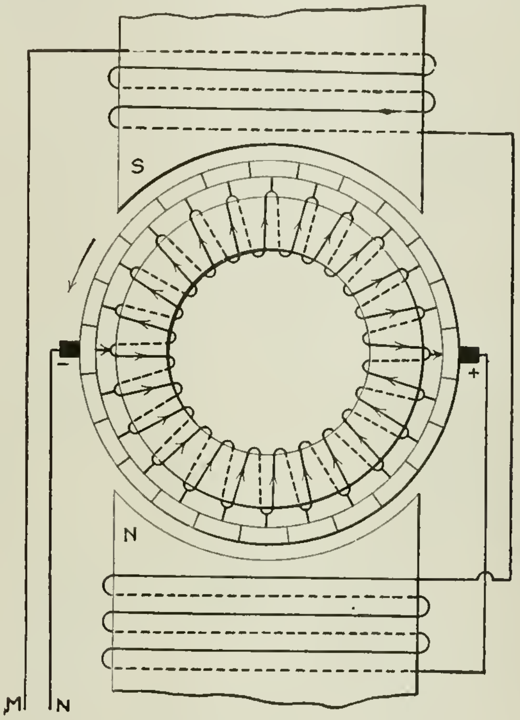

FIG. 2 SERIES-CONNECTED GENERATOR

In Fig. 5 the field coils are shown excited from a source separate from the armature, so that any variation in the voltage at the armature terminals will not affect the strength of the magnetic field. Assume that the armature has 0.23 ohm resistance and generates 115 volts on open circuit, as in Fig. 3 Now, if a resistance of $R' = 5$ ohms is connected across the terminals of the generator, as in Fig. 5, the total resistance of the circuit will be R equals that of the armature and external circuit in series, or $R = r + R' = 0.23 + 5 = 5.23$ ohms, and the current that will flow in the circuit is

$$I = \frac{E}{R} = \frac{115}{5.23} = 22 \text{ amperes.}$$

As has been explained in previous lessons, part of the voltage produced in the armature will be used up in the armature winding to cause the current to flow through this section of the circuit. This voltage e is equal to the resistance of the armature times the current; that is, $e = rI = 0.23 \times 22 = 5.06$ volts. From this we see that when 22 amperes is flowing in the circuit, there is 5.06 volts drop in the armature winding. Hence the available voltage at the armature terminals is $Ea = E - e = 115 - 5.06 = 109.94$ volts, as shown.

Consider what would be the effect of connecting a second resistance of 5 ohms across the generator terminals, as shown in Fig. 6. The joint resistance of r' and r'' is R' equals one-half that of r, or $R' = 5 \div 2 = 2.5$ ohms. Then the total resistance of the circuit is the joint resistance of the external circuit and that of the armature winding, from which $R = R' + r. = 2.5 \times 0.23 = 2.73$ ohms, and the current $I = \frac{E}{R} = \frac{115}{2.73} = 42$ amperes approximately. To cause the current to flow through the armature will require a voltage $e = rI = 0.23 \times 42 = 9.66$ volts. This will leave a voltage of $Ea = E - e = 115 - 9.66 = 105.34$ volts available at the armature terminals, as indicated.

From what we have seen in Figs 5 and 6, it is evident that as the load is increased on a shunt generator the voltage at the armature terminals decreases. The voltage generated by the armature would also, to a certain extent, decrease if the field coils are connected to the brushes, as shown in Fig. 3. For the reason that as the voltage decreases across the armature terminals the current will be decreased in the field coils, consequently the number of lines of force will be reduced. In Fig. 5 with a resistance of 5 ohms connected across the armature 22 amperes flowed through the circuit, while in

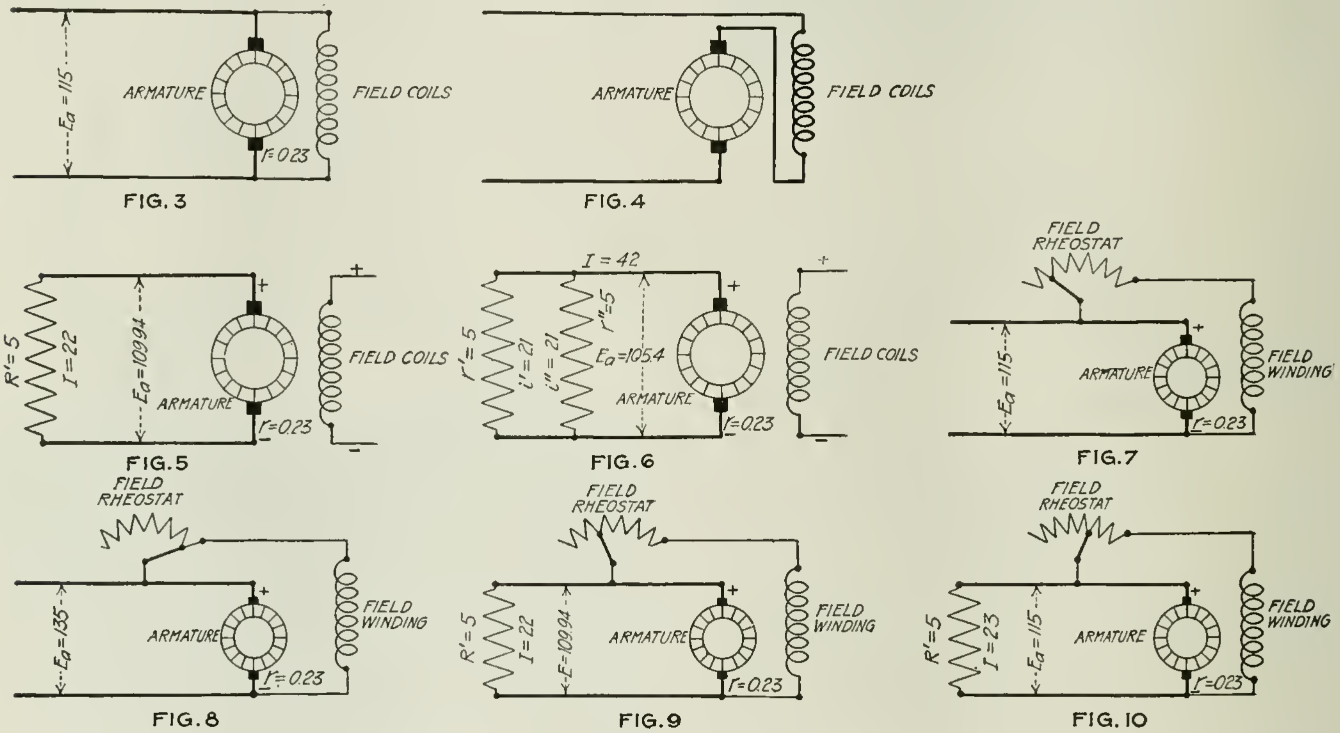
Fig. 6, where two resistances of the same value are connected in parallel, only 21 amperes is sent through each resistance, showing that as the load increases on a shunt generator, unless some means is taken to maintain the voltage constant, the current will decrease in each circuit as more load is connected to the generator.

One way of maintaining the voltage practically constant would be to design the generator for about 20 per cent. over voltage and connect a rheostat in series with the field winding, as in Fig. 7, to reduce the field current to a value where normal voltage would be generated at no load; then, as the voltage falls off because of an increase in load, sections of the rheostat can be cut out of circuit so that the field current will increase to a value that will cause the generator to produce sufficient pressure to maintain the voltage at the armature terminals constant.

For example, with the field rheostat cut out of circuit, as in Fig. 8, assume that the machine will generate 135 volts, and with part of the rheostat cut in series with the field windings, as shown in Fig. 7, the voltage decreases to 115. Then, neglecting the effect of the decrease in voltage at the armature terminals, due to increase of load, on the field winding and connecting a 5-ohm resistance across the armature terminals, as in Fig. 9, the current in the circuit will be approximately 22 amperes and the voltage will drop to 109.94, as in Fig. 5. Now to bring the voltage back to normal, some of the field rheostat can be cut out, as in Fig. 10. This will increase the current in the field coils and in turn increase the field strength, so that the armature conductors will be cutting a greater number of lines of force and producing a great voltage; as is shown in the figure, the voltage has been increased to normal, or 115.

With 115 volts available at the armature terminals, the current in the external circuit is $I = \frac{E}{R'} = \frac{115}{5} = 23$ amperes, instead of 22 as in Fig. 9, and the volts drop in the armature is $e = rI = 0.23 \times 23 = 5.29$ volts. Therefore, for the armature to maintain 115 volts at its terminals with a 23-ampere load, it will not only have to generate the 115 volts available at its terminals, but also 5.29 volts to cause the current to flow through the resistance of the windings, or a total of $E = Ea + e = 115 + 5.29 = 120.29$ volts.

After the voltage had been adjusted to 115 at the armature terminals with a load of 23 amperes, if the load was taken off and the field rheostat not changed, the voltage would increase to 120.29 volts, or the total of that generated in the armature. Although, in Fig. 10, only 115 volts is available at the armature terminals, nevertheless, the machine is generating 120.29 volts; 5.29 volts is used up in the armature winding. As soon as the load is taken off, there is no current flowing through the winding to use up the 5.29 volts and it becomes available at the brushes. To bring the volts back to normal again it will be necessary to cut the resistance back into the field circuit, as in Fig. 9.



FIGS. 3 TO 10. DIAGRAMS OF SHUNT-CONNECTED AND SERIES-CONNECTED DIRECT-CURRENT MACHINES.

From what we have seen it is evident that if the load on a shunt generator is varying, the voltage will fluctuate according to the load. Of course, these fluctuations, if they do not occur too rapidly, can be taken care of by the operator adjusting the field rheostat. However, a better way of doing this, if possible, would be to incorporate some automatic means in the construction of the machine to maintain the voltage constant.

In the last lesson we found out that if the load is increased on a series-connected generator the voltage will increase, and decrease as the load decreases. Taking advantage of this fact provides a means of obtaining a close voltage regulation on direct-current generators. This is done by constructing what may be called a combination of a shunt and series machine, or, as it is known, a compound-wound generator. This connection is shown in Fig. 11. From this figure it will be seen that one field winding is connected in series with the armature, as in Fig. 2, and a second field winding connected across the armature, as in Fig. 1. The shunt-field winding provides the flux to generate about 110 to 115 per cent. normal voltage, the 10 or 15 per cent. excess volts being taken by the field rheostat. The series-field winding sets up the flux necessary to generate the additional voltage to compensate for the volts drop through the armature due to the load current and the resistance of the winding.

In Fig. 11, if the armature is revolved in the direction of the curved arrow, a voltage will be generated in the winding of a polarity as indicated and a current will flow through the shunt-field windings in the direction shown by the arrowheads. This voltage can be regulated to normal by adjusting the field rheostat, or as we will assume, to 115 volts. With no load on the machine no current is flowing through the series-field winding, although some machines are connected so that the shunt-field current flows through the series-field winding.

If a resistance is connected across terminals *M* and *N*, as in Fig. 12, of such value as will allow a current of, say, 25 amperes to flow, as indicated, this current passes through the series-field winding and will increase the number of lines of force entering and leaving the armature, consequently the voltage generated in the armature conductors will be increased. On the other hand, the current flowing through the armature will cause a certain voltage drop in the winding. Now if 5 volts is required to cause the current to flow through the armature winding, and the series-field amperes-turns cause the magnetic field to increase in value to where the armature will generate 120 volts, then the 5 additional volts will just compensate for the loss in the armature and the volts at the armature terminals will be maintained constant. If the current supplied to the load is increased to 50 amperes, then the current through the series-field winding will increase to 50 amperes, which in turn will increase the number of lines of force entering and leaving the armature and again cause the volts generated to build up and compensate for the drop in the armature, thus maintaining the e.m.f. constant at the brushes.

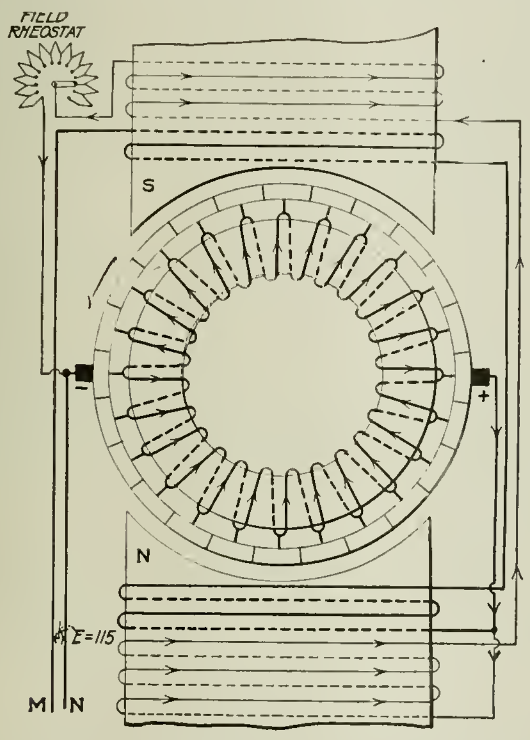


FIG. 11. COMPOUND-WOUND GENERATOR

The foregoing characteristic of the compound generator, which is nothing more nor less than a shunt generator, having in addition to the shunt winding, a series-field winding on its polepieces, to automatically maintain the voltage approximately constant at its terminals, has caused this type of machine, with certain modifications, to be adopted almost universally for generating direct current. Due to the iron in the polepieces becoming saturated, the lines of force do not increase in proportion to the ampere-turns on the field coils, thus making it impossible to design a compound generator that will maintain absolutely constant voltage from no load to full load. This subject will be discussed in the next lesson.

In problem 1 of the last lesson the copper cable was 1500 ft. long and made up of 37 wires 90 mils in diameter. The cross-section in circular mils of such a cable is equal to the cross-section of one strand times the number of strands. The cross-section of any round conductor in circular mils is equal diameter in mils squared, or in this case, $90 \times 90 = 8100$ cir. mils, and the cross-section of the cable is $8100 \times 37 = 299{,}700$, approximately 300,000 cir. mils. The conductor's resistance is

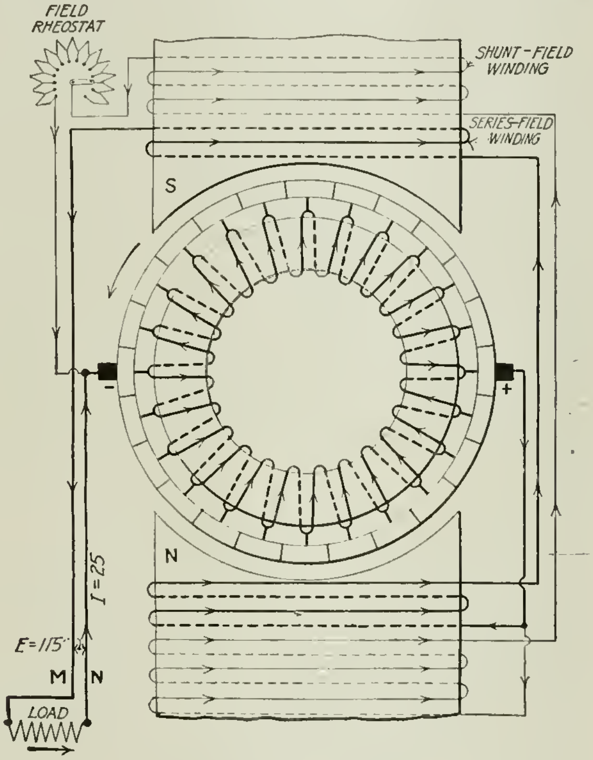

FIG. 12. COMPOUND GENERATOR CONNECTED TO LOAD

$$R = \frac{10.7}{cir.mils} = \frac{10.7 \times 1500}{300{,}000} = 0.0535\ ohm$$

In problem 2 the sizes of the conductors were required to transmit 350 kw. 75 ft. at 250 volts, with 0.5 per cent. drop. The current

$$I = \frac{kw. \times 1000}{E} = \frac{350 \times 1000}{250} = 1400\ amperes$$

Volts drop $E_d = E \times$ per cent. drop $\div 100 = 250 \times 0.5 \div 100 = 1.25$ volts. Then

$$Cir.mils = \frac{21.4DI}{E_d} = \frac{21.4 \times 75 \times 1400}{1.25} = 1{,}800{,}000$$

In transmitting 540 amperes over a circuit 425 ft. long, there is a drop of 16.4 volts in the line. How large is the conductor in cross-section? By how much would these conductors have to be increased in cross-section to transmit the same current with a drop of 10 volts?

Capitalization Value of Steam Leaks

BY R. VON FABRICE

Proper consideration of the capitalization values of thermal losses in power plants are too often neglected, although they are ever existent in the best of plants and represent staggering results. Leaky joints in steam lines are given consideration primarily because of the inherent dangers from explosions and destruction of life and equipment. The most numerous steam leaks are from stuffing-boxes, gaskets, leaky valves and free-blowing drips.

THE cost of generating steam represents the greater part of the ultimate cost of power production, and therefore its conservation is of prime importance in reducing the cost of the station output. Economical operation represents a value or bears a direct relation to capitalization, so that an outlay that results in the elimination of losses can be classified as an investment. Steam is the product of expenditures, and the cost is dependent upon the cost of fuel and water, the boiler efficiency and fixed charges made up of interest, taxes, insurance and depreciation. Therefore in a year a pound of steam saved per hour represents a considerable capitalization value to the station; or in other words, it would justify a certain expenditure in order to save the steam.

To ascertain the capitalization value of a pound of steam the cost of the steam must first be determined. Let

K = Cost of steam per 1000 lb. $= \frac{C}{E} + W$;

H = B.t.u. in one ton (2240 lb.) of coal $= 2240 \times h$;

h = B.t.u. in one pound of coal = 13,500 B.t.u.;

C = Cost of coal per ton (2240 lb.) = \$4;

L = Latent heat or B.t.u. required to evaporate one pound of water from and at 212 deg. F. = 970.4 B.t.u.;

F = Boiler efficiency = 70 per cent.;

e = Evaporation per pound of coal $= \frac{hF}{L}$;

$e = \frac{hF}{L} = \frac{13{,}500 \times 0.70}{970.4} = 9.74$ lb. of water evaporated per pound of coal;

E = Evaporation per ton of coal (2240 lb.) $= 2240 \times e = 2240 \times 9.74 = 21{,}818$ lb. of steam;

W = Cost of water (10c. per 1000 gal. = approximately 1.2c. per 1000 lb.);

$K = \frac{C}{E} + W = \frac{4}{21{,}818} + 1.2 = 19.53$c. per 1000 lb. of water from and at 212 deg. F.

Having determined the cost of the steam, in order to find the capitalization value the following conditions and assumptions must be kept in mind: (1) Assume a load factor of 100 per cent., that is, that the leak is a continuous drain on the station both day and night; (2) working year to be taken as 8640 hours or 360 days of 24 hours; (3) fixed charges, 17 per cent. of investment per year. The amount of steam lost by a leak is dependent upon the pressure of the steam and the size of the contracted orifice through which the steam escapes.

According to Napier's approximate formula for the outflow of steam through an orifice into the atmosphere

$$W = \frac{Pa}{70}$$

where

W = Weight of steam in pounds per second;
P = Absolute pressure of steam;
a = Contracted orifice (area in sq.in.);
70 = Constant.

Prof. C. H. Peabody conducted a series of tests to check the foregoing formula with pipes ¼ to 1¼ in. long, and the results were close to those obtainable with the Napierian approximate formula.

To illustrate the capitalization value of a steam leak, the following assumptions will be made: (1) Contracted area, or summation of leaks, 0.5 sq.in.; (2) boiler pressure, 250 lb. gage. Then $W = \frac{Pa}{70}$ (weight of steam per second) $= \frac{264.7 \times 0.5}{70} = 1.89$ lb., since

$P = 250 + 14.7 = 264.7$; $a = 0.5$ sq.in.; 70 = constant.

Then the loss of steam per hour is $1.89 \times 3600 = 6804$ lb. and for one year of 8640 hours is $8640 \times 6804 = 58{,}786{,}560$ lb.; and the cost per year at 19.53c. per 1000 lb. is $58{,}786.56 \times 19.53 = \$11{,}481$. The capitalization value of the steam lost can be determined as follows:

C = Capitalization value;
F = Fixed charges, assumed to = 17 per cent.;
K_2 = Total cost of steam lost.

Hence

$$C = \frac{K_2}{F} = \frac{11{,}481}{0.17} = \$67{,}535$$

The accompanying chart has been worked out, by means of which similar problems may be readily solved, and to illustrate its use the foregoing problem has been plotted on it. Beginning with the upper left-hand section, selecting the B.t.u. or heating value of the coal, say 13,500 B.t.u., follow vertically down to the diagonal line representing the over-all boiler efficiency (70 per cent.), thence horizontally to the right, crossing the vertical scale, showing the pounds of water evaporated per pound of coal, which in the problem given is 9.74 lb.; then continue to the upper right-hand section to the intersection of the curve giving the cost per ton (2240 lb.) of coal (\$4) and thence downward parallel with the vertical lines at the top of which is given the cost, in cents, of evaporating 1000 lb. of water from and at 212 deg. F. (in this case 18.33c.). Then continue downward, intersecting the diagonal line in the middle right-hand section, representing the cost of water (in this case 10c. per 1000 gal.), thence to the left to the vertical scale, where the cost of one pound of steam per hour per year (of 8640 hours) is given as \$1.69; then

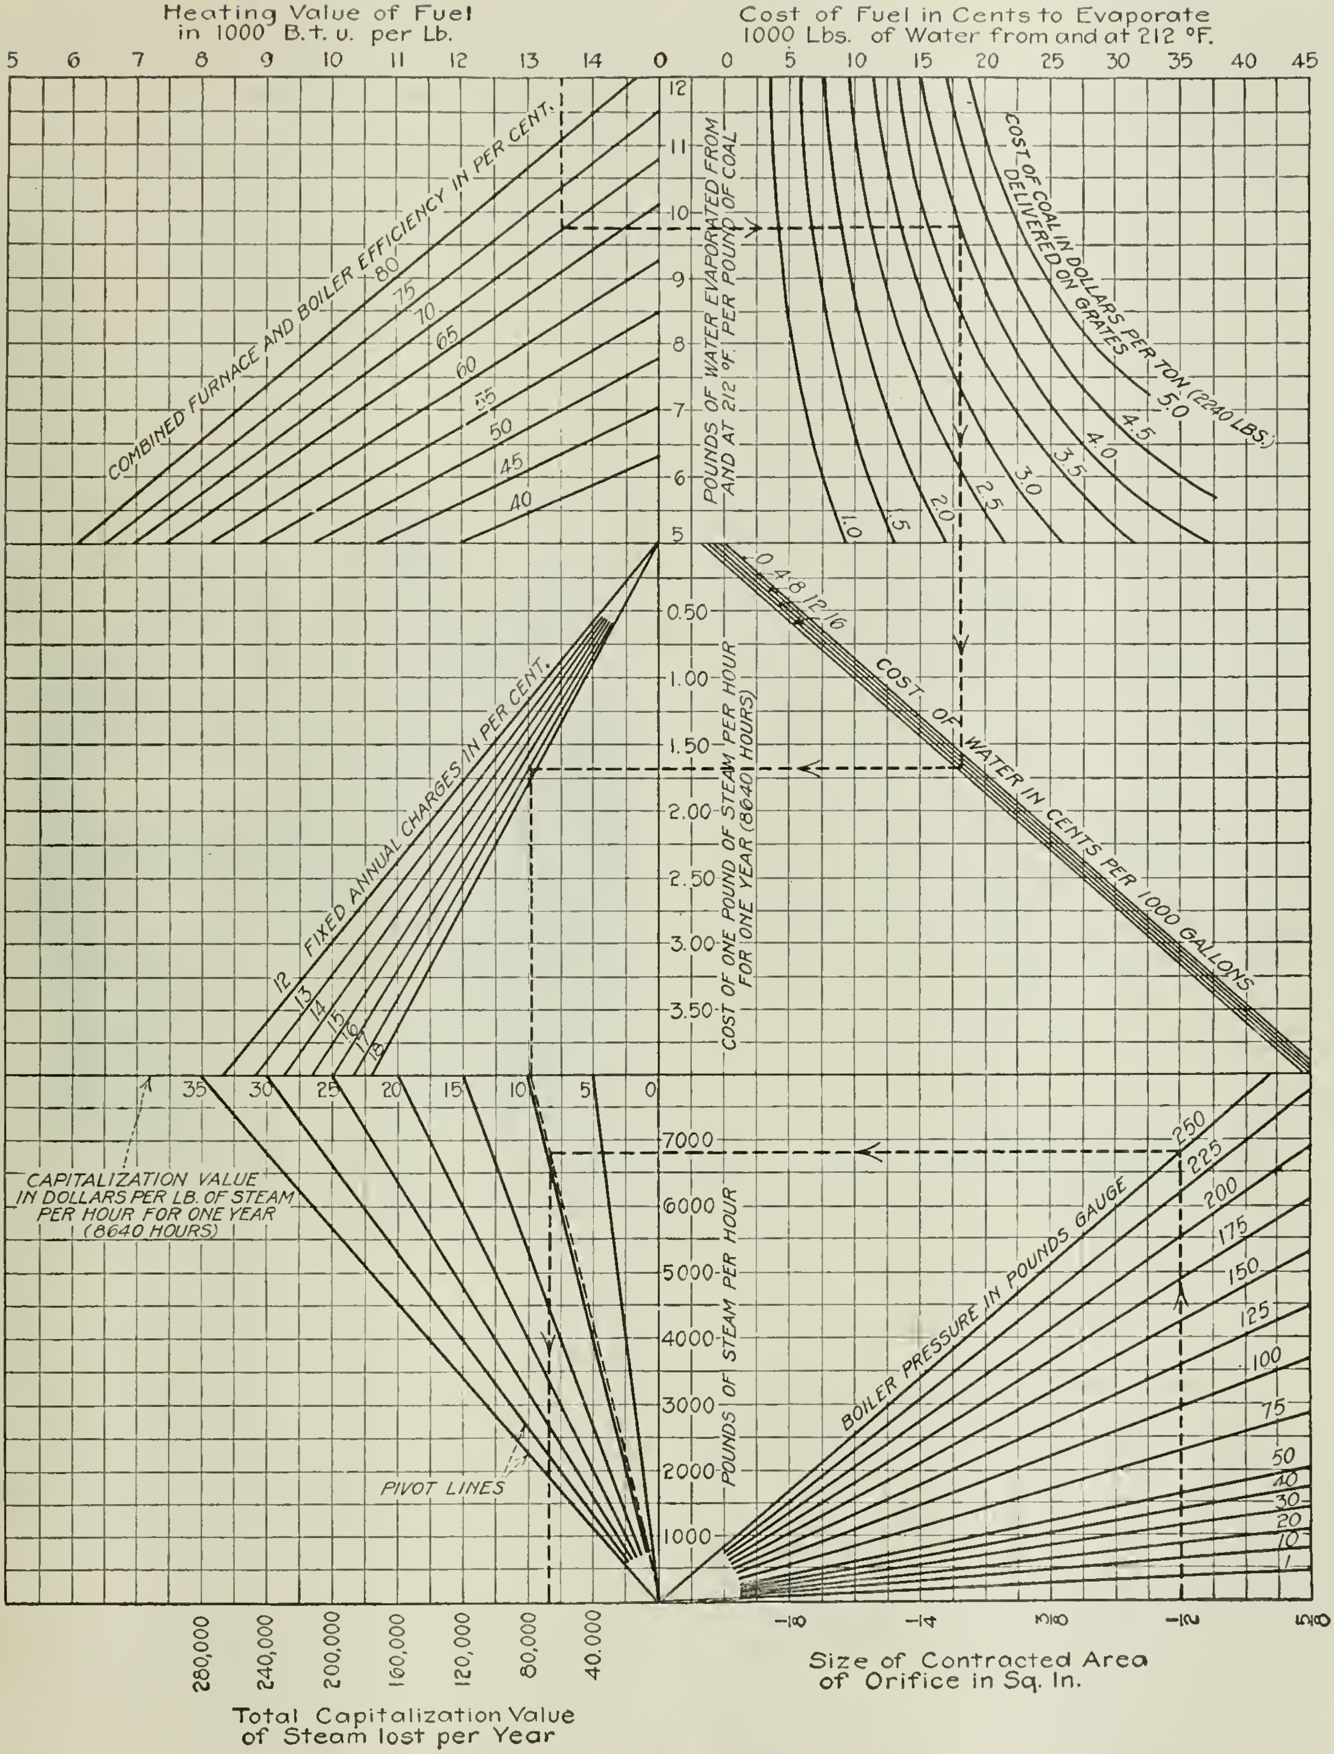

CHART SHOWS ANNUAL LOSS FROM STEAM LEAKS AND ITS CAPITALIZATION VALUE

continue to the left to the diagonal lines representing the fixed charges (taken at 17 per cent.), thence downward to the horizontal base line, giving the capitalization value per pound of steam per hour per year of 8640 hours (which is $9.94). From this point of intersection draw a diagonal line through the lower left-hand section of the chart to the point of intersection of the vertical scale, or center line. Then start on the base of the lower right-hand section of the chart at the point giving the contracted area of orifice (or the sum of all), which in this case is ½ sq.in., and follow upward to the intersection of the diagonal line, giving the steam pressure in pounds gage (in this case 250 lb.). From this intersection turn to the left, intersecting the vertical scale between the lower sections, giving the pounds of steam per hour (6804 lb. in this case), then continue across to the diagonal pivot line previously referred to (drawn from the capitalization value per pound of steam per hour for a year to the apex) and drop down to the horizontal base of the lower left-hand section, giving the total capitalization in thousands of dollars, which in the given case is $67,535.

The heat values for the foregoing problem have been reduced to feed water at 212 deg. and steam at 212 deg. F., or "cost of steam from and at 212 deg.," as is done in boiler-evaporation tests, because proper corrections must be made for the additional B.t.u. absorbed for the given conditions. The factor for reducing the weight of water actually converted into steam at any given pressure and feed-water temperature to the equivalent evaporation "from and at 212 deg. F." is called the "factor of evaporation," which is the ratio of the total heat necessary to produce one pound of steam "from and at 212 deg. F." to the heat used in heating the feed water from a lower temperature to steam at the temperature corresponding to the higher pressure, or is the difference between the total heat of evaporation under different conditions. Thus in the given case, for feed water at 160 deg. F. and steam at 250 lb. gage (264.7 lb. absolute) the factor of evaporation is found to be 1.1073, as per tables, or it can be determined by the following formula

$$F = \frac{H - h}{970.4}$$

when

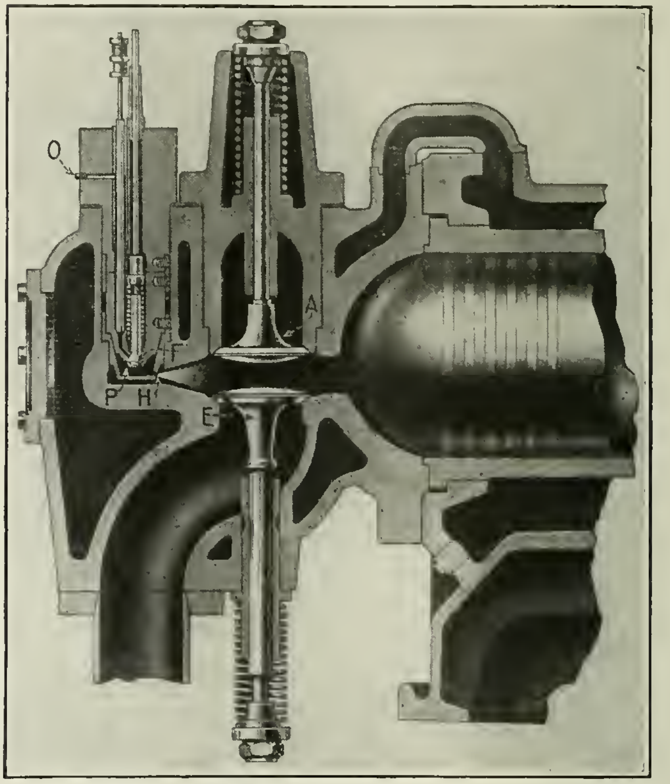
F = Factor of evaporation;
H = Total heat of steam above 32 deg. F. (from steam tables);
h = Sensible heat of feed water above 32 deg. F.;
970.4 = Latent heat of evaporation "from and at 212 deg. F."

Lyons Atlas Heavy-Oil Engine

A new type of heavy-oil engine has recently been placed on the market by the Lyons Atlas Co., Indianapolis, Ind. This engine, in contradistinction from many other types of heavy-oil engines, uses no air compressors or fuel pumps. The figure gives a cross-sectional view of the cylinder head, showing the position of the air, fuel and exhaust valves and the location of the piston at the end of the compression or the beginning of the power stroke.

On the first outward stroke the air valve A opens, and a charge of pure air is drawn into the cylinder during this stroke. Simultaneously with this operation, the fuel valve F opens and allows a small quantity of fuel oil to flow into the primary cup P, located in the combustion chamber attached to the cylinder head. The oil flows by gravity into the opening O, the amount being controlled by the governor according to the load and speed. On the return stroke all valves are closed and the charge of air in the cylinder is compressed into the combustion chamber to a pressure of about 450 lb. per. sq.in. This increases its temperature to about 900 deg. Fahrenheit.

When the piston has about completed its return stroke, the temperature of the air in the combustion chamber becomes high enough to vaporize the lighter hydrocarbons in the fuel, in the primary cup P, exactly the same way as in an oil-refinery still. This vapor is ignited by the high temperature and expands, creating a high pressure on the oil in the primary cup at almost the same instant that the piston reaches the end of the combustion stroke and is about to start on the power stroke. The pressure created in the primary cup, due to the burning of the lighter hydrocarbons, is sufficient to force the remaining liquid in the primary cup out through small holes H in the cup, causing the fuel to be broken up into fine spray as it enters the combustion chamber. Here the atomized fuel encounters the high temperatures due to compression, ignites and burns during the entire power stroke. The oxygen in the air admitted to the cylinder on the previous suction stroke is sufficient to result in very efficient combustion during the entire power stroke.



SECTION THROUGH ENGINE-CYLINDER HEAD

The combustion is gradual, no explosion taking place. Indicator diagrams show that the pressure in the combustion chamber rises very little above that due to compression of the air on the first return stroke. The force on the piston during the power stroke is similar to that on the piston of a steam engine.

During the second return stroke, or last stroke of the cycle, the exhaust valve E opens and the piston drives the burnt gases out to the atmosphere, thus completing the cycle when the piston reaches the end of the stroke. The amount of vapor burned in the primary cup is small, and its effect upon the pressure in the combustion chamber, as shown by an indicator diagram, is scarcely perceptible.

These engines are built in two sizes, 20 and 30 hp., and will burn crude and fuel oil, kerosene and intermediate distillates of such characteristics as to be thoroughly combustible and sufficiently liquid to flow freely at ordinary temperatures to the primary cup by gravity under a head of two feet. The fuel consumption, based upon a minimum net or effective heat content of 18,500 B.t.u. per lb., is guaranteed not to exceed 0.6 lb. at full load, 0.66 lb. at 75 per cent. full load and 0.78 lb. at 50 per cent. full load.

The engines are started by compressed air from a storage tank, on the oil they use for fuel, without any preheating or other preparation, and can start from a cold standstill and attain full speed in less than two minutes, regardless of climatic conditions.

A Breakdown Aboard Ship

By John Melville

The following account of a breakdown which happened to the engines of a steamer on which I was chief engineer may be of interest to *Power* readers in view of the active interest being taken in marine engineering at the present time.

We left Rotterdam (pre-war days) with a cargo of coal and proceeded down the river, everything running smoothly and well. Shortly after we had dropped the pilot and were heading at full speed for the Straits of Dover, a tremendous bumping caused me to rush to the engine room, where the second engineer already had the engines stopped. It had all happened so suddenly that there was no chance to locate the cause of the trouble, and nothing unusual showed to give us a clue. Being satisfied that something was wrong inside one of the cylinders, we proceeded to open them up. Their dimensions were: High-pressure, 25 in.; intermediate, 41 in.; low pressure 67 in.; stroke, 45 in. As far as the second engineer could judge, the noise came from the intermediate cylinder, but on opening it we found it in good condition. On opening up the high-pressure cylinder, however, we found a sorry mess; the piston was smashed into "a thousand and one" pieces, caused by one of the junk-ring bolts breaking at the end of the thread. There being insufficient clearance between the piston and cylinder cover, something had to go, and apparently the piston was the weakest part. Fortunately, after a few strokes the broken bolt got opposite one of the core plugs on top of the piston, and on the next stroke the core plug was forced in and the broken bolt jammed in the hole, thus preventing any further damage.

To operate the engines as a triple-expansion set was out of the question, so we made ready to run on two cylinders. The pieces of the broken piston were removed, but the piston rod with the crosshead and guide shoes was left in place, the piston rod thus serving to keep the gland steam-tight. With the piston valve and valve gear removed and the covers replaced, we were ready to proceed. The boiler pressure was reduced from 175 to 100 lb. No trouble was experienced in starting the engines, and we headed for Deal, where we could report the accident to headquarters. Orders were received there to proceed to Plymouth, where a new piston would be sent us.

The trip down the English Channel was uneventful though somewhat slow, but the engines gave no trouble, even though they were somewhat out of balance due to the cranks being at 120 deg. The coal consumption on the "pounds per indicated horsepower" basis was largely increased, but that was to be expected with a reduced initial pressure and the consequent reduction in the number of expansions by the loss of one cylinder. The limits of the valve gear prevented us cutting off early enough in the new high-pressure cylinder to give the previous ratio of expansion.

On arriving at Plymouth, the first job was to get the piston rod out to find out whether it had become bent in the smash. The limited means we had on board ship for testing proved that the rod was damaged, so it was sent ashore to a repair shop. When placed in the centers of a lathe, a double bend was found at the tapered part which fitted into the piston. The straightening of the rod, which was 6⅜ in. diameter, proved to be a difficult job, but by means of a charcoal fire, wooden blocks and mallets the blacksmith managed to get it nearly true and comparatively free from marks and scaling. When tested in the lathe again, only a slight cut was required to bring the tapered part true. This allowed the piston to go ⅛ in. farther on the rod, but there was sufficient clearance in the cylinder to allow for this.

Having got the new piston fitted to the rod, no time was lost in having it placed on board, where everything was ready to handle the job with dispatch. It was 2 p.m. when the piston and rod were on deck, but we were ready to sail by 10 p.m. On the voyage out and home again no defects developed, and so far as I know the same engines are doing duty still.

Some of the things we did, or rather the things we omitted to do, in connection with this job are open to criticism, such as neglecting to close up the steam ports in the high-pressure cylinder and not changing the cranks to 90 deg.; but the distance we had to travel to the nearest port was not great, and we were anxious to get under way again in the shortest possible time.

Another Coal and Liquid Fuel Mixture

A substitute for coal has been patented by the Industrial Fuel Corporation, of Long Island City, N. Y. The underlying scientific theory is, as outlined in the letters patent, the first claim being as follows:

> A fuel composition consisting of loose coal dust or screenings and a high boiling liquid fuel having low viscosity at ordinary temperatures, the amount of such liquid being merely such as will wet the faces of the coal particles without filling the voids therebetween to a substantial extent, and such liquid fuel being of sufficiently high boiling point to insure persistence of a substantial amount of liquid fuel in the mixture until such mixture is at or near the ignition point of the coal.

The composition is fired loose, the same as ordinary coal.

In other words, a liquid having the easy flowing qualities of water is mixed in the proportion of 1 to 20 with anthracite screenings. Because of the high boiling point of the liquid, it remains with the screenings, keeping the mass moist, up to the point at which the carbon in the coal ignites, and once the loose material actually begins to burn, the problem of stability in the fire is solved.

According to the New York *Sun*, this idea of burning low-grade fuel was anticipated by the New York Architectural Terra-Cotta Co., of Long Island City.

> Many months ago this company was unable to buy any soft coal in the New York market, but had no difficulty in securing culm. Prior to that time, an officer of the company had found that by mixing about 5 per cent. of a special liquid fuel with 95 per cent. of this coal dust a fuel might be obtained of such consistency that it would neither fall through the grate bars nor go up the chimney under forced draft.
>
> The experiment was tried out in practical use and proved to be a complete success. For many months this company has used no other fuel under its boilers and has obtained a maximum of efficiency with a saving of nearly 50 per cent. in expense.
>
> The new fuel was examined by Dr. C. E. Davis in the laboratories of the Columbia University Department of Chemical Engineering and upon calorimeter test showed a calorific value of 13,950 B.t.u. to the pound, or a heating value about equal to that of anthracite.
>
> The special liquid referred to is a byproduct obtained in the manufacture of carburetted water gas and has always been considered of minor importance. Millions of gallons are produced annually in the United States.

It would seem from the foregoing that this fuel is along the line of similar fuels in which a binder is mixed with fine coal before it is pressed into briquets. In this instance, however, the coal and binding mixture is fired in a loose state.

Oil Lantern Jammed on Piston Rod

By E. W. Miller

The machine was of 50-ton capacity, having two double-acting ammonia compressors with the steam cylinders between the two, the entire unit being vertical. A knock developed and gradually grew worse, sounding like that produced by striking a large piece of metal with a light hammer.

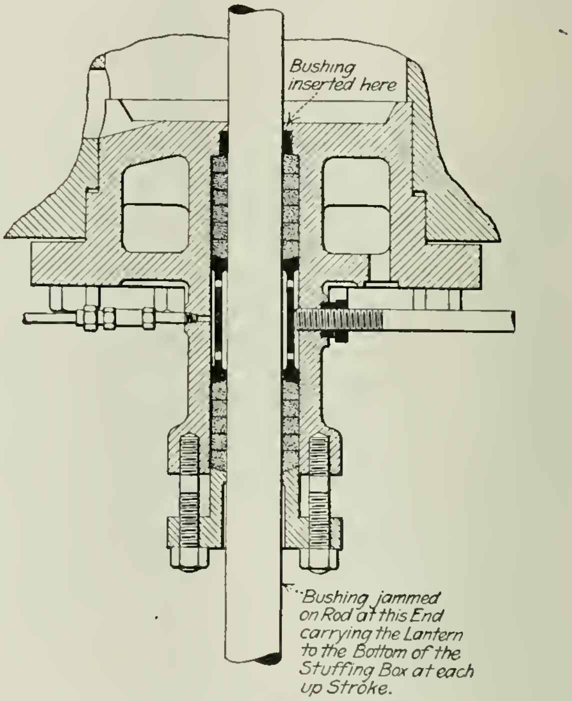
The engineer concluded that it was in one of the compressor valves. He had expected by the sound of the machine to find that one of the springs had broken or become too weak, but was surprised to find that the valve and spring were in good order. He oiled the valve liberally and took particular care in replacing it to make sure that there should be nothing to interfere with its operation.

When he started the machine, the knock was as bad as before. It seemed impossible to find the source—so much so that he thought at times that it was somewhere in the steam cylinder or its valve gear. Finally, he shut the machine down and went over every part of the compressor, removing the valves, testing the clearance and keying up on all the bearings and taking up all lost motion.

The knock was still there when he started the compressor again, and the machine was once more shut down and pumped out and the piston removed from both the one ammonia compressor and the engine. The engine piston was removed first and nothing wrong was found. When he came to remove the compressor piston, he found that it came out with difficulty, and to facilitate its removal it was decided to remove the packing.

When the packing had been removed up to the oil lantern, it was found that the lantern refused to budge. The piston was lowered in the cylinder, and at the same time one of the men maintained a steady pull on the lantern. It came down without any trouble. When the piston was lowered sufficiently to bring the lantern out of the stuffing-box, it was found that the lantern was jammed fast on the piston rod at this point. The lantern had been babbitted and turned to a snug fit on the rod, and at some time the rod had become hot enough to partly melt the babbitt. At the same time some shreds of packing had worked through some of the holes in the center of the lantern and squeezed into the molten babbitt, and when the babbitt set again, probably due to a sudden cooling of the machine from a slug of liquid in the suction gas, it had formed a tight fit on the rod. The packing had wedged between the rod and lantern and practically clamped the lantern on the rod.

When the lantern had finally been removed from the rod, the engineer turned his attention to removing the rest of the packing that should be above the lantern in the stuffing-box. To his surprise there was not a shred of it left. The reason for the pound or knock was now plain to him. With no packing in the top half of the stuffing-box and the lantern jamming hard on the rod at the crank end, the lantern had struck the bottom of the stuffing-box at every up stroke of the compressor, and of course the knock resulted.



STUFFING-BOX FOR AMMONIA COMPRESSOR

The engineer was at first badly puzzled to account for the disappearance of the packing above the lantern, but when the rod was again inserted, he found that there was nearly $\frac{1}{8}$ in. clearance between the rod and the neck of the stuffing-box. The rod had been turned down some time previous to this, and no provision had been made to make up for the reduced diameter. This was now provided for by making a junk ring $\frac{3}{4}$ in. thick and a snug fit in the stuffing-box and $\frac{1}{32}$ in. larger inside diameter than the rod. This was slipped over the rod and placed at the bottom of the box. It prevented the packing from working out between the rod and the neck of the stuffing-box and ended the trouble with this stuffing-box as well as eliminating the puzzling knock.

Future Location of Central Power Stations

By DEVER C. ASHMEAD

The coal mines are able to produce all the coal required, but the transportation facilities are not adequate; therefore, it is suggested that the country be divided into districts, each served with electric power generated by central stations located at the sources of fuel supply. The advantages of the plan are outlined, and estimates of the probable saving are given.

THE fuel problem does not lie in the inability of the mines to produce the coal, but rather in the inability of the railroads to transport it. The matter is one of transportation instead of production. The country requires 600,000,000 tons of coal per year, and the mines can furnish 750,000,000 tons in that time; but the railroads cannot handle more than 550,000,000 tons a year, or 50,000,000 tons less than the normal demand.

The failure of the railroads to handle the required quantity of coal is due to three factors: First, lack of motive power; second, shortage of cars; and third, delay of the consignee in unloading cars. This article is not concerned with the last of the foregoing causes, but it is vitally concerned with the other two. Any practicable method of relieving the shortage of locomotives and cars must be of interest to the whole country; therefore, it will be advisable to investigate at least one phase of the situation.

Increase in Use of Electrical Energy

According to the United States Census Reports, the electrical energy generated in 1907 is estimated as 10,621,407,000 kw.-hr., and in 1912 as 17,585,622,000 kw.-hr. In 1917, according to careful estimates, over 27,000,000,000 kw.-hr. was sold by central stations, which is 16,378,593,000 kw.-hr. more than was generated in 1907, or an increase of approximately 155 per cent. in ten years. It is realized that the figures for 1907 represent current generated and those for 1917 represent current sold, so that they are not strictly comparable. However, the amount of energy generated in 1907 is not obtainable; and furthermore, if losses were included, the value 27,000,000,000 kw.-hr. would be considerably increased. This increase would serve only to strengthen the argument put forth in this article; consequently, the two values are compared as shown.

It is not unreasonable to assume that in the next ten years the use of electricity will increase in the same ratio, which means that in 1927 the output would be 68,850,000,000 kw.-hr. About one-third of the electrical output in 1917 was produced by hydro-electric plants; therefore, at the same ratio, 46,000,000,000 kw.-hr. would be generated by steam in 1927. It requires from 2 to 10 lb. of coal to produce a kilowatt-hour. If an average of 3 lb. is assumed, which certainly is conservative enough, it follows that the 18,000,000,000 kw.-hr. produced in 1917 required 54,000,000,000 lb. of coal, or 27,000,000 short tons.

To handle this tonnage, the railroads had to move 675,000 carloads of coal averaging 40 tons to the car. By 1927 these figures will have increased to 138,000,000,000 lb. of coal, or 69,000,000 short tons; and estimating 50 tons of coal to the car, since by that time all the small cars will be scrapped, there will be 1,380,000 carloads.

In 1917 there were approximately 950,000 coal cars in the United States and more than two-thirds of the number were required to make one trip from the mines to the power plants to furnish the needed coal. The money paid to the railroads for freight on this coal, taking a freight rate of $1.50 a ton, amounted to $40,500,000, which is interest at 5 per cent. on $810,000,000.

Assuming the same freight rate, producers of electricity in 1927 would pay the railroads $103,500,000 a year, which is the interest at 5 per cent. on $2,070,000,000. If the latter sum were used to develop the electrical industry, a wonderful advance could be made. It is advisable, therefore, to investigate the distribution of the use of electricity and its relation to the coal fields of the United States.

Generation of Power at Coal Mines

Table I gives the production of coal and coke in the several states in 1916. Table II shows the amount of current generated in the several states and the coal required to produce this current, in 1917 and 1927. The greater part of the electrical production is comparatively near the different coal fields, which naturally suggests the idea of generating current at the source of fuel supply instead of at the point where the power is used. In these days of high-tension electrical transmission over long distances, this suggestion has greater force.

As shown on the accompanying map, the writer divides the country into 23 districts, each supplied with electricity generated from one or more central stations, which are indicated by black dots. Table III gives the total kilowatt-hours and the quantities of coal to produce them in these districts, for both 1917 and 1927. Of course the actual working out of a plan of this kind would probably differ greatly from the districting here shown, but the latter will serve to illustrate the idea.

Objections to Plan as Outlined

The first objections to such a plan would probably be the cost of the necessary transmission lines and the loss due to the abandonment of existing central stations. Approximately 100,000 miles of transmission lines at about $15,000 a mile would be required, involving the huge sum of $1,500,000,000. Plants now in operation would be worth only their scrap value, which would entail a loss of another $1,500,000,000. Thus, the total investment required would be $3,000,000,000.

It was shown that the saving in the cost of transporting coal in 1917 would have amounted to $40,500,000, and that in 1927 it would amount to $103,500,000 if the power were generated at the mines. In Pennsylvania, 88,312,000 tons of anthracite was mined in

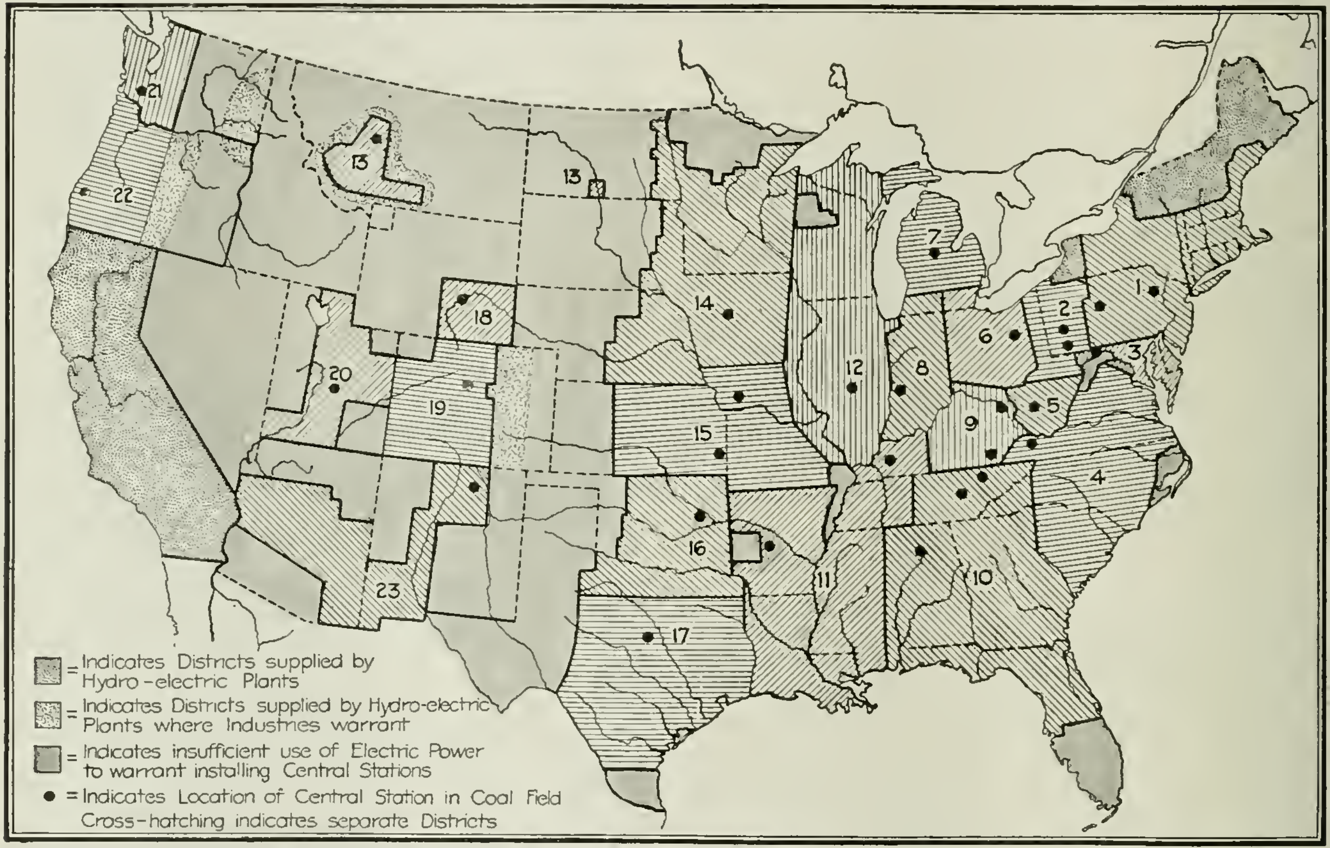
1916, of which 8 per cent. was too fine to ship. This 8 per cent., amounting to 7,000,000 tons, would generate one-fourth of the electricity used in the United States in 1917. This grade of fuel, which can be burned successfully on chain-grate stokers, could be flushed with water and pumped through pipes from the mines to the power stations, where the water could be drained off and the coal dried for burning. Such silt could be obtained at the central station for approximately 75c. a ton less than No. 2 buckwheat or bird's-eye coal at the mine, and its use would save $5,250,000 a year.

Another saving could be made in the coke regions. In 1916 approximately 37,000,000 tons of coke was produced from beehive ovens. Each ton of coke produced about 5 per cent. of coke breeze, or nearly 1,900,000 tons, in 1916. Manufacturers of coke now pay to have it hauled away; but if it were sold for even 40 or 50c. a ton, replacing coal at $2.50 a ton, there would be a saving of about $3,800,000 a year to the fuel user.

Further saving would be effected by reducing the loss of coal in transportation, due to leakage, wrecks and stealing. This loss may run from 2 to 5 per cent. Taking the lower value, the loss in 1917 was 540,000 tons and in 1927 it would be 1,380,000 tons. Assuming a price of $2.40 a ton at the mine, the loss would be $1,300,000 in 1917 and $3,300,000 in 1927.

In mining bituminous coal by machines, an undercut about 6 in. deep is made, and the fine coal, or "bug dust," thus formed is about 8 per cent. of the coal mined, or 39,500,000 tons in 1917. Subtracting the 5,500,000 tons used in the production of coke, 34,000,000 tons remain, and if it were screened out of the coal and used for the production of power, the value of the remainder of the coal would be increased. If the saving amounted to only 10c. a ton, the saving in 1917 would be about $3,400,000.

Further saving would result from the more economical burning of fuel and generation of power, since electricity can be generated more cheaply in a large plant than in a small one. At present there is great waste of coal in hand-fired plants; much is wasted by the old types of mechanical stokers, and more is wasted by the use of unsuitable grates. The reduction of these losses would probably save millions. The reduction in cost of labor and supervision by substituting a few large plants for many small ones would also run into millions.



MAP SHOWING TENTATIVE DISTRICTING, WITH LOCATIONS OF CENTRAL STATIONS SUPPLYING VARIOUS DISTRICTS WITH POWER GENERATED AT MINES

The various estimates that have thus far been considered may be summarized as follows:

	1917	1927
Tons of coal required for estimated kw.-hr.	27,000,000	69,000,000
Freight paid to railroads	$40,500,000	$103,500,000
Saving by using anthracite silt	5,250,000	5,250,000
Saving by using coke breeze	3,800,000	3,800,000
Saving by using bug dust	1,750,000	3,400,000
Reducing loss of coal in transportation	1,300,000	3,300,000
Total	$52,600,000	$119,250,000
Equivalent principal, taking interest rate of 5 per cent	$1,052,000,000	$2,385,000,000

If the foregoing economies could be put into effect at once, the saving would pay the interest at 5 per cent. on more than a billion dollars, while in 1927 it would pay the interest on almost two and a half billions. These figures do not take into account the other savings mentioned. If their values were added, the total saving in 1927 would probably be more than enough to pay the interest on the required three billions of investment. The feasibility of the scheme, from a financial viewpoint, is thus demonstrated. It remains to see whether it is practicable.

A careful study of Tables I and IV, in connection with the districts shown on the map, indicates that each district produces enough coal of the right grade or quality to meet its demand for power. Table IV gives the coal and coke production, by districts, in 1916.

TABLE I. PRODUCTION OF COAL AND COKE IN 1916, IN SHORT TONS

	Coal	Coke
Alabama	16,250,000	4,250,000
Arkansas	2,000,000	..
California	12,000	
Colorado	10,260,948	1,320,000

Virginia	227,000,000	340,000	578,850,000	867,000
Washington	579,000,000	869,000	1,476,450,000	2,215,950
West Virginia	113,000,000	169,000	288,150,000	430,950
Wisconsin	349,000,000	524,000	889,950,000	1,336,200
Wyoming	18,000,000	27,000	45,900,000	68,850

* Coal consumption for generating electric power is practically nothing.
† Coal consumption for generating electric power is negligible.

Table V shows the length of transmission lines needed in each district.

The arrangement of the central stations is a matter of study for each individual district, but some suggestions can be made. In some districts it might be better to have a number of small stations located at the different mines and supplying power to a main transmission line. In the Indiana district, for example, the coal field is a long, narrow strip on the western border, and there are a number of mines with an output of 500,000 tons of coal a year each. A central station could be located at each of these mines and take its entire output, and each would produce about 330,000,000 kw.-hr. a year.

TABLE III CURRENT GENERATED BY STEAM, AND SHORT TONS OF COAL BURNED, BY DISTRICTS

District	1917		1927	
	Kw.-Hr.	Coal	Kw.-Hr.	Coal
1	6,701,000,000	10,051,500	17,087,550,000	25,631,325
2	1,340,000,000	2,010,000	3,417,000,000	5,125,500
3	632,000,000	948,000	1,611,600,000	2,417,400
4	295,000,000	442,500	752,250,000	1,128,375
5	59,000,000	88,500	150,450,000	225,675
6	812,000,000	1,218,000	2,070,600,000	3,105,900
7	123,000,000	184,500	313,650,000	470,475
8	782,000,000	1,173,000	1,994,100,000	2,991,150
9	479,000,000	718,500	1,221,450,000	1,832,175
10	475,000,000	712,500	1,211,250,000	1,816,875
11	448,000,000	672,000	1,142,400,000	1,713,600
12	2,654,000,000	3,981,000	6,767,700,000	10,151,550
13	17,000,000	25,500	43,350,000	65,025
14	634,000,000	951,000	1,616,700,000	2,425,050
15	721,000,000	1,081,500	1,838,550,000	2,757,825
16	205,000,000	307,500	522,750,000	784,125
17	210,000,000	315,000	535,500,000	803,250
18	18,000,000	27,000	45,900,000	68,850
19	316,000,000	474,000	805,800,000	1,208,700
20	76,000,000	114,000	193,800,000	290,700
21	579,000,000	868,500	1,476,450,000	2,214,675
22	293,000,000	439,500	747,150,000	1,120,725
23	17,000,000	25,500	43,350,000	65,025

Another example may be found in the anthracite field. There might be three large central stations, one in each part of the field. As these plants could burn silt and fine coal, their fuel could be pumped from the various breakers to the central plants, relieving the railroads from handling it.

Still another example is the eastern Kentucky field, containing three main railroad lines on which the coal is produced. It might probably be best in this field to have three main power plants, one on each of the three railroads.

TABLE IV. COAL AND COKE PRODUCTION IN SHORT TONS, IN 1916, BY DISTRICTS

District	Coal	Coke	District	Coal	Coke
1	128,312,000	2,600,000*	14	7,614,000	....
2	149,270,000	28,746,000	15	12,000,000	.....
3	4,930,000	395,000*	16	3,053,543	......
4	33,300,000	2,600,000	17	2,300,000	....
5	44,989,000		18	7,650,000	2,300,000
6	30,500,000	725,000*	19	10,260,948	1,320,000
7	1,056,393		20	3,621,935	224,294
8	18,738,256	3,100,000*	21	3,000,000	140,000
9	11,000,000	980,000*	22	39,230	
10	22,979,915	4,550,000	23	3,893,185	479,153
11	16,106,500				
12	63,500,000	2,750,000*		582,423,212	50,909,447
13	4,308,307				

* Byproduct coke.

In the bituminous field it would probably be better to have a number of smaller plants located at convenient points, so that the slack coal would need to be carried a minimum distance by the railroads. Such a plan would be better than having one or two large plants, as the latter would involve a longer haul.

TABLE V. LENGTH OF TRANSMISSION LINES, BY DISTRICTS

District	Miles	District	Miles
1	14,300	15	8,500
2	5,900	16	4,000
3	1,800	17	4,000
4	6,700	18	600
5	2,100	19	2,000
6	4,800	20	1,000
7	4,000	21	2,000
8	6,300	22	1,000
9	2,500	23	3,000
10	9,500		
11	8,500		123,300
12	15,500	Less 21, 22 and 23	6,000
13	1,000		
14	14,300		117,300

It has been shown that electric companies and users of power would benefit by electric-power generation at the mines. Now it remains to be shown how the railroads would be benefited by the reduction of the burden of transportation. In 1915 there were about 900,000 railroad cars in use in the United States for hauling coal, and 344,119,502 tons were hauled. At 40 tons to a car, there was a total of 8,602,988 carloads, so that each car made 9½ trips a year from the mines to the consumer. As there were 675,000 cars of coal handled in 1917 for electric plants alone, it was necessary to keep about 71,000 cars in this service. In 1927, assuming the same number of trips per car, but 50 tons to a carload, there would be 1,380,000 carloads, requiring 145,000 cars. The locomotives needed to handle these cars, assuming 50 cars to a train in 1917 and 60 in 1927, would be 1400 in 1917 and 2890 in 1927. The reduction in the amount of coal handled, by generating the power at the mines, would be enormous. Of course the revenue from the freight on this coal would be lost to the railroads, but the equipment thus released could be turned to the carrying of other commodities, so that their income would not necessarily be affected adversely.

Precedents for Long-Distance Transmission

At the present time there are a number of precedents for the long-distance transmission of power and for the establishment of central stations at the source of the fuel supply, and it might be well to show what has been done. A number of examples of long-distance transmission of power exist in the West, particularly in California, one of the most noteworthy being that of the Stanislaus system. This is a hydro-electric plant in the Stanislaus Mountains. It has a capacity of 100,000 kw. and transmits power at 110,000 volts to San Francisco, more than 150 miles away. This plant has been in operation since 1907.

There are a number of plants east of the Mississippi River which have their central stations at the mines and distribute power over a considerable extent of territory. The Rochester & Pittsburgh Coal Co., at one of its operations in Indiana Co., Penn., transmits power for a distance of about 30 miles at 22,000 volts. This plant is typical of those which use waste fuel, as it burns bone coal. Such coal is commercially worthless, due to high ash content and lack of luster, but it has to be removed from the mines. This plant has an installation of 12,000 kilowatts.

At Cabin Creek Junction, W. Va., the Virginia Power Co. has installed a plant of 20,000-kw. capacity and arrangements have been made to increase it. Current is transmitted at 44,000 volts to hundreds of coal mines within a radius of 50 miles and the company is now considering extension of the lines.

At Hauto, Penn., a plant of 37,500-kw. capacity, which is to be enlarged to 100,000 kw., has been built by the Lehigh Coal and Navigation Co. The current is transmitted at 110,000 volts for distances up to 50 miles. The plan is to extend the lines eventually to New York and Philadelphia, 98 and 73 miles away, respectively. This current is used to supply a large number of mines and manufacturing plants, and a very small grade of coal is used.

Near Wilkes-Barre, Penn., the D., L. & W. R.R. at its Loomis mine has an installation of 10,000 kw. and transmits the current at 22,000 volts to a number of mining operations. Silt is used for the generation of steam.

At Peoria, Ill., there is a central station with a capacity of 10,500 kw. supplying a population of 140,000 people in five counties having 27 cities and towns. Two mines very near the central station furnish the coal, and the current is transmitted at 33,000 volts.

The Christopher Coal Mining Co., Christopher, Ill., has an installation of 5000 kw., and all the surplus power is stepped up to 33,000 volts and supplied to a public-utilities company.

The Kentucky Utilities Co. has a plant in the Pocket near St. Charles, Va., and another at Varilla, Ky. The Pocket plant is of 10,000 kw. and the Varilla plant of 5000 kw. The Varilla plant is supplied with coal by a company whose tipple is about 500 ft. away, while the Pocket plant is supplied by the coal mines at St. Charles and the washer at the Pocket. These plants are connected by more than 50 miles of transmission lines, and they supply a territory more than 150 miles long, which is being extended monthly· 33,000 volts is used for the transmission of the current.

The Clearfield Bituminous Coal Corporation has a 2000-kw. plant at Clymer, Penn., and a 5000-kw. plant at Rossiter, Penn. The Clymer plant is tied in with the Pennsylvania Public Service Corporation lines, and the one at Rossiter is about to be. The service corporation supplies a number of counties in the central part of Pennsylvania with 22,000-volt current. At present the lines are more than 150 miles long and are being extended.

Packing Water-Pistons of Pumps

Packing the water end of an internally packed pump is considered a comparatively simple job, but the life or service of the packing is greatly influenced by the way it is put in and adjusted. The one big requisite is that the packing be pinched or clamped firmly between the flange and the follower plate. When so clamped, it can withstand the action of the water without being washed away. This is especially noticeable when the pump cylinder has become worn large in the middle so that there is more or less water slip toward midstroke. If the packing is not solidly gripped, it will not stay long, will be washed away; if, however, it is held as in a vise, it will withstand the erosion and "tugging" effect a much longer time.

The packing cannot be expected to expand to suit the worn part and compress to pass into the smaller portion at the ends, as the rings in the steam end do, and still last a reasonable time, because of its fibrous nature.

A split ring should be put in, if necessary, just ahead of the last ring so that the packing will extend slightly beyond the plunger and the follower plate will pinch it hard before coming against the face of the plunger.

By doing without needless luxuries you can save money. And by investing that money in War Savings Stamps, you automatically release to the Government the labor and material that it needs for winning the war. The Government doesn't ask you to give your money, or to do without luxuries forever. Uncle Sam simply wants your game of pleasure and luxury postponed on account of the rain of bullets that the Huns are directing at our fighting lads.

Editorials

"We'll Stand Fast"

Words of Inspiration from "Power's" Paris Correspondent

IN THE world crisis precipitated by the German onslaught in Picardy and Flanders the faith of France in her own armies and those of her allies remains absolutely unshaken. This is the clear-cut impression gained by the observer in Paris today. There is no panic here as Teuton propagandists would have the world believe, nor are there discernible even the symptoms of a general uneasiness.

Long-range shelling by day, bombing raids from the air by night, and the threat of a German advance upon the French Capital, far from demoralizing the spirit of the civil population, have lifted it to new heights of determination and confidence. The daily news from the front is even more encouraging, and there are just beginning to drift back hints of the heroic part which the engineers of the allied forces are playing in the greatest war drama of all time.

When the full story is told of how they have been performing day after day seemingly impossible feats in transporting reserve troops and material and in maintaining lines of communication, it will form the grandest epic in the annals of engineering.

From the picture of public feeling here I will pick out a single detail. At the *pension de famille*, where I stay, lives the aged widow of a French general. Amid the bursting shells of the long-range gun, bombs dropped in the night and early rumors of an overwhelming German attack, her friends attempted to persuade the old lady to leave Paris. I saw her eyes flash, her bent shoulders straighten back, and as she snapped, "*Je reste ici*," she seemed to embody in those three words the spirit of France—"We'll Stand Fast."

Mine-Mouth Generation of Power

THE plan outlined in the article on page 661 of this issue suggests locating large electric power stations in the heart of the coal-mining districts of the country, generating electrical energy there and transmitting it by high-tension lines to the points where power is required. The idea is not a new one, for it has been put forth, in one form or another, in times past. But the exigencies brought about by war conditions lend fresh emphasis to the proposal.

It is at once apparent that the utilization of coal for power generation at the mine does away with the necessity of transporting that coal to distant points and so relieves the railroads of a vast amount of tonnage. So far as the past season is concerned, the congestion of traffic on the railroads was due to lack of motive power to handle the increased quantity of freight. Obviously, any arrangement by which a large percentage of the freight traffic could be eliminated would afford a solution of the transportation problem.

The large power plant is capable of producing energy at a lower cost than the small plant working under like conditions, so that the plan proposed has the additional advantage of economizing in the use of fuel. This, too, has been brought prominently into notice of late.

The author, for the purpose of presenting his argument, divides the country into a number of districts, each of which contains one or more coal fields of sufficient size to furnish the power for that district. The division shown is made arbitrarily, and any definite attempt to put such a plan into operation would probably alter the boundary lines considerably.

The current generated at the district central stations is transmitted to various parts of the district by high-tension transmission lines. The lengths of these lines in some cases would be great, but there are a sufficient number of long-distance transmission lines now in operation to furnish the necessary precedents.

A further step, not mentioned by the author in his discussion, would be the recovery of byproducts from the coal before it is utilized as fuel. This point is now under consideration in Great Britain, in connection with a plan to divide that country into some sixteen districts, each containing electric generating stations as centers of supply of power. The idea is to build the byproduct plant in close proximity to the power plant and to extract from the coal all desirable byproducts before using it to produce heat for power, where such extraction proves justifiable.

All these plans for the utilization of the greatest possible percentage of the value of coal are straws showing that the trend of modern engineering is in the direction of greater efficiency and increased conservation of natural resources.

The Coal Situation

THE problem of supplying every coal consumer in this country with sufficient fuel to meet his needs for the coming winter hinges entirely on transportation, and the Fuel Administration gives assurance that there are enough cars and locomotives to transport the necessary quantity of coal, provided that every car and every locomotive are used to their maximum capacity every day in the year. Also, there are enough mine workers to furnish the required output, if they are kept busy every day in the year and if the cars and locomotives are available.

The full coal-carrying capacity must be utilized all the time, and to attain this end it is necessary that the coal operators be supplied with orders. If orders are delayed, or are small, the output at the mines will be curtailed correspondingly, resulting in idle workmen; but still worse, the number of coal cars delivered to the mine will be reduced to suit the demand, and coal-carrying equipment will be idle.

There is no elasticity in the transportation of coal. The movement must be continuous and always at full capacity, if a fuel famine like that of last year is to be averted. The aggregate demand for coal is so great that a slump in production during a week or a month cannot be made up in a succeeding period.

The Fuel Administration is doing everything in its power to keep all the machinery for the production and distribution of coal working at maximum capacity. The reduction of thirty cents a ton to the domestic consumer is made in the hope that orders for the winter's coal will accumulate to such an extent that both the mines and the railroads will be kept busy continuously throughout the year.

The producer is not able to mine the coal and store it in anticipation of a future demand. Few mines have storage space or equipment; and even if these were available, there would be an unnecessary expense incurred in the double handling of the coal. The most economical and rapid method is to mine the coal, load it directly into cars and ship it to the points where it is to be used, there to be stored until it is needed.

The Fuel Administration will coöperate with any community that desires to provide storage for emergency stocks of coal to be laid in during the summer months; but the greater part of the storage capacity of the country is made up of the bins of the individual consumers, and these are the logical places for the accumulation of stocks of fuel.

The Government has established a schedule of fixed prices for coal at the mines; it has put into effect a zone system of distribution to facilitate transportation; it encourages the production of clean coal by allowing higher prices to producers who take extraordinary pains in preparing their output; and it penalizes in price those coals that contain undue amounts of foreign matter. In view of these measures the prompt and complete coöperation of the consuming public by the placing of orders is needed to insure the successful distribution of the year's coal.

Home Army Must Supply Power

THERE are two fields of battle in the war against German autocracy and militarism, and to win the war we must conquer on both those fields. One is in France and Belgium and extends from the North Sea to the Swiss border. The other is here in America. It extends from the Atlantic to the Pacific and from the Canadian border to the Gulf of Mexico. It covers every city, town and village, every farm, field and woodland in the country.

In France our soldiers, standing shoulder to shoulder with the British, French and Italians, repeat the great French battle cry of Verdun, "You shall not pass!" Their breasts are a wall of steel against the charging masses of the Kaiser. Amid the roar of cannon, the rattle of machine guns and the clash of bayonets, they stand firm.

Over here it is the noisy clang of the riveters in the shipyards, the busy hum of the factory, the whirring wheels of smoothly running engines, the silent efficiency of the great office force, the push of the plow in soft earth and the swift stroke of the woodman's ax.

All are fighting in the great battle that democracy may live—those whose part is played here, as well as those who sail across the sea to offer their lives in France. And it is as essential for final victory that the army here shall stand firm—the army of workingmen and workingwomen—that no part of the long line shall give, that every man shall put forth the last ounce of his strength, that they shall fight with their backs to the wall, as it is that that line in France shall hurl back the German hordes. For our men over the sea cannot win without us at home. They look to us to back them up, to keep a steady stream of men and munitions and supplies of all kinds crossing the Atlantic, to build the ships that will bridge the ocean.

Our duty is as stern as is that of the soldiers in France, and our fate is as unrelenting. Our choice is unremitting labor and unquestioning, willing sacrifice, or defeat and subjugation to the iron despotism of Germany. There are no other alternatives.

The Third Liberty Loan campaign is ended, and the loan well oversubscribed. The response of the people of America has been more than equal to the present demand. They have done well, but this is not all. Let us now concentrate our energies to putting the War Savings Certificates over the top, for they are also a liberty investment that our Government is depending upon to provide the sinews of war. The line on the battlefields of America must not waver, so that the line in France will hold firm, because our men in France put their faith in us in America. Let us not fail them. Let us be equal to any call that is made upon us. Let us now buy War Savings Certificates to the limit of our resources, and then strain our resources to buy more Government securities. In that way lies victory.

Boilers not built in conformity with the Code may be carried into Pennsylvania, but may not be operated, according to an opinion recently rendered by the Attorney-General's Department to the Department of Labor and Industry. The board had ruled that boilers not built in conformity with its boiler code may not be brought into Pennsylvania. The Legal Department is of the opinion that such a ruling cannot be enforced, but that the board can prevent the operation of the boiler until it is made to conform with its code.

Which will you choose? The Government needs all the money, material and labor it can get, and more. This is a war of equipment. No matter how brave our men are, they cannot face the greatest military organization the world has ever known with bare hands. There is not enough labor and material in the country for our usual comforts and luxuries and for our fighters' necessities. We must choose which it shall be.

There's an old saying that it's better to have tried and failed than never to have tried at all; but while it may be right to look at some things in that way, it cannot be applied to all tasks and problems that one meets with in the power-plant field. Overconfidence in one's ability will as surely bring failure as would lack of sufficient courage to tackle the job.

Farley G. Clark, of Niagara Falls, N. Y., proposes to pump coal from mines to centers of consumption through pipe lines. The idea is worthy of study.

Correspondence

Meeting an Emergency

The plant of which I have charge supplies light and heat to a large railway terminal hotel, station buildings, etc. We have two boilers, but use only one at a time, the other being kept clean and ready to fire up at a moment's notice. We burn oil pumped directly to the burners from the underground storage tank, which is about 200 ft. from the boiler room. One 3 x 2 x 4-in. duplex pump is used at a time, supplied from a common 3-in. suction line. This line comes out of the tank above the level of the pumps, drops considerably below their level, then rises through the boiler-room floor to the pumps after making a number of right-angled turns. The pumps run very slowly, controlled by a governor, to supply the oil as fast as it is burned. We have no trouble as long as the oil tank is not less than half full, as the oil is above the level of the pumps; but below this the pump frequently loses the oil, and it is sometimes difficult to get it to pick up again.

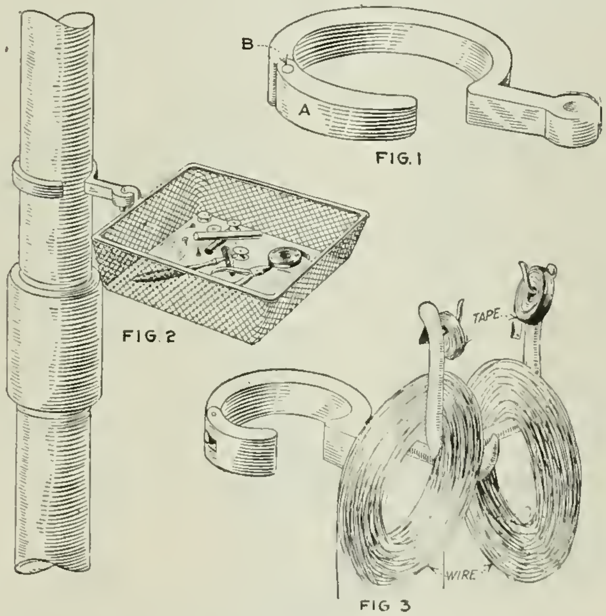
Recently, I had a new man on the midnight to 8 o'clock shift. He had specific instructions what to do and how to manipulate the pumps in case they lost the oil, and was told to call me in case of trouble. One morning about 3 o'clock the pump lost the oil and the man evidently lost his head altogether, for when I got to the plant the fire was out and the steam down to 20 lb. The dampers were wide open, allowing a cold draft through the boiler. The engine was running with full load on, though at such reduced speed that the lights could barely be seen. I shut down the engine, closed the damper and cut out a live-steam heating circuit. By this time the steam was down to 15 lb. I started the spare pump, which was in perfect condition, but the steam was too low to run the pump fast enough to pick up the oil. The case seemed hopeless. There was no means of raising steam except with oil and steam of at least 30 lb. pressure was required to pump the oil. It was very cold and impatient inquiries were coming in thick and fast; so I disconnected the pump suction pipe, put in a tee, then a nipple and valve, and in the valve I screwed a piece of 3-in. pipe about 3 ft. long. I then attached ropes to two pails, and with these we drew oil from the tank, carried it to the boiler room and filled the suction line and pump through my improvised standpipe. By that time there was only 10 lb. of steam pressure, barely enough to move the pump and atomize the oil in the burner. I certainly felt relieved when the gage on the oil line to the burners showed pressure enough to start the fire. We kept carrying oil until we had 40 lb. steam and succeeded in getting the pump to take oil from the tank. In an hour from the time I arrived we had the full load on the engine and steam heat on in all departments.

This incident convinced me that in all oil-burning plants the burner pump should take oil from an overhead tank, so I am installing a small overhead tank to be kept filled by piping the discharge oil from the over-pressure valve, on the oil line between the pumps and burners. From this overhead tank I will run an overflow pipe to the storage tank instead of the present layout where the overflow pipe runs directly back to the storage tank. From the bottom of this auxiliary tank I will run a pipe to the pump suction line so that it will only be necessary to open a valve to prime the pump, since the overhead tank will always be kept full by the discharge from the overpressure valve.

Ash Fork, Ariz. W. G. Camp.

Easily Attached Toolholder

The bracket shown in Fig. 1 is made of machine steel and hardened on the corners for gripping on pipes or poles for holding the tool basket, Fig. 2, or the wire and tape holder, Fig. 3, thus enabling the electrician to have everything within easy reach. The part *A*, Fig. 1, is hinged to give access to the pipe or pole. The rivet *B* is made tight enough to keep the part *A* closed when the bracket is in place. M. P. Bertrande.



FIGS. 1 TO 3 PARTS AND ASSEMBLY OF TOOLHOLDER

Ozone Park, N. Y.

A Suggestion to Advertisers

Although the pages of *Power* are interesting from the front to the back and are full of useful information, there is one thing more your advertisers might do (some do it now but others do not); that is, to mention their representatives in the principal Canadian cities. We have often written to advertisers only to be referred by them to a firm within a hundred miles of here.

Granby, Que., Canada. J. Drummond.

Starting Synchronous Motors

In Mr. Gray's article, "Starting Synchronous Motors," in the Mar. 12 issue of *Power*, it is stated that when an attendant was not at hand to help the operator put the motor in service he tied the starting lever on the compensator in the starting position and then threw in the oil switch at the switchboard.

Some time ago I worked in a plant where there were two large synchronous motors with a similar starting equipment to that described by Mr. Gray. In starting the machines, we first closed the oil switch at the switchboard and then went to the compensator and threw it to the starting position. When the motor had come up to speed, the compensator was closed to the running position, after which the operator went to the switchboard, closed the field switch and made the necessary adjustments.

This may not be any better way of starting the motor than Mr. Gray's, but it seems to be somewhat simpler. D. G. Simmons.

Beaver, Penn.

Snifting Valves on Pumps

By inference from the letter by A. L. Haas, on page 410 in the issue of Mar. 19, it would seem that it is the practice in England to fit snifting valves to pumps of all kinds to admit a small amount of air at each suction stroke. If this is the case, I am wondering what effect is observed in the boilers from this introduction of air. We are in the habit of believing that air (oxygen) in water is a fruitful cause of pitting in pipe systems and boilers, and often considerable trouble and expense are incurred in eliminating it, as against this deliberate introduction. Then again, if the plant is operated condensing, the extra air has to be got rid of from the condenser at the cost of power, not to mention the other mischief it does.

If the entrained air is drawn out at the air chamber or elsewhere before it gets beyond the pump, it would seem to be a useless expenditure of power to compress any small amount of air and then discharge it. Surely, a pump should operate right without snifting valves.

New York City. J. Lewis.

Compressed Air for Cleaning Motors

In the issue of *Power* for Mar. 12 appeared an article by D. R. Shearer, on "Compressed Air for Cleaning Motors." The following on the same subject, but on somewhat broader lines, may be of interest. As it is often necessary to clean equipment carrying potentials of 2300 volts and lower, it is advisable to safeguard the operator as well as the apparatus. The nozzle of the cleaning tool should, therefore, if of metal, be well insulated with cambric and friction tape, otherwise short-circuits may occur between ground and live parts or live parts of opposite polarity. In any case the operator may be subjected to danger of shocks. A nozzle made of one of the insulating compounds now on the market is satisfactory, but should have a metallic lining on account of the erosive effect of high-velocity air.

An air line should be allowed to blow off for several minutes before the nozzle is placed near the insulation. There is usually oil and dirt and often water in the tank or pipe line, and if this is not blown out into the air it may be blown into the insulation of the machine, covering the windings with oil and dirt, both of which are conducive to short-circuits and grounds. The dirt, moreover, at high pressures such as 100 lb. per sq.in. may be forced into the insulation and cause failures.

Mr. Shearer recommends an air pressure of 100 lb. per sq.in. This pressure is too high for most cases, for blowing out rotary converters, generators and motors—a pressure of 60 to 80 lb. is the maximum and should not be exceeded. At 100-lb. pressure, with the nozzle close to the insulation, pieces of grit are easily forced into the insulating materials. On old apparatus or that which has carried heavy loads, the insulation has a tendency to rise up from the conductor, causing air bubbles; high-pressure air blows these open, tends to fray wrappings and may even blow pieces of insulation off entirely, while always tending to crack the insulating varnishes. A pressure above 70 lb. per sq.in., unless the nozzle is held at least 6 in. away from the insulation, is, in my opinion, a dangerous practice.

Every compressed-air tank should be fitted with a pressure gage and a safety valve. The air pressure should preferably be automatically controlled; that is, the air compressor should automatically shut down when the safe working pressure is reached.

Where 500-volt direct current is available, as it is in all rotary-converter railway substations, I have used discarded air compressors from street cars. These outfits occupy about one foot in height and a floor space of about one and one-half by two feet. They are automatically controlled, and the series motor is started direct from the line without the complication of starting resistance.

These sets, although small, answer the purpose for an 8000-kw. station provided a fairly large tank is used. are economical of space and are of low cost.

Chicago, Ill. R. K. Long.

License Internal-Combustion Engine Operators

I am a licensed steam engineer and machinist, and also run gas and oil engines and have had several years' experience in testing, erecting, etc., in the gas- and oil-engine business. It has often occurred to me that there should be some way provided for gas engineers to secure a license that would show their proficiency. It seems to me that it would be profitable to all concerned, when understood. The engineers would get their license and possibly more pay, and last, but not least, the employers would know how to get competent men.

The safety departments do not seem to think it necessary to license gas-engine operators, but these men should know as much about lining up engines, setting valves, adjusting bearings, etc., as the steam engineer. I believe that there are a large number of operators that would be glad to avail themselves of such an opportunity. I would like to have an expression of opinion on this matter from the readers of *Power*.

Philadelphia, Penn. T. A. Marshall.

Accident to Turbo-Alternator

We have been hearing considerable about turbine and turbo-alternator failures during the last year or so. The following is a description of a peculiar accident that happened to a 2000-kw. 3600 r.p.m. 2200-volt two-phase alternator, causing a heavy explosion and completely burning out the field and armature windings of the machine. One of the steel end shrouds on the rotor became loose and worked endwise sufficiently to allow the ends of the brass wedges in the slots to bend out by centrifugal force and cut through the winding of the stator. From all appearances the cutting of the armature coils was gradual and no damage was done until one of the wedges was broken off and thrown into the windings, this doing the final damage. There appeared to be two explosions coming very close together, probably caused by one phase winding being short-circuited slightly before the other. The figure shows how the end shroud *C* worked endwise, allowing the brass wedges *A* to bend out by centrifugal force and finally break off and fly into the stator winding. *B* and *B* are small screws that were threaded into the polepieces to help hold the ring in place.

Improvement in Boiler Economy

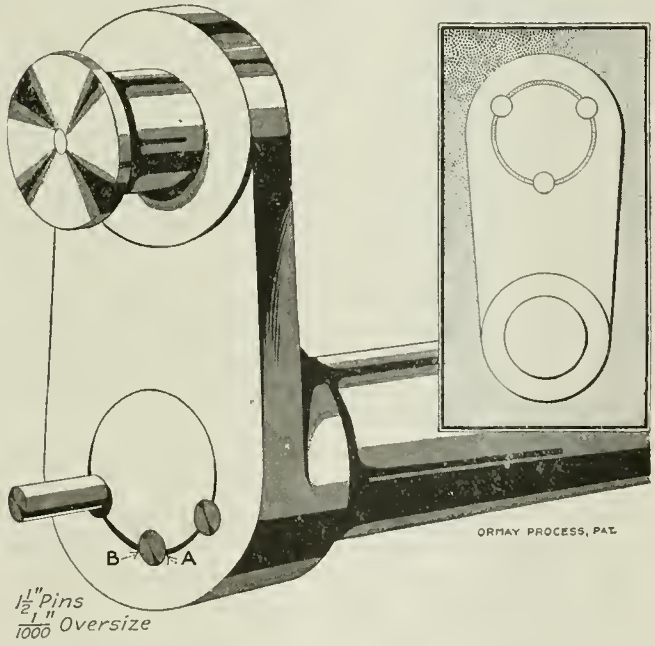
I am not an engineer, only a boiler operator, but the following may be of interest to readers of *Power*. I once had charge of three return-tubular boilers for over four years. When I took charge of them they were burning from eight to nine tons of coal a day on the high-pressure boiler and eight tons on the low-pressure boiler, only two in operation at a time in the winter season. I got busy trying to improve things after looking the situation over. The boiler settings were full of air leaks. In the back end you could throw a dog through, and there was no insulating covering on the boiler tops and no way to clean the tubes. Inside they were coated with scale from ⅛ to ¾ in. thick.

I went to the general manager and told him if he would permit me to make some changes it would make a large saving in coal. He told me that if I could do anything to save coal to "go to it" and that he would get me whatever was needed. I relined the fire wall in the fireboxes, put in new door frames and new grates and patched up the other parts of the boiler settings. We got a new feed pump, and I made a tight wooden top for the water tank and piped the pump exhaust into the tank, and the returns from all steam lines were also piped back to the tank. They had been running into the sewers for years. This was a big saving for we used city water through a meter. I then got busy inside of the boilers with a pick and hammer and got rid of the scale, so I made a saving of eight tons of coal a day, and the whole thing cost only $250, feed pump and all. M. V. B. **Potts.**

Massillon, Ohio.

Fastening a Loose Crank

On page 264 in the issue of Feb. 19 there are illustrations, at the lower part of the page, of what I, and others, consider the wrong method of trying to make a loose crank tight; for it is plain that the looseness of the crank is divided all around the shaft (purposely shown exaggerated in the illustration) and that the taper pins have the load and strains to carry. In other words, the shaft supports the pins and the pins the crank; while, if the job was done as shown in the illustration herewith, the lost motion or looseness would be taken up all in one direction and the crank would fetch up against the shaft for nearly half of its circumference, would have a perfect grip and would retain the original alignment; and the pins would only be called on to hold it in position. I have fixed several in this way and none that I have heard of has worked loose. I have also refitted two that someone had pinned all the way round. I do not make taper holes or pins, but make the pins about one-thousandth of an inch larger than the holes, and drawfile them on two sides at the points *A* and *B*. I pack the pins in ice before driving, but do not always heat the crank. I make the pins about three inches longer than I expect to use, mark the point on them to show when they are "home" and also make some sort of vent to let the air out of hole. I do not grease the pins, but drive them with a battering ram made of a piece of shaft hung by a rope block.



LOOSE CRANK PINNED ON ONE SIDE ONLY

Exeter, N. H. L. **Johnson.**

Watch Your Step!

During the last quarter of a century much has been said and done in the field of industrial management, and the managerial mechanism developed has proved beyond doubt that it is nothing but a mechanism and as such may or may not produce the desired results, depending on how and by whom this mechanism is used. The management of power plants drags in the tail of the procession probably for two reasons: First, belief in the fallacy that good equipment necessarily produces good results; second, because financial interests consider the cost of power an insignificant item of the total expense. When, however, we feel the pinch of the shortage of fuel and when this shortage not only enhances the cost of power, but endangers the very existence of the various industries, even the health and well-being of communities, these fallacies must be disposed of at once.

It is not the equipment and supplies that produce results, but the mode of their use. When this is realized, two problems present themselves to power engineers: First, to secure mechanism for modern management; and, second, to make proper use of it. The success of a managerial mechanism involves certain responsibility by plant owners, since it is obviously their task to provide the plants with the means to study the causes and effects, to standardize and to keep adequate and dependable records. This in turn involves the education and training of the employees to make proper use of the available knowledge. Furthermore, they must have permanent and sufficient incentive for learning and living up to the better way taught them by the expert management. Under such conditions the executive is relieved of all the worries as to routine details, as these are standardized and can be well taken care of by subordinates. The major part of the time of the executive may thus be devoted to solving special problems and inaugurating improvements.

The results accomplished in the plants that have adopted these principles are permanent since they are worked out from the bottom up, and the economy accomplished varies all the way from 15 per cent. to 50 per cent., depending upon the conditions originally found in the plant.

To meet the present contingency both as to men and fuel, the first thing to do is to put the house in order after a thorough study, so that the methods may be based on facts, not on opinions and traditions. When this is done, enough room will be found in which to build up efficiency without resorting to "better equipment" and a lot of patent cures.

New York City. WALTER N. POLAKOV.

The Engineers' Unions

I have read with interest the few letters which have "passed the censor" and have been published in *Power* recently, in regard to engineers' unions, and wish to express, briefly, a few of my sentiments on the subject. I have been a member of one such union for years and must disagree with the statement by Mr. Dye, in the issue of Jan. 1, 1918, that anyone can get into the union and suggesting that candidates be examined.

Before I was accepted, I was required to produce my license to prove that I was an engineer, and in order to get that license I had to undergo a rigid examination. The possession of that paper was good evidence that I was an engineer without the necessity of any further examination on the part of the union, but I was also examined orally by a committee in a thoroughly practical way.

Personally, I have never been directly benefited through being a member of the engineers' union, but indirectly I have, as I am in the Federal service and it is a fact that it was primarily due to the activities of union labor among the Senators and Congressmen that Congress was induced to pass the eight-hour law, which limits the hours of labor of Government employees to eight hours in twenty-four, with one day off in seven and an annual vacation and sick leave on full pay. At present union labor is working very hard for a substantial increase in the wages of Government employees to offset in part the increased cost of living, and from all indications it will be granted. This will affect engineers as well as other employees in the Government service.

The Government as an employer does not recognize unions as an organization except in a few cases such as the navy yards. It is a fact that the lower-paid Government employees, clerks and mechanics who were until a year or two ago unorganized, had not had an increase in wages for many years until Congress in 1917 granted a temporary increase of from 5 to 10 per cent. for one year only, an inadequate increase in the face of the present conditions. But largely owing to the activities of the Federal Employees' Union coöperating with the heads of the various departments, a bill has been introduced in Congress to grant an increase of from 30 per cent. on the salaries less than $1000 to 5 per cent. on salaries up to $2500 per annum, in consideration of the present high cost of living.

Referring again to the engineers' case, if there are no state laws requiring engineers to take an examination and secure a license to operate a plant, or where existing laws are lax, the union naturally can demand further evidence or examination, and to rectify this matter every engineers' organization, union or not, as well as trade organizations should demand more rigid license laws where they are not up to the recognized standard required in Massachusetts, Ohio and some other states.

It must be admitted, however, that there are isolated cases where some individual member has used his influence with the union to hold a position which he otherwise might not be able to hold, but these cases are rare and should be eliminated. On the other hand, the unions certainly have been instrumental in securing uniformity in the scale of wages for engineers in the same localities, doing the same class of work.

Columns could be written setting forth the advantages and disadvantages of unions, but having in mind the editorial in *Power* recently and the editor's reluctance to allow anything of this sort to "pass censor," I can only say that the motto of "Learn more, earn more" should be changed to read, "To earn more, learn more and take the necessary steps to see that you get it." To which end the engineers' union will be found of great assistance. J. C. HAWKINS.

Hyattsville, Md.

Inquiries of General Interest

Compensating Variation from Scale of Planimeter—How is a planimeter used for measuring the mean effective pressure shown by an indicator diagram made with a 16-lb. spring where the planimeter scale is intended to show m.e.p. for a 30-lb. spring? C. L. J.

Operate the planimeter as though a 30-lb. spring had been used and take 16/30 of the result.

Air-Space Walls for Boiler Settings—What is the advantage of air space, or cavity walls, for boiler settings? A. R. W.

An air space acts as a nonconductor for retarding loss of heat from radiation, and when cavity walls are properly designed and constructed, the spreading of the material adds to the strength and stability of the setting. If the outer walls are stayed to the inner walls by good forms of slip and expansion joints, the outer wall will be little affected by expansion and contraction from changes of temperature causing cracks for infiltration of excess air with detriment to furnace economy.

Angle of Advance with Negative Lap—When a D slide valve has negative steam lap, will the eccentric require positive or negative advance to close the steam port before the end of the stroke? T. J. M.

With negative lap the valve has the port uncovered during more than one-half a revolution of the shaft, and if the eccentric should be set at 90 deg. with the crank, the port would be uncovered both at the beginning and at the end of the stroke of the piston. Hence to have the port covered before the end of the stroke the eccentric must have positive advance, that is, must be set ahead of the 90-deg. position, which also would increase the lead or port opening at the beginning of the stroke and hasten all of the valve events

Single Shear and Double Shear—What is meant by a boiler rivet being in single shear or in double shear? F. A. P.

A rivet is said to be in single shear when it is subject to shearing action that tends to produce cleavage at a single cross-section of the rivet, as when used in a riveted lap-joint for holding together two plates that pull in opposite directions. A rivet is said to be in double shear when subject to shearing action that tends to produce cleavage at two cross-sections of its length, as when the rivet is used in a riveted butt-and-double-strap joint for holding together a main plate, sandwiched between an inside and outside cover plate whose direction of pull is opposite to that of the main plate.

Height of Pumping Water—A direct-acting steam pump with steam piston 12 in. diameter and water piston 8 in. diameter is operated with steam at 110 lb. per sq.in. gage pressure. To what height in feet can the pump raise water, assuming 70 per cent. efficiency? G. G. M.

If the total pressure exerted on the steam piston is transmitted to the water piston, 110 lb. per sq.in. gage pressure acting on the steam piston, opposed by back pressure of the atmosphere, would exert a pressure of $(12^2 \div 10^2) \times 110 = 158.4$ lb. per sq.in. on the water piston; one foot head of water exerts a pressure of 0.433 lb. per sq.in., and without friction of water in the pump or pipes the pump could raise the water to a height of $158.4 \div 0.433 = 365.8$ ft. above the level assumed by the suction water under atmospheric pressure. With 70 per cent. efficiency the height would be 0.70 of $365.8 = 256$ feet.

Transmissive Capacity of Steel Shafting—What is the rule for estimating the approximate horsepower-transmitting capacity of the ordinary sizes of steel shafting? S. M.

The approximate number of horsepower capable of being transmitted with safety by ordinary sizes of turned steel lineshafting, when well supported, with pulleys near to the bearings and with the hangers so spaced that the deflection will not exceed 0.01 in. per foot of span, is equal to the cube of the diameter of the shaft in inches for 100 r.p.m. and directly in proportion for other speeds. The safe load for head shafts may be taken as 75 per cent. and for bare transmission shafts as 175 per cent. as much as for ordinary line shafting. Cold-rolled shafting may be taken as one-third stronger than turned steel shafting.

Guarantee Test of Oil Engine—How would a test be made of the guaranteed oil consumption of a 40-hp. oil engine running a 25-kw. 220-volt direct-current generator used for lighting? H. P. K.

To make the test conclusive the economy and regulation should be determined as nearly as possible for the different loads, speeds and other conditions specified in the guarantee. If constant loads of the given magnitude are not obtainable supplying power to the regular load circuit, the desired loads can be obtained by use of a temporary water-rheostat such as illustrated and described on pages 180 and 181 of Aug. 7, 1917, issue of *Power*. If the generator is not to be included in the guarantee, it will be necessary to take into account the efficiency of the generator at the different test loads. These data are generally obtainable of the manufacturer. For reliable results each test should run for a period of at least three hours, noting the weight, kind, source, and analysis of oil used; and readings should be taken at five-minute intervals of the speed of the engine and of the volts and amperes of electrical output. For any test period the average (volts × amperes) ÷ 1000 will be the average kilowatt output, and the number of pounds of oil used per hour divided by the average kilowatts generated will be the oil consumption per kilowatt-hour.

Placing New Piston Rod in Engine—In putting in a new piston rod to replace an old one on a simple engine with V-shaped guides, what is the proper method of centering the rod? J. K.

In providing a new piston rod, the centering of the rod with the stuffing-box is likely to become misplaced. First of all, extend a line through the center of the cylinder past the guides and determine whether the faces of the guides are parallel with the cylinder center line, for that purpose measuring from the cylinder center line to a short round shaft or mandrel, placed in the V of the guide, and of suitable diameter to touch the sides of the V at about the middle of the wearing surfaces. If not parallel, the guides need to be made so by adjustment or as a repair or alteration of the engine. When the guides are parallel to the engine center line, place the new piston rod in the piston and with the piston in the crank end of the cylinder and the end of the rod parallel with the guides, adjust the packing rings so the rod will be in the center of the piston-rod stuffing-box. Then put the crosshead in place with necessary adjustment of the crosshead slippers to make the piston rod parallel with the guides when the rod is connected to the crosshead. If all adjustments have been properly made, the rod will travel centrally through the stuffing-box. If it does not, the vertical and horizontal adjustment of the crosshead should be made so there will be no movement of the stuffing-box gland when the engine is running, otherwise the rod will become scored and it will be difficult to make the packing hold tight.

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Power Plants of Modern Ships

By ESKIL BERG

For the power plants of modern ships turbo-generators are built with an efficiency of over 80 per cent., which, with motors of 95 per cent. efficiency and boiler efficiency of 80 per cent., produce a shaft horsepower-hour with 0.825 lb. of coal of 14,000 B.t.u. Six new battleships for the Navy, requiring 33,000 hp. each and five large battle cruisers requiring 180,000 hp. each will be electrically driven. Steam consumption of 11.1 lb. per shaft horsepower-hour is guaranteed for the new battleship "New Mexico," which will be driven electrically.

IN a paper, "Propulsion of Ships," by Eskil Berg, engineer, General Electric Co., Schenectady, N. Y., before a joint meeting of the electrical section of the Franklin Institute and the Philadelphia Section, American Institute of Electrical Engineers, the following interesting figures were given relative to the power plants of modern ships; the abstract is from the March *Journal* of the Franklin Institute.

Speaking of the cautious advance in marine engineering, Mr. Berg said: Some of the Hudson River boats still have side wheels and use boilers with about 30-lb. steam pressure, producing a brake horsepower with about 30 or 40 lb. of steam. Steam engines were built as early as 1765, but it was not until 1807 that one was used to propel a boat. Electricity was used for power transmission as long ago as 1876, but its application as a medium for transmitting power to the propeller of a ship did not take place until 1908. This goes to show that progress in marine propulsion is very slow, the tendency being to follow the old and beaten paths.

The turbine is preferable to the reciprocating engine as a prime mover for ships, because it gives simple rotation and admits the possibility of a large range of expansion. At present the best steam engines are the triple and quadruple-expansion types; but on account of the size of the low-pressure cylinder an expansion ratio of more than 16 to 1 or 20 to 1 is not possible. In the turbine, however, there are practically unlimited possibilities of expansion, depending almost entirely upon the temperature of the condensing water. A vacuum of 29 in. is not at all unusual, and 29.5 in. is being recorded in some of the large central stations during the winter months. What this means may be better understood when we consider the available energy of a pound of steam when expanded from boiler pressure to various degrees of vacuum.

200-lb. pressure to 24 in. vacuum, 220,000 ft.-lb.
200-lb. pressure to 26 in. vacuum, 238,000 ft.-lb.
200-lb. pressure to 28 in. vacuum, 265,000 ft.-lb.
200-lb pressure to 29 in. vacuum, 289,000 ft.-lb.

In other words, a turbine can realize about 25 per cent. more in the energy of steam than the reciprocating engine, which means a saving of about 25 per cent. in fuel, boilers, etc.

Turbines, when used for direct connection to the propeller shaft, must necessarily be designed to operate at a speed that is too low for the economical use of steam, and even then cannot be conveniently designed for a speed low enough to secure efficient propeller action. Sir Charles Parsons realized this and advocated the use of direct-connected turbines only for high-speed ocean liners requiring a large amount of power, and the "Mauretania" is probably one of the best examples of ships using this method of propulsion. The horsepower of the "Mauretania" is 68,000, the speed about 26 knots, and about 23.5 tons of coal per hour is required. The water rate obtained is about 11.5 or 12 lb. and the coal consumption about 1.5 lb. per shaft horsepower-hour.

Three years ago, when the White Star Line decided to build the "Olympic" and the "Titanic," which were slow-speed ships requiring about 25,000 hp., Mr. Parsons advocated a combination of two reciprocating engines exhausting into a low-pressure turbine, which gave an economy about comparable with the "Mauretania."

The steam engine is an efficient prime mover when operating at the higher temperature ranges; that is, an engine may have as high as 80 per cent. thermodynamic efficiency when operating from boiler pressure to atmosphere, whereas if it was operated down to a 28-in. vacuum, the efficiency would not be greater than 40 or 50 per cent. On the other hand, the turbine works efficiently in the low-pressure end of the cycle, so that by using a reciprocating engine in the upper ranges in combination with a turbine to utilize the turbine in the low-pressure ranges, an over-all efficiency is obtained which may be above that obtainable with either the reciprocating engine or the turbine when working alone. In the "Olympic" all reversing and maneuvering is done with the reciprocating engine, making it possible to build a simple and efficient low-pressure turbine.

With electric transmission, high steam pressure and superheat can be used, and the gain in fuel economy by its use has proved to be very appreciable. A steam temperature of 700 deg. F. is now successfully used in Europe, which, with 500-lb. steam pressure, would give 223 deg. F. superheat. The heat available for work would then be about 36.3 per cent., whereas under ordinary steam conditions with 200 lb. pressure and 50 deg. superheat, you would have only 30.75 per cent. available and a gain of 18 per cent. in fuel, which would more than compensate for any additional weight or cost of the electrical equipment.

Shaft Horsepower on 0.825 Lb. Coal

Turbo-generators are now built with an efficiency of over 80 per cent. which, with motors of 95 per cent. efficiency and a boiler efficiency of 80 per cent. would produce a shaft-horsepower-hour with 0.825 lb. of coal, containing 14,000 B.t.u. per lb. or 0.61 lb. of oil of 19,000 B.t.u. per lb., the latter figure comparing favorably with Diesel engines when lubricating oil is taken into consideration.

Owing to the wonderfully fine performance of the collier "Jupiter," which has now been in service for about four years, the Navy Department decided to install electric propelling machinery in the battleship "New Mexico," which is now nearly completed in the New York Navy Yard, and the apparatus for which has recently passed all Government tests at the Schenectady works of the General Electric Co. The Navy Department has also decided to install electric propelling machinery in six other new battleships, requiring about 33,000 hp. each and in five large battle cruisers requiring 180,000 hp. each.

The third instance of electric propulsion is the battleship "New Mexico." This installation provides conditions where the advantages of electric propulsion can be realized. The "New Mexico" is the largest and most powerful battleship that has been laid down by our Navy up to the present. She will have a displacement of 32,000 tons and a designed speed of 21 knots, requiring about 28,000 hp. The propelling machinery is, however, designed to deliver a maximum of 37,000 hp., and it is believed that this will give her a speed of 22 knots.

The equipment will consist of two turbo-generating units, four propelling motors (one for each shaft), switching apparatus, cables, instruments, etc. The contract also calls for two 300-kw. noncondensing direct-current turbo-generators, which will furnish excitation and power to drive the auxiliary machinery. As the General Electric Co. was required to guarantee the steam consumption of the propelling machinery, including that of the auxiliary, the greatest care was taken in their selection, and they are all to be electrically driven. The exhaust steam from the direct-current generating sets, operating noncondensing, will be used for heating the feed water, and steam that may not be required for this purpose will be exhausted into the main turbine. The generators for the "New Mexico" are bipolar alternators, and the motors are arranged to be connected for either 24 or 36 poles. For economic cruising at a speed of 15 knots or less, only one generating unit will be required with the motors on the 36-pole connection. For higher speed the 24 polar motor connection will be used with both generators One generator, however, will be capable of driving the boat up to a speed of about 19 knots.

The steam-consumption guarantees as made to the Government cover the total amount of steam used by both the main generating units and the auxiliaries, and are as follows:

Steam pressure 250 lb. gage at the throttle
10 knots, 14.6 lb. per shaft. horsepower-hour
15 knots, 11.4 lb. per shaft horsepower-hour
19 knots, 11.1 lb. per shaft horsepower-hour
Maximum speed, 11.9 lb. per shaft-horsepower-hour

Very heavy penalties are attached to the guarantees in case they are not met; namely, $25,000 per lb. for the two lower speeds and $20,000 per lb. for the two higher speeds.

To be able to correctly judge the relative economy of different methods of propulsion, it may be interesting to compare the water rate per effective horsepower, taking for example such different methods as the battleships "Florida" and "Utah," which are equipped with Parsons turbines; the "Delaware," which has reciprocating engines; and the "New Mexico" with electric drive:

	Propeller Speed	Water Rate per Effective Horsepower per Hour		
		12 Knots	19 Knots	21 Knots
Florida	328	31.8	24.0	23.0
Utah	323	28.7	20.3	21.0
Delaware	122	22.0	18.7	21.0
New Mexico	175	17.3	15.0	16.4

That electric propulsion can be profitably applied to a small boat is proved by Mr. Ljungstrom, of Sweden, in the case of the small coastwise steamer "Mjolner," which is only 225 ft. long, 56 ft. beam and 15 ft. draft, requiring 900 hp. Two sister ships were built, namely, the "Miner" and the "Mjolner." The former was equipped with triple-expansion engines and Mr. Ljungstrom guaranteed a saving of 30 per. cent. in fuel in his method of electric propulsion in the "Mjolner" over the "Miner," equipped with engines. The boats have now been built and tested and the electrically driven boat showed a saving of 42.3 per cent in fuel consumption. This is indeed a remarkable record, but might be partly explained by the increase in efficiency of the boiler plant. For this electric drive Ljungstrom uses 218 lb. steam pressure and 235 deg. superheat, and this alone would effect a saving in coal over the "Miner" of about 15 per cent.

Emergency War Training

Emergency War Training for Gas-Engine, Motor-Car and Motor-Cycle Repairmen, is the title of Bulletin No. 10, recently issued by the Federal Board for Vocational Education, Washington, D. C. This bulletin contains 78 pages and gives an outline and suggestions for courses designed to train men to repair motor-trucks, motor-cars, motorcycles and airplane motors. As pointed out in the foreword:

> There is a critical and constantly growing need for many thousands of mechanics and technicians for army occupations carried on in and behind the lines of the United States Army. Many of these workers, already experienced in similar occupations of civil life, will be secured through the draft, and possibly through voluntary enlistment. It is recognized by those in a position to know, that the quota thus gained will not be sufficient and that it will be necessary to train many thousands of men in various ways for various occupations. The War Department has taken definite steps to provide for this training systematically through army schools, in some instances at cantonments, but largely at the industrial, trade and engineering schools of the country.
>
> For some months the Federal Board has been making intensive investigations and studies of the demands of these army occupations. A series of bulletins for the guidance of those giving this training has resulted from these studies. The courses and methods suggested in these bulletins have been carefully checked by experienced army officers and represent the consensus of opinion as to what training should be given and how it should be given.

Bulletins thus far published are: No. 1, Statement of Policies; No. 2, Training Conscripted and Enlisted Men for Service as Radio and Buzzer Operators in the United States Army (International Code); No. 3, Emergency Training in Shipbuilding—Evening and Part-Time Classes for Shipyard Workers; No. 4, Mechanical and Technical Training for Conscripted and Enlisted Men (Air Division, United States Signal Corps); No. 5, Vocational Rehabilitation of Disabled Soldiers and Sailors (also printed as S. Doc. No. 166); No. 6, Training of Teachers for Occupational Therapy for the Rehabilitation of Disabled Soldiers and Sailors (also printed as S. Doc. No. 167); No. 7, Emergency War Training for Motor-Truck Drivers and Chauffeurs; No. 8, Emergency War Training for Machine-Shop Occupations, Blacksmithing, Sheet-Metal Working and Pipe Fitting; No. 9, Emergency War Training for Electricians, Telephone Repairmen, Linemen and Cable Splicers; No. 10, Emergency War Training for Gas-Engine, Motor-Car and Motor-Cycle Repairmen; No. 11, Emergency War Training for Oxyacetylene Welders; No. 12, Emergency War Training for Airplane Mechanics—Engine Repairmen, Woodworkers, Riggers and Sheet-Metal Workers; No. 13 (Agr. Ser., No. 1) Agricultural Education—Organization and Administration.

Persons desiring to secure copies of any or all of these bulletins can readily do so by applying to the Federal Board for Vocational Education, Ouray Building, 805 G Street, N. W., Washington, D. C.

Consolidation of Power Companies Proposed

There is on foot a proposition to consolidate the hydroelectric power companies at Niagara Falls. This is at the request of and in coöperation with the War Department as a necessary war measure to provide sufficient electrical energy for war industries in and about the City of Buffalo.

The companies to be consolidated are the Niagara Falls Power Co., the Hydraulic Power Co. and the Cliff Electric Distributing Co. If carried out, this consolidation will call for an expenditure of about $15,000,000 for the construction of an additional plant and equipment, whereby it is hoped to increase the output by 170,000 hp. above the amount now being generated by the independent operation of these companies.

Engineers are also occupied with the proposed power coördination plans of Dr. Garfield, and they, representing the utility interests throughout the United States, are working out rates for transmission line for tying in and estimating of costs.

Fuel and water-power experts are considering linking up the Lehigh Coal and Navigation plants at Lansford and Hauto with the Philadelphia Electric Co. in supplying power to Hog Island, League Island, Eddystone, Westinghouse, Bethlehem, Midvale and all other large industrial establishments.

Moreover, there is a possibility that three or more power plants of 100,000 hp. will be erected at other points in the anthracite region to supply energy to other industrial establishments throughout Pennsylvania so as to link up a chain of such units which would afford a better supply for munition work.

It is also understood that plans are contemplated for linking up power-generating plants from New England to the District of Columbia in units that will be able to supply transmission facilities with a view to affording relief when difficulties may incapacitate the service at any section. This would prevent the crippling of power and lighting circuits which might occur due to one cause or another.

Modifications of Coal Prices

Owing to a reclassification of the coal fields in several districts in West Virginia, in part of Kentucky, and in the coal-mining districts of Missouri, Kansas and Virginia, the selling prices of some coals are slightly changed. The new prices, which are now effective, are as follows:

State	Run-of-Mine	Prepared Sizes	Slack or Screenings
West Virginia:			
No. 10 district: Coal and coke and Gauley districts; Taylor, Barbour, Lewis, Buckhannon, Randolph, Gilmer, Braxton, Webster, and Greenbrier Counties; operations in Nicholas County east of the mouth of the Meadow Branch of the Gauley River and coal and coke district in Kanawha and Clay Counties north of Charleston	$2.30	$2.55	$2.05
Fairmont district: Monongalia, Marion and Harrison Counties	2.15	2.40	1.90
Thacker district: Operations in McDowell County west of Panther on the Norfolk & Western and in Mingo County west along the Tug Fork of the Big Sandy River to Williamson on the Norfolk & Western	2.30	2.55	2.05
New River district: Fayette County south of Hawk's Nest on the Chesapeake & Ohio and Fayette and Raleigh Counties south of Paintsville on the Virginian Railroad and Wyoming County north of Herndon on the Virginian Railroad	2.35	2.60	2.10
Logan district: Logan County and operations in Boone County south of Danville on the Chesapeake & Ohio and Lincoln County south of Gill on the Chesapeake & Ohio	2.15	2.40	1.90
Putnam County	2.50	2.75	2.25
Kenova district: Operations on the watershed of the Tug Fork of the Big Sandy River west of Williamson on the Norfolk & Western, and Wayne County	2.30	2.55	2.05
Kanawha district: Nicholas County west of the mouth of the Meadow Branch of the Gauley River, Fayette County west of Hawk's Nest on the Chesapeake & Ohio, and north of Paintsville on the Virginian Railroad, and operations in Raleigh and Boone Counties on the watershed of the Clear Fork Pranch of Coal River, Boone County, north of Danville on the Chesapeake & Ohio, Kanawha County south of Charleston, and Lincoln County north of Gill on the Chesapeake & Ohio	2.25	2.50	2.00
Kentucky:			
Thacker district: Operations in Pike County on the watershed of the Tug Fork of the Big Sandy River east of Williamson on the Norfolk & Western Railroad	2.30	2.55	2.05
Kenova district: Operations in Pike County and Martin County on the watershed of the Tug Fork of the Big Sandy River west of Williamson on the Norfolk & Western Railroad	2.30	2.55	2.05
Missouri:			
District No. 1: Audrain, Bates, Calloway, Henry, Johnson, Monroe, Randolph, Ralls, St. Clair, Schuyler, Vernon and Montgomery Counties, Adair County, except operations of the Star Coal Co., and Macon County, east of New Cambria and mining operations not covered by other rulings	2.70	2.95	2.45
District No. 2: Boone, Clay, Cooper, Chariton, Carroll, Dade, Harrison, Linn, Lafayette, Putnam, Ray, and Sullivan Counties and Macon County west of New Cambria and the long-wall thin-seam mines in Randolph County	3.15	3.40	2.45
Grundy County: Operations of the Star Coal Co., in Adair County and shaft workings in the Lightning Creek or upper thin vein in Barton, Bates, and Vernon Counties	3.65	3.95	2.45
Platte County	3.40	3.65	2.45
Kansas:			
Cherokee and Crawford Counties, except shaft mines in Lightning Creek or upper thin vein and any mining operations in the State not covered by other rulings	2.70	2.95	2.45
Shaft workings in the Lightning Creek or upper thin vein, in Cherokee and Crawford Counties	3.65	3.95	2.45
Osage, Franklin and Linn Counties	3.50	4.50	2.80
Leavenworth County	3.40	3.65	2.90
Virginia:			
Mines operated near St. Charles, Lee County, by the Darby Coal Mining Co.; Black Mountain Mining Co.; Virginia Lee Co.; Old Virginia Coal Co.; United Collieries Co.; Benedict Coal Corporation; and the Imperial Mine of the Virginia Iron, Coal and Coke Co., Roanoke, Va.	2.65	2.90	2.40

These prices do not include the allowance to operators of 45c. a ton who have complied with the wage increase agreement.

The Fuel Administration has also issued a ruling on the prices of coal from wagon mines, which are mines that are not located on railway lines, so that the coal must be transported from the mine mouth to the railroad in wagons.

Operators of wagon mines will not be allowed to add the cost of hauling to the Government price when the coal is loaded into open-top cars, except when such coal is bought by a railroad for its own use.

This decision of the United States Fuel Administration affirms the rulings promulgated by it Oct. 6, 1917, under which operators of wagon mines are permitted to make a charge of not more than 75c. in addition to the Government price when delivering direct to the consumer or when loading into box cars.

Representatives of the wagon-mine operators sought to induce the Fuel Administration to make a similar allowance for loading into open-top cars. They based their request upon the claim that congestion of the railroads has been relieved sufficiently to justify the use of open-top cars by wagon mines, and that the cost of hauling was the same whether the coal was loaded into box cars or open-top cars.

Investigation of the situation, however, has satisfied officials of the Fuel Administration that the demand for open-top cars by mines that can load only into that kind of cars still exceeds the supply. Under the circumstances, therefore, it was decided that production would be stimulated best by restricting the allowance for hauling to those wagon mines loading into box cars.

Ammonia Oil Separator Explodes

About 10 o'clock Saturday morning, Apr. 27, a high-pressure ammonia oil separator in the Chicago Cold Storage Co.'s plant at Sixteenth and South State Sts. exploded, injuring ten men. The separator was located between the compressor and the condenser on the roof, on a railroad loading platform adjoining the building. The men working in its vicinity at the time of the explosion were injured, most of them being overcome by the escaping ammonia fumes. It is believed that none of the injuries will prove fatal.

In the plant there are three 175-ton vertical compressors, each with two single-acting cylinders. Each compressor is protected by a safety valve set to blow at 250-lb. gage pressure. Depending upon the load and other operating conditions, the condenser pressure varied from 145 to 180 lb. At the time of the explosion the plant log showed it to be 175 lb. gage, and the suction pressure 2 lb. gage. The suction line to the compressor was 5 in. diameter, which is small for pressures as low as 2 lb. gage. It is quite probable that the vapor came back to the machine superheated, and, in being compressed to 175 lb., the temperature would be abnormally high.

The separator was cast of ferro-iron to a diameter of 16 in. and a length of 42 in. The bottom was convex, while the top head was flanged and fastened to the body by sixteen 1⅛-in. bolts. While no blowholes or flaws in the casting could be detected, it was noticed that the cylinder walls were of uneven construction, the thinnest part of the metal being an inch thick. Assuming 30,000-lb. tensile strength for the ferro-iron, the 16-in. cylinder would carry a safe working pressure of 375 lb. per sq.in., based on a factor of safety of ten instead of the eight generally assumed. It is evident that the separator was fully protected by the safety valve and that temperature rather than pressure was the initial cause of the accident.

Thomas Andresen, cooling-plant inspector for the city, investigated the explosion and advances the following theory as to the cause of the accident: The machines were operated with a low suction and a high condenser pressure. Through a leaky stuffing-box sufficient air may have found its way into the cylinder and, in combining with the evaporated hydrocarbon gas from the lubricating oil, formed a dangerous and explosive mixture which was ignited by the unusually high temperature induced by the superheated state of the incoming vapor and the high condenser pressure. No machine or system was ever built to withstand the instantaneous pressure of a hydrocarbon explosion, and as a matter of course the weakest part gave way first. In this case it was the oil separator.

In an explosion of this kind safety valves are of no avail. The cause of the accident must be laid to the unfortunate conditions that build up while the compressor is apparently operating under normal conditions. Similar explosions have occurred frequently when systems that have been in operation are being tested under air pressure. To avoid these possible air explosions, as they are termed, the new rules issued by the City of Chicago prescribe that when testing any existing plant with air, the pressure must not exceed 100 pounds.

Courses for Training Mechanics and Technicians for the Army

Last February the Secretary of War appointed the Committee on Education and Special Training, charging it with the responsibility of training 90,000 men of the National Army for various technical and skilled work. The army is in need, for example, of motor-truck drivers, airplane mechanics, carpenters and blacksmiths. The selective draft methods proving inadequate to supply this demand, the committee was formed to arrange for intensive training.

Educational plants equipped for handling large numbers of students were obviously the machinery that should be adapted to this work. So rapidly has the committee proceeded that 25 schools are now under contract to take the men, 14 schools have begun their work and 7500 National Army men are under instruction. The number of schools will be increased until 30,000 men can be handled at one time. The courses are of eight weeks' duration and the final lot of 30,000 men (for army needs as planned at the minute) will go to the schools Sept. 1.

In arranging for the work institutions were preferred that could accommodate at least 500 men. The institutions include engineering colleges, universities, and mechanics' institutes, while in one city the public-school system is being used. The number of different courses given at an institution depends on various conditions—the number of students, the character of school equipment, location, etc. One school, the University of Virginia, will specialize on the training of motor-truck drivers and will take 600 men at a time. For the truck-driving courses such automobile equipment will be used as is available, and the Government, in addition, will furnish one army truck for each 20 men.

Army officers will be located at each school, and military drill will be carried along simultaneously with the technical instruction. The technical staff will be supplied by the institutions and, with the army officers, will form a board to direct the administration.

The Curricula used are those outlined for intensive training by the Federal Board for Vocational Education, though the staff at each school is given much latitude in the presentation of the essential matter. At some schools coöperation with the local industries is being arranged, as, for example, in the instruction on rubber vulcanizing at Akron, Ohio. At present the following courses are arranged for: Auto driving and repair, bench woodwork, general carpentry, electrical communication (telephone and telegraph work), electrical work, forging and blacksmithing, gas engines, machine shop, sheet metal.

While the men at the schools are National Army men and come through the draft boards, they volunteer for this special training. The Provost-Marshal-General sends out a call to the boards for men with experience fitting them for the lines in which the training is to be given, and are asked to certify volunteers from their rolls. In other words, the men go to the schools directly from their homes and are not drawn from the cantonments. As a result of this volunteer system a very good grade of men has been secured.

The men are required, in addition to their experience, to have had a common school education—though this is not a hard-and-fast rule. Aptitude and ability to learn are the chief requirements.

In the courses themselves the aim will be to push men along as fast as their abilities warrant. Journeymen machinists, for example, will immediately be put on highly specialized work, such as airplane repairs.

All men are ranked as enlisted privates and are paid accordingly, and, of course, are outfitted by the Government. The schools, as a rule, contract for the housing, feeding and instruction in a lump sum per man, per day, but in some cases the housing and feeding will be done by other parties. In arranging for accommodations the Quartermaster's Department has been of invaluable assistance, furnishing cots and other equipment to institutions having the buildings, but lacking the necessary dormitories and dining-room equipment. All sorts of expedients have been used in places where building space was lacking except for the actual instruction. Armories have been converted, and in several cases fair grounds have been used.

To facilitate the work the country has been divided into ten districts, the institutions in each coming, as to the technical instruction, under the direct supervision of a district director. These in turn are under the direction of the general educational director, C. R. Dooley, formerly of Pittsburgh. The committee itself consists of three army officers, Lieut.-Col. J. H. Wigmore, Lieut.-Col. R. I. Rees and Major Grenville Clark. Assisting them is an advisory board consisting of Hugh Frayne, representing labor, and the following representatives of educational interests; J. R. Angell, the colleges; S. P. Capen, Federal bureau of education; J. W. Dietz, corporation schools; C. R. Mann, schools of pure science; Dean Herman Schneider, engineering schools.

Chicago Engineers Hold Joint Meeting

On Apr. 23, C. F. Kittering, president of the Society of Automotive Engineers, gave a most interesting address on "The Automobile Power Plant." The occasion was the first joint meeting of the Chicago Section of the American Society of Mechanical Engineers with the American Institute of Electrical Engineers and the Western Society of Engineers, and the place was the rooms, in the Monadnock Block, of the society last named. The attendance approximated 250. The interest in the subject and the great success of the meeting generally mean that there will be more of them and that active sectional coöperation is in sight.

A. D. Bailey, president of the Chicago Section of the American Society of Mechanical Engineers, presided. In his talk, Mr. Kittering explained very simply the construction and working of the internal-combustion engine, his remarks applying primarily to the four-cycle type. He discussed carburetion, gas feeding, ignition, and gave an elementary conception of fuels and their action in burning. Best of all, he refuted the pessimistic press reports of the airplane situation and reacclaimed the Liberty motor as a wonderful engine, maintaining that in lightness, economy and simplicity it has no superior in Europe. An important outstanding feature was a single design for many services as compared to at least thirty different makes in France or in England. The advantage in supplying repair parts is self-evident. Dimensions of cylinders and parts are standard throughout. To increase the power is merely a question of adding more cylinders. The speaker gave a clear idea of the conditions in service, distinguished between the different types of airplane, and at the end was flooded with a variety of questions pertinent to the subject under discussion.

Ninth Annual Dinner of the Boston Engineers

The Engineers of Boston held their ninth annual dinner at the Boston Club on the evening of Apr. 30 under the auspices of the Boston Society of Civil Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. Mayor A. J. Peters was present and made a short address. William H. Blood, Jr., of the American International Shipbuilding Corp., gave a description, illustrated by lantern slides and moving pictures, of the Hog Island shipyards. Arthur D. Flinn, secretary of Engineering Council, told of the organization of the council, its purposes and processes. Maj.-Gen. E. F. Hodges spoke briefly, and A. M. Westendorf showed films of a 22-ft. motor boat which could be maneuvered, reversed and steered both backward and forward by a simple manipulation of the rudder, without altering the direction or speed of the engine. Prof. Charles M. Spofford was chairman of the committee, and James W. Rollins toastmaster.

Interior Surface Defects as Cause of Condenser-Tube Corrosion*

By W. Reuben Webster

It is the belief of some engineers that defects on the interior surfaces of brass condenser tubes act to accelerate corrosion and that accordingly their presence even to a small degree should not be tolerated. Extended observation has failed to furnish a basis for such a belief. Many observations have developed the fact that the variety of corrosion that exhibits itself in local pitting resulting in perforation takes place independently of any interior defects that may exist. No tendency of the pitting to localize on or penetrate the tube at a surface defect has been observed.

It is a common experience to find clauses in specifications that have been adopted by the writer thereof because the requirements which they demand appear to be reasonable but which have, as a matter of fact, no basis either in theory or experience.

Certain users of brass condenser tubes have been impressed with the belief that interior surface defects operate to produce corrosion which exhibits itself in the formation of local pitting, terminating in perforation. The writer at one time held this belief and took occasion to make a careful examination of every case of corrosion of this character which came under his notice, with a view to observing whether there was any evidence in support of it. No case, however, has ever been found by him which would support any such view. It has not been found possible to show that tubes that contained such interior surface defects were any more subject to corrosion than those that were free from them.

It has further been observed that there is no tendency whatever for areas of corrosion to localize in the vicinity of such defects. Moreover, many cases have been found in which severe pitting had occurred in the vicinity of such defects, but no tendency of the corroded areas to follow along the lines of defect has been noticed.

A recent case of severe corrosion was observed which furnishes strong evidence that no such connection exists. The tubes had been in service in the condenser of a large stationary plant for a period of six months, and were removed because of perforations caused by local corrosion on their interior surfaces. Of a lot of eleven tubes, eight were found to be free from surface defects in the vicinity of the corroded areas, while three samples were found to contain such defects. These tubes were sawed longitudinally and opened out flat so as to show the interior surfaces. Three characteristic samples from the unblemished tubes were photographed for comparison with three containing surface defects.

Particular attention is called to the fact that even where a corroded area crosses a defect, no tendency whatever for corrosion to follow the defect is observable. In most of the samples the corroded area was confined to a distance not over four inches from the inlet end of the tube; the remainder of the tube being as free therefrom as when first made. In one or two cases the corroded area was similarly confined to a short distance in the length of the tube, but was some distance from its end.

The effect that temperature has upon corrosion was well shown by the fact that the corroded area in most cases stops quite abruptly on reaching that portion of the tube in contact with the tube sheet. There would be a considerable difference in temperature between the portion of the tube in contact with the tube sheet and that in contact with the steam.

It is not intended that the evidence herewith presented should be considered as arguing in favor of the presence of defects of this character. It is, however, a fact that evidence of their existence can be largely removed by treatment that detracts from the resistance of the tube to corrosion, while on the other hand they are rendered more highly visible by treatment that tends materially to increase this resistance.

As a consequence, tubes treated in a manner tending to decrease their serviceability will frequently be accepted under specifications containing restrictions of the character in question, but would be rejected when made in accordance with methods calculated to give them the maximum endurance.

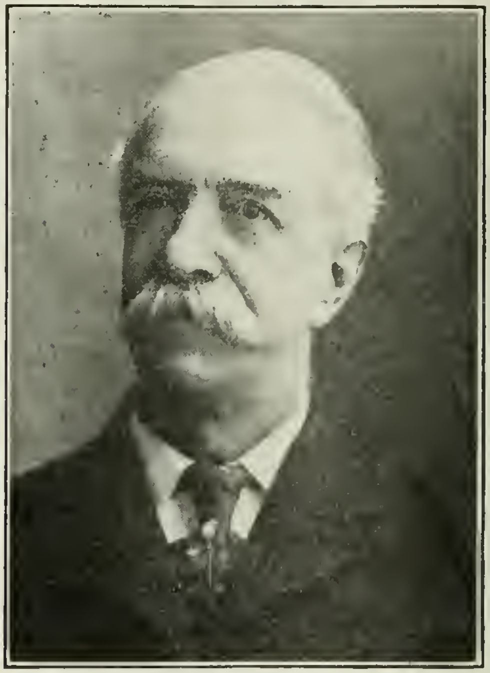
It, therefore, follows that a rigidly interpreted clause of this nature may operate to weaken rather than strengthen the specifications of which it is a part.

---

*From a paper before the American Society for Testing Materials.

Charles Jenkins

Charles Jenkins died May 1, 1918, at his summer home at Winthrop Heights, Mass. He was born in Boston in 1852, the son of Nathaniel Jenkins, the inventor of the well-known Jenkins valve. After the death of their father in 1872, the brothers, Alfred and Charles, formed a partnership under the name Jenkins Brothers, to continue the business of their father. Charles remained a member of the firm until 1896, when he sold his interest to his brother and retired to devote his time to his real-estate interests in Boston, residing at 847 Beacon Street.



CHARLES JENKINS

Submarine Engineer Officers Wanted

The Navy is in need of professional engineers for submarine duty, not over 35 years old and physically strong. The qualifications include citizenship in the United States, the degree of mechanical, electrical or mining engineer from a university of recognized technical standing and at least two and one-half years' practical engineering experience. The candidates selected will be commissioned Ensign in the U. S. Naval Reserve Force, and will be sent to the Naval Academy and to the Submarine School in New London for a special technical course.

Engineers subject to the Selective Draft Law and those now in the Army are eligible. Letters from at least three responsible personal acquaintances must accompany each application. Address the American Engineering Service of the Engineering Council, Room 903, 29 West 39th St., New York City. Early responses are requested.

A book will tell you how to open or close a throttle, but that operation is not all there is to starting and stopping an engine. You can get information from books, but never skill.—*Marine Engineering.*

Personals

C. A. Binz, formerly manager of the meter department of Yarnall-Waring Co., is now sales manager of the company.

Albert Tate Smith has returned to The Permutit Co., with which he was formerly connected, to take the position of assistant manager of sales.

Thomas C. Green, of the Garlock Packing Co., Pittsburgh branch, has recently been appointed secretary of the National Exhibitors' Association connected with the N. A. S. E. in place of J. William Peterson, of the Richardson-Phenix Co., resigned.

Laura G. Edwards, who was connected with the advertising department of the National Tube Co. in Pittsburgh and Kewanee for over 12 years, resigned to enter upon a broader opportunity in the publicity department of the A. M. Byers Co. on Apr. 1.

F. W. Fischer has resigned as chief engineer of the Standard Knitting Co., of Knoxville, Tenn., to accept a position with the Air Nitrates Corporation. After a few weeks spent in studying the processes at Niagara and elsewhere, he will assist in the installation of the U. S. Nitrate Plant No. 2 at Muscle Shoals, Ala.

Prof. F. H. Newell, head of the Department of Civil Engineering at the University of Illinois and organizer and director of the United States Reclamation Service, has been awarded the Cullom Geographical Medal by the Geographical Society of New York. Professor Newell is a prominent member of the American Society of Mechanical Engineers and of the American Association of Engineers.

Engineering Affairs

Perth Amboy No. 13, N. A. S. E., will hold its 27th annual state convention, June 1-2. Exhibits will open on May 31.

The Southeastern Section of the National Electric Light Association will hold its annual meeting at Atlanta, Ga., June 19-20.

The American Institute of Chemical Engineers will hold its summer meeting at Berlin, N. H., June 19-22, with headquarters at Mt. Madison House, Gorham.

The New Haven Section of the A. S. M. E. will hold a meeting on May 10. There will be papers and informal talks by engineers of local companies on "Munitions Manufacture."

The Power Section of the Providence Engineering Society will hold a meeting on the evening of May 8, 1918, at which L. B. McMillan, of New York, will give a talk on "Thermal Insulation."

The New Orleans (La.) Section of the A. S. M. E. will hold a joint meeting with the Louisiana Engineering Society on May 13. Dr. Winship will present a paper on "Power Plants of the Oil Tankers Being Built at New Orleans"

The American Order of Steam Engineers will hold its 32nd annual convention at the Parkway Building, Broad and Cherry Sts., Philadelphia, June 10-12. Owing to general existing conditions, there will be no exhibit held in connection with the convention this year.

The National Electric Light Association will hold its regular annual meeting this year in Atlantic City, N. J., with the Hotel Traymore as headquarters, June 13 and 14. The sessions will be devoted entirely to a consideration of vital war problems as related to the industry. In view of the fact that practically all member companies are short-handed and their officers have their time taken up not only with general problems of the industry, but also with local problems and difficulties that come upon them as patriotic citizens, it is believed that the attendance will inevitably be much smaller and more restricted than would occur in normal times and under the usual conditions, all other subjects, however important, being swallowed up for the time being in the fundamentally vital and essential one of winning the war.

The National Gas Engine Association will hold its eleventh annual meeting at the Sherman Hotel, Chicago, June 3-4. The subjects to be discussed on Monday are as follows: "The Iron and Steel Situation"; "Government Requirements on Gas Engines and the Method of Handling Those Matters at Washington"; "The Labor Situation"; "The Fuel Problem," which will be handled by a representative of the Federal Fuel Administration. On Tuesday forenoon the following paper will be read: "What Is the Future of the Farm Gas-Engine Business"; "Sizes of Manufacture from the Manufacturing and Sales Standpoint"; "The Present Condition and Future of the Gas-Engine Export Trade." On Tuesday afternoon there will be a technical session in connection with the Mid-West Section of the Society of Automotive Engineers, at which several papers of a technical nature will be presented and discussed.

The American Institute of Electrical Engineers will hold its 34tn annual convention at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 26-28, 1918. Six technical sessions are contemplated. The convention will open at 10:30 a. m. on Wednesday June 26, with President E. W. Rice, Jr.'s, address. This will be followed by the technical committee reports. The following papers will be presented Wednesday, 2:30 p. m.: "Split-Conductor Cables—Balanced Protection," by William H. Cole; "Overhead Transmission Cables," by E. B. Meyer; "The Application of Theory and Practice to the Design of Transmission Line Insulators," by G. I. Gilchrist. Thursday, 10:30 a. m.: "Lightning-Arrester Spark Gaps," by C. T. Allcutt; "The Oxide-Film Lightning Arrester," by C. P. Steinmetz: "Design of Transpositions for Parallel Telephone and Power Circuits," by H. S. Osborne. Thursday, 2:30 p. m.: Members and section delegates conference. Thursday, 8.30 p. m.: "Fixation of Nitrogen," by E. Kilburn Scott; "America's Power Supply," by C. P. Steinmetz. Friday, 10:30 a. m.: "Precharged Condensers," by V. Karapetoff; "Method of Symmetrical Coördinates Applied for the Solution of Polyphase Networks," by C. L. Fortescue: "Flux Distribution in Alternators Under Sustained Short-Circuit Conditions and Different Loads," by N. S. Diamant. Friday. 2:30 p. m.: "Protection from Flashing in D. C. Apparatus," by J. J. Linehaugh and J. L. Burnham; "The Automatic Hydro-Electric Plant," by J. M. Drabelle and L. B. Barnett.

Miscellaneous News

The New Transmission Line from Windsor, Vt., to Claremont, N. H., has been completed and is now in operation. Some economics in operation and better service should be effected through this new line.

Excavation Work for the new 10,000-kw. turbine to be installed at the Dock Street plant, Easton, Penn., has been started. Provided no unusual difficulties are met with, this turbine should be in operation by Aug. 1, next.

A Boiler Exploded at a grist mill on White Oak Creek, in Estill Co., Ky., on Apr. 5, instantly killing two men and injuring half a dozen, one of whom died later from injuries and another lay at the point of death at the time this report was received. The mill was blown some distance from its foundation, and every one in it was more or less seriously injured.

The Eighth Edison Medal has been awarded by the Edison Medal Committee of the American Institute of Electrical Engineers to Col. John Joseph Carty for his work in the science and art of telephone engineering. The medal will be presented to Colonel Carty at the annual meeting of the Institute to be held in the Auditorium of the Engineering Societies Building, Friday, May 17, 1918, at 8:30 p. m. President E. W. Rice, Jr., will preside and the program will be: Address by A. E. Kennelly, outlining the origin and purpose of the Edison Medal; address by Michael I. Pupin, giving history of Colonel Carty's work in regard to telephone engineering; presentation of medal by President Rice; acceptance of the medal by Colonel Carty.

The Output of Bituminous Coal increased 366,000 net tons, or 3.4 per cent. during the week ended Apr. 27, compared with the week previous. We are not, however, getting out the large production that we should, in order to provide for the excessive demand of the coming winter. A part of the falling off is due to lack of cars, many of which have been diverted to meet the demand of the army on account of the drive on the West front. Some of the mines which could get cars are actually idle for lack of orders. It is not known to what extent cars are being added to the railroad equipment. The way that the consumer can help most is to get in orders for all that he is going to need next winter as early as possible, and to take and store all that he can, but not, of course, in excess of his probable requirements.

NEW CONSTRUCTION

Proposed Work

Mass., Newburyport—The Newburyport Gas and Electric Co., 49 Pleasant St., plans to build an addition to its new electric plant on the former Fiberloid wharf. C. Spaulding, Supt.

Mass., Westfield—City plans to appropriate $42,000 to purchase equipment for its light department to enable it to utilize power from the Turners Falls plant.

N. Y., Geddes—The Syracuse Lighting Co., plan to build a brick electric plant. B. H. Shepard, 514 City Bank Bldg., Syracuse, Pres.

N. Y., Groton—The Groton Electric Co., is having plans prepared for the erection of an electric power plant. F. J. McGee, 622 East 113th St., New York City, Pres. Noted Oct. 7.

N. Y., Marshall—The Waterville Gas and Electric Co. plan to build an electric plant B. H. Shepard, 514 City Bank Bldg., Syracuse, Pres.

N. Y., Mohawk—State is having plans prepared by F. M. Williams, Engr., Capitol, Albany, for the erection of a hydraulic power plant on the State Barge Canal here.

N. Y., New York—The Bellevue and Allied Hospitals plan to build a new power plant at the foot of East 26th St.

N. J., Camden—Kind & Lantesmann, 5th St., has had plans prepared for the erection of a new boiler plant.

N. J., Jersey City—Swift & Co., 154 9th St., plan to build a 2-story addition to its engine and power plant on Henderson St. Estimated cost, $23,700.

N. J., Newark—A. Fink and Son, 810 Frelinghousen Ave., has had plans prepared for the erection of an addition to its engine house in connection with its factory.

N. J., Pompton Lakes—City has voted $46,900 bonds for the erection of an electric power plant on Corning Lake.

N. Y., Brooklyn—The State Hospital Commission, Albany, will receive bids until May 22, for installing underground connections and building an addition to its boiler house. E. S. Elwood, Secy.

Penn., Germantown—City plans to build an electric lighting plant on Duval and McCallum St.

Penn., McKeesport—The Atlantic Refining Co., 6th Ave., Pittsburgh, plan to build a service station on Walnut St. and 8th Ave. Estimated cost, $15,000.

Penn., Steelton—The Bethlehem Steel Co. plan to install four 250 hp boilers each, in its new addition now under construction.

Va., Richmond—Hackley Morrison, Moore Bldg., 16 North 9th St., is in the market for a 75 kw., 125 volt, direct current generator directly connected to a generator.

Ga., Commerce—City voted to issue $15,000 for the erection of electric lighting plant. C. A. Goodin, Clerk and Treas. Noted Apr. 16.

Ga., Jefferson—City issued $15,000 bonds for an electric lighting plant and water works system. Noted Feb. 19.

Fla., Oldsmar—The Oldsmar Electric and Ice Co., recently incorporated, plan to install an electric lighting plant and ice factory. J. Bornstein, Pres.

S. C., Branchville—P. Ott is in the market for equipment for an electric lighting plant.

Miss., Purvis—City retained N. A. Kramer, Engr., Magnolia, to prepare plans for the installation of an electric lighting system here.

La., Monroe—The Standard Gin Co., recently organized with $60,000 capital stock, is in the market for power plant, and cotton gin equipment. J. P. Parker, S. Schienker and J. T. Austin, incorporators.

La., Powhattan—The Yarborough Co plans to purchase Scotch boilers and other power plant equipment.

Ohio, Columbus—The Columbus Anvil and Gorging Co. plan to build a new power plant in connection with its factory on West Frankfort St. T. N. Long, Mgr.

Ohio, Lowellville—The Sharon Steel Hoop Co. is in the market for a 15-ton electric crane for its finishing mills here.

Ohio, Mansfield—The City School District will receive bids until May 15, for the construction of a heating and ventilating system in the Brinkerhoof School on Marion Ave. J. H. Bristor, Clerk.

Ohio, St. Paris—City voted $5500 bonds for improvements to its electric lighting plant.

Ind., Indianapolis—The Ross Power Equipment Co., Merchants Bank Bldg., is in the market for a 250 kv.-a., 240/440 volt, 60 cycle, 3 phase engine type generating unit for 125-150 lb. steam, 3-5 lb. back pressure, one 400 kv.-a. generating unit, same as above, one 150 kw., 250 volt compound generating unit directly connected and one 250 and one 500 kw., either simple or tandem, compound engines.

Ill., Pecatonica—City plans to install an electrically operated pump at its pumping station after July 1.

Wis., Eau Claire—The Standard Oil Co. of Indiana, plans to build a complete service and distributing group here. Estimated cost, $30,000. W. W. Holcomb, La Crosse, Dist. Mgr. R. M. Adams, 72 West Adams St., Chicago, Archt.

Wis., Menasha—City is considering the installation of an additional engine in its electric lighting and water works plant.

Wis., Winneconne—The Winnebago Electric Co., recently incorporated, plans to establish an electric lighting plant here. R. W. Button, interested.

Iowa, Eldora—Hardin Co. receives bids about June 11 for brick boiler house, smoke stack, etc. About $15,000. C. Boylan, Co. Aud

Iowa, Red Oak—The Red Oak Electric Co. has applied to the Board of County Supervisors for a franchise to build and operate an electric transmission line on certain roads in Pleasant Township.

Minn., Virginia—City plans to build heating plant.

Kan., Brookville—City voted to issue bonds for the erection of an electric distribution system.

Neb., Lynch—City voted $7800 bonds for the installation of an electric lighting plant.

Ark., Little Rock—The Board of Education will soon award the contract for the installation of a heating and lighting system in the grade and junior high school. L. Thompson and T. Harding, 504 Southern Trust Bldg., Archs.

Tex., Beaumont—The Kansas City Southern R. R. Co., Kansas City, Mo., plans to install electrical equipment to operate the drawbridge over the Neches River here. J. M. Wier, Kansas City, Mo., Ch. Engr.

Okla., Blocker—The Tri State Coal and Coke Co., recently incorporated with $100,000 capital stock, is in the market for mining and power plant equipment.

Okla., Gotebo—City plans to rebuild its electric lighting plant recently destroyed by fire.

Okla., Kiowa—The Kiowa Ice, Light and Water Co., recently incorporated with $50,000 capital stock, plans to install an electric plant and an ice factory. T. L. Sammons and M. T Crane, interested.

Okla., Savannah—The Savannah Lighting and Milling Co., incorporated with $2000, plans to install a lighting plant.

Wash., Ephrata—The Ruff Lighting Co. has petitioned the Commissioners of Grant Co. for authority to build an electric transmission line along the highway in Grant County. S. R. Nelson and C. Reeder, incorporators.

Calif., Los Angeles—F. W. Slinkard, 1437 Wright St., is in the market for 25-30 motors, 440 3 phase vertical centrifugal pump with frame, No. 7.

N. S., Berwick—City plans to build an electric lighting and power plant. Estimated cost, $50,000. H. A. Cornwall, Clerk.

N. S., Halifax—The Nova Scotia Tramways and Power Co. plans to purchase new equipment including electric streets cars, electrical equipment and generating machinery. G. A. Fowler, Lower Water St., Engr.

Que., Makamik—Boisclair Bros. is in the market for sawmill and steam power equipment.

Que., Shawinigan Falls—The Laurentide Power Co. plans to install 3 additional units in its plant. J. E. Aldred, 24 Exchange Pl., New York City, Pres.

Ont., Dunwich Twp.—The Dominion Natural Gas Co., Ltd., Bank of Hamilton Bldg., plans to lay mains and establish a distributing system througnout the township.

Ont., Wallaceburg—The Dominion Glass Co. plans to install a gas producer plant. Estimated cost, $200,000.

Alta., Calgary—City is in the market for a motor generator set.

B. C., North Vancouver—City is considering plans for the erection of a hydro electric plant on the property of the Nairn Falls Power Co.

B. C., Revelstoke—The Lanark Mines Co. plans to build a power plant and dam in connection with its mine and mill here. Estimated cost between $25,000 and $30,000.

CONTRACTS AWARDED

N. H., Plymouth—The Plymouth Electric Light Co. is building a 2-mile electric transmission line from here to Livermore Falls. J. A. Walls, Lexington St. Bldg., Baltimore, Md., Engr.

Mass., Cambridge—The Technology has awarded the contract for the erection of a 1-story, 43 x 190 ft. engine building, to Stone and Webster Engineering Corporation, 147 Milk St., Boston. Estimated cost, $12,000.

N. Y., Binghamton—The Binghamton Light, Heat and Power Co. is building an addition to its electric power plant.

Penn., Philadelphia—The E. F. Benson Co., 926 North Delaware Ave., has awarded the contract for the erection of an engine plant, to W. Steele & Sons Co., 31 South 15th St.

Penn., Pittsburgh—The Heppenstall Forge and Knife Co., 47th and Hatfield St., has awarded the contract for the erection of a new boiler plant to C. Huntsman, Pittsburgh. Estimated cost, $23,000.

Wash., D. C.—The Bureau of Yards and Docks, Navy Dept., Wash., has awarded the contract for the erection of a frequency changer house and a substation, to the Dawson Constr. Co., May Bldg., Pittsburgh, Penn. Estimated cost, $52,520.

Calif., San Pedro—The Seacoast Canning Co., Los Angeles, has awarded the contract for the erection of a cannery and a brick boiler house here, to F. W. Colegrove, 573 7th St. Estimated cost, $23,000.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular May 2, 1918	Individual May 2, 1918
Buckwheat	$4.60	$7.10—7.35
Rice	4.10	6.65—6.90
Boiler	3.90	....
Barley	3.60	6.15—6.40

BITUMINOUS

Bituminous not on market.

Pocohontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.00 a year ago.

*All-rail to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* are as follows:

ANTHRACITE

	Circular May 2, 1918	Individual May 2, 1918
Pea	$4.90	$5.65
Buckwheat	4.45@5.15	4.80@5.50
Barley	3.40@3.65	3.80@4.50
Rice	3.90@4.10	3.00@4.00
Boiler	3.65@3.90	....

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Gross	Mine Price Net	Gross
Central Pennsylvania..	$5.06	$3.05	$3.41
Maryland—			
Mine-run	4.84	2.85	3.19
Prepared	5.06	5.05	3.41
Screenings	4.50	2.55	2.85

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty, Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The ratte to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	May 2, 1918	One Yr. Ago	May 2, 1918	One Year Ago
Pea	$3.45	$2.80	$4.35	$3.70
Barley	2.15	1.50	2.40	1.75
Buckwheat ..	3.15	2.50	3.75	3.40
Rice	2.65	2.00	3.65	3.00
Boiler	2.45	1.80	3.55	2.90

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes...	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Ill., Pocohontas, Pennsylvania and W. Va.	Hocking, East Kentucky and West Va. Splint
Prepared sizes...	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices per net ton f.o.b. mines are as follows:

	Williamson and Franklin Counties May 2, 1918	Mt. Olive & Staunton May 2, 1918	Standard May 2, 1918
6-in. lump	$2.65-3.00	$2.65-2.80	$2.65-2.80
2-in. lump	2.65-3.00	2.65-2.80	2.25-2.50
Steam egg....	2.65-2.80	2.35-2.50	2.25-2.40
Mine-run	2.45-2.60	2.45-2.60	2.45-2.60
No. 1 nut.....	2.65-3.00	2.65-2.80	2.65-2.80
2-in. screen....	2.15-2.40	2.15-2.40	2.15-2.40
No. 5 washed..	2.15-2.30	2.15-2.30	2.15-2.30

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump & Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba.	2.40	2.65	2.15

Government figures.

Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

Prices—Materials and Supplies

These are prices to the power plant by jobbers in the larger buying centers east of the Mississippi. Elsewhere the prices will be modified by increased freight charges and by local conditions.

ELECTRICAL SUPPLIES

KNIFE SWITCHES—Following are net prices each in cities named for knife switches mounted on slate base, front connected, punched clip type, 250 volts:

	30 Amp.	60 Amp.	100 Amp.	200 Amp.
D. P. S. T. fuseless	$0.52	$0.93	$1.90	$3.42

PIPE COVERING		BLOCKS AND SHEETS	
Pipe Size	Standard List Per Lin.Ft.	Thickness	Price per Sq.Ft.
1-in.	$0.27	½-in.	$0.27
2-in.	.36	1 -in.	.30
6-in.	.80	1½-in.	.45
4-in.	60	2 -in.	.60
3-in.	.45	2½-in.	75
8-in.	1.10	3 -in.	.90
10-in.	1.30	3½-in.	1.05

85% magnesia high pressure		5% off
For low-pressure heating and return lines	4-ply	58% off
	3-ply	60% off
	2-ply	62% off

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots:

	Cincinnati	Chicago	St. Louis	Birmingham	Denver
Cup	7	5¼	6.9	7½	10½
Fiber or sponge	8	6	7.4	7½	15
Transmission	7	6	7.4	7½	13
Axle	4½	4	3.6	3	5
Gear	4½	4½	7.0	7½	6
Car journal	22 (gal.)	3½	4.5	3	6

COTTON WASTE—The following prices are in cents per pound:

	Chicago	New York		Cleveland
		Current	One Year Ago	
Colored mixed	12.00 to 12.50	8.50 to 12.00	10.00 to 12.00	12.50
White	10.00 to 11.00	11.00 to 13.00	13.00 to 15.00	16.00

WIPING CLOTHS—In Cleveland the jobbers' price per 1000 is as follows:

13¼ x 13½	$45.00	13¼ x 20½	$52.00

In Chicago they sell at $30@33 per 1000.

LINSEED OIL—These prices are per gallon:

	New York		Cleveland		Chicago	
	Current	One Year Ago	Current	One Year Ago	Current	One Year Ago
Raw per barrel	$1.55*	$1.13	$1.65	$1.13	$1.65	$1.05
5-gal. cans	1.65*	2.23	1.80	1.23	1.75	1.15

* Nominal.

WHITE AND RED LEAD in 500-lb. lots sell as follows in cents per pound:

	Red				White	
	Current		1 Year Ago		Current	1 Yr. Ago
	Dry	In Oil	Dry	In Oil	Dry and In Oil	Dry and In Oil
25- and 50-lb. kegs	11.50	11.00	10.50	11.00	10.50	10.50
12½-lb. keg	11.75	11.25	10.75	11.25	10.75	10.75
100-lb. keg	11.25	11.50	11.00	11.50	11.00	11.00
1- to 5-lb. cans	13.25	13.00	12.50	12.50	13.00	12.50

Note—Price change imminent

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel 7/16 and smaller	30%	35%	40%*
Tinned	30%	35%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York ..... $6.09½ Cleveland ..... $5.85 Chicago $5.50

Coneheads, same sizes:

New York ..... $6.19½ Cleveland ..... $5.95 Chicago $5.60

FIRE BRICK—Quotations on the different kinds in the cities named are as follows, f.o.b. works:

	New York	Chicago
Silica brick, per 1000	$50.00 to 55.00	$50.00
Fire clay brick, per 1000, No. 1	45.00 to 55.00	....
Magnesite brick, per net ton	135.00 to 145.00	....
Chrome brick, per net ton	....	....
Deadburned magnesite brick, per net ton	85.00 to 90.00	....
Special furnace chrome brick, per net ton	......	60.00 to 80.00

Standard size fire brick, 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade, $55 to $65; St. Louis grade, $40 to $55.
Birmingham—Fire clay, $35.
Chicago—Second quality, $25 per ton.
Denver—Silica, $35 per 1000.

FUEL OIL—Price variable, depending upon stock. New York quotations not available owing to this fact. In Chicago and St. Louis the following prices are quoted:

	Chicago	St. Louis
Domestic light, 22-26 Baumé	5c.	None
Mexican heavy, 12-14 Baumé	7c.	7 1/10c.

Note—There is practically no fuel oil in Chicago at present time.

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Current	One Year Ago
New York	$15.00	$9.50
Cleveland	15.00	7.00
Chicago	15.00	8.25

In coils an advance of 50c. usually is charged
Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St. Louis	Denver
6 in. by 30 ft	$5.59	$4.94	$4.94	$4.32
7 in. by 30 ft	7.40	6.60	6.60	5.80
7 in. by 35 ft	10.70	9.60	9.60	8.55
8 in. by 35 ft	12.20	10.90	10.90	9.65
7 in. by 40 ft	12.35	11.00	11.00	9.75
8 in. by 40 ft	13.75	12.15	12.15	10.65
8 in. by 45 ft	18.20	16.20	16.20	14.30
8 in. by 50 ft	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads.

For plain pine poles, delivered New York, the price is as follows:

10-in. butts, 5-in. tops, length 20-30 ft	$ 9.00
12-in. butts, 6-in. tops, length 30-40 ft	11.50
12-in. butts, 6-in. tops, length 41-50 ft	12.50
14-in. butts, 6-in. tops, length 51-60 ft	21.00
14-in. butts, 6-in. tops, length 61-71 ft	23.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh, basing card in effect July 2, 1917, for iron, and May 1 for steel:

BUTT WELD

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized
¾ to 3	49%	35½%	¾ to 1½	33%	17%

7 to 8	38%	24½%	2½ to 4	29%	17%
9 to 12	33%	19½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts bold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	38%	42%	34.27%
3½ to 6 in. lap welded	18%	38%	21.27%
7 to 12 in. lap welded	10%	35%	21.27%

	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	22%	22%	19.27%
3½ to 6 in. lap welded	List	18%	13.27%
7 to 12 in. lap welded	List+20%	20%	6.27%

Malleable fittings, Class B and C, from New York stock sell at 5 and 5% from list prices Cast iron, standard sizes, 34 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13, as agreed upon by manufacturers and the Government:

Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+ 5
2¼ in.	17½	2½ to 2¾ in.	+ 7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

	Per Net Ton		Per Net Ton
1 in.	$340	1¾ in.	$220
1¼ in.	280	2 to 2½ in.	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

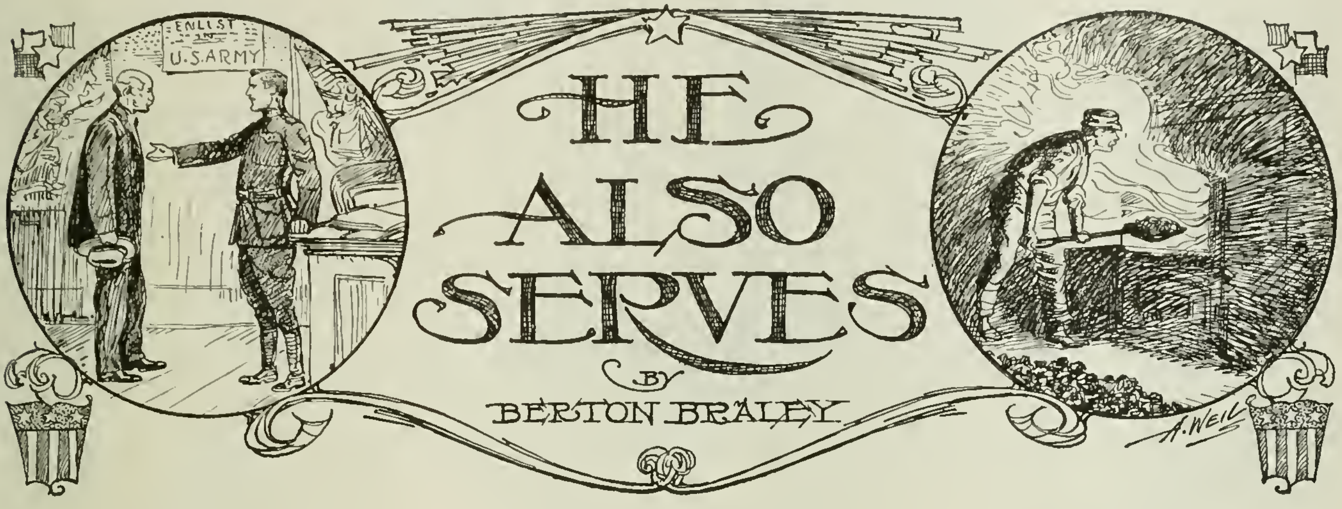
These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

POWER

Vol. 47 NEW YORK, MAY 14, 1918 No. 20

HE ALSO SERVES

BY BERTON BRALEY



Seemed sort of hard, at first, I couldn't go
To fight beside the boys acrost the sea.
I tried, all right, but sergeant he says, "No.
You're over age for soldierin'," says he.
"Look here," says I, "I may be over age,
But see this chest, these muscles, an' these hands—
I ain't too old to earn a fireman's wage,
Why won't I do to fight in furrin' lands?

"The kids is growed," I says, "an' Jim an' John
Is over there; I got a bit laid by,
The wife she wouldn't starve while I was gone,
I'd like to fight with my two boys, an' I
Could do my bit, I know." The sergeant smiles,
"I know you could," he says, "but man alive,
I'd get called down in fifteen diff'runt styles
If I took you—you're over forty-five."

So I goes back to work—not feelin' gay,
An' thinkin', "Hell, it's fierce to be so old!"
But then it sort of comes to me next day
That after all, the guys that are enrolled
As soldiers ain't the only ones that serve,
An' us at home can do our bit, all right.
I guess a man can use his strength an' nerve
To *work* for Uncle Sam, as well as fight.

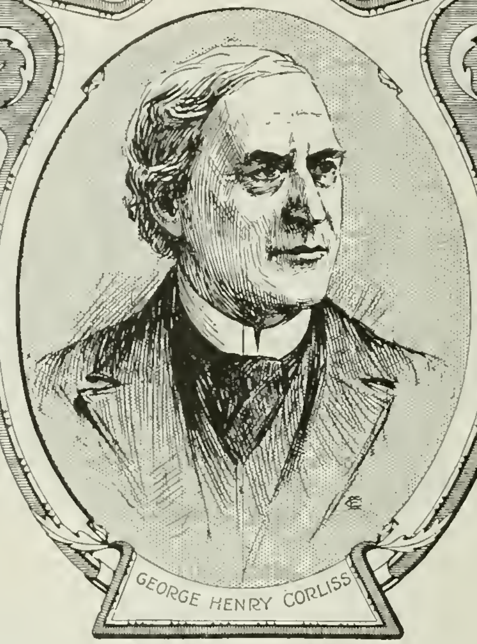
So now I watch my fires an' save my coal
(That's helpin', when you think what fuel means),
An' do my job with all my heart an' soul
Makin' the steam that's drivin' our machines;
For it's machines that's gonta win this war
Cuttin' an' shapin' guns an' other things
That's used to aid our boys who're fightin' for
The old U. S. against them Prussian Kings.

Here in the basement where the boilers hum
I have enlisted till the war is won,
There ain't no music of a fife an' drum
To cheer my spirits while my work is done,
But with my shovel an' my slice-bar, too,
I toil an' sweat an' never make a yelp,
I'm in the service till the game is through,
Too old to fight, but not too old to help!

The "One Hundredth Anniversary" of George Henry Corliss

By H. F. Mueller

CHIEF ENGINEER of WASHBURN-CROSBY MILLS, MINNEAPOLIS, MINN.



GEORGE HENRY CORLISS

GEORGE HENRY CORLISS was born in Easton, N. Y., June 2, 1817. He was the son of a doctor, and although he did not follow the footsteps of his father, trying to make people healthy, he became nevertheless a doctor indeed, a doctor of the engineering profession. He was a man of strong and determined character, who could not only make decisions but carry them out in spite of difficulties and resistance. He was a religious man and always polite and kind and anticipatory in his manners. He lived in a plain cottage near his factory and devoted his spare time to his family. There alone he sought and found recreation and enjoyment. He was very fond of the lawn around his house and took great care of it. "Such a lawn as mine," he would declare boastfully, "cannot be found in the whole United States." Corliss received many honors and appreciations. At every exposition he received the highest awards even if he had no exhibit at all; for instance, at the World's Fair in Vienna, he received the Gold Medal for the reason that most of the engines exhibited were built after the Corliss patents. In 1870 The American Academy of Arts and Sciences awarded Corliss the Rumford Medal.

Since James Watt's time no name has been so often or so intimately connected with the steam engine as the name of Corliss. The work of this great American marked a new step in the development of the steam engine. His improvements revolutionized the steam-engine business and gave his name an everlasting fame.

He died in February, 1888, after a short illness, thirty years ago, but his engine has held its place at the head for nearly three-quarters of a century. Many and various and some fearful and wonderful attempts have been made at various times to produce an engine to supersede it, but so far with little success, and through all these years, the Corliss engine has maintained its proud position as the standard mill and factory engine. We first find young Corliss working as a clerk in a store. Next it is reported that he erected a general merchandise outfit of his own in a small country town, but, at about 22 years of age, realizing that the monotony of the village threatened to dull his senses, he shut down that plant, dismantled it, went to a larger city and found employment in a shoe factory. The noise of the factory, the humming sound of the moving machinery was classic music in the ears of young Corliss. He remained in the shoe factory about four years, and his remarkable ability for technic and construction soon became known. He made here his first invention, a sewing machine, and it was to get it built that Corliss left the shoe factory and went to Providence, R. I., the only place at that time where such work could be done. He arranged with the firm of Fairbanks & Bancroft, then doing a machine and engine business, and started at once with the perfection of his sewing machine. Fairbanks & Bancroft, however, soon discovered that Corliss was a man they could use to great advantage in their own employ, and as they did not care to manufacture sewing machines they closed the dampers on that work and persuaded Corliss to disconnect himself from the sewing machine and devote his time and attention to projects which they had on hand. Corliss changed over and started in a new direction. He made good, so splendidly good that inside of a year Fairbanks & Bancroft riveted young Corliss solidly to their shops by making him one of their partners. It was at this time that Corliss conceived the improvements which revolutionized the steam-engine business and made his name a household word to every engineer in the country. He made a radical departure from the customary engine design of those days by constructing a cylinder with two valve chests, one for the steam inlet and one for the exhaust outlet. He used four valves in his cylinder, one at each corner. He designed a wristplate oscillated by an eccentric, to which the four valves were connected. He designed a valve-releasing gear with dashpots to close the steam valves quickly. He attached the governor to the valve mechanism and designed an entirely new engine frame.

The first engine of Corliss design, started in February, 1848 (Corliss was then 31 years old), was a 260-hp. walking-beam engine; the cylinder, shown in Fig. 1, measured 22 in. diameter by 72-in. stroke. The inlet valves are at the left and the exhaust valves at the right. The inlet valves on the first few Corliss engines were flat and were opened and closed by small shafts with racks and pinions operated from the central wristplate. The motion rod effecting the opening had a hook on one end, held by a spring against the valve shaft, which connected to the lever and so opened the valve. After the motion rod had traveled a certain distance, it struck a wedge-shaped arrangement which disengaged the hook, and the valve was closed by a weight attached to the valve-shaft or hook lever. The cutoff was not under the influence of the governor, but set by hand. The first engine having the cutoff controlled by the governor and having cylindrical oscillating valves, Fig. 2, was built in 1850.

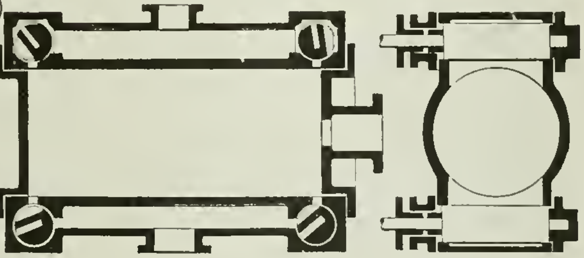

FIG. 8

FIGS. 1 TO 8. EARLY TYPES OF CORLISS VALVE GEARS

Fig. 1—The first Corliss cylinder and valve gear, 1848. Fig. 2—Valve gear of 1850. Fig. 3—Valve gear of 1851, dashpot taking shape. Fig. 4—The inclined gear of 1852. Fig. 5—"Crab-claw" gear of 1858. Fig. 6—Known as the spring-lever gear, put out in 1859. Fig. 7—Corliss' latest design, 1875. Fig. 8—Familiar Corliss cylinder and valve shown in section.

In Fig. 3 the springs holding the inlet motion rods in their respective places are fastened directly to the rods. The valves are closed by weights in smooth cylinders, but cushioned by air entrapped at the bottom of the little cylinders.

For a long time the gear shown in Fig. 4 was considered the best Corliss valve gear, and many engines were built of that design. Fig. 5 is the so-called crab-claw gear. Corliss very seldom used this gear, but some other engine builders did, especially William Harris, of Providence, R. I. It was frequently called the Harris-Corliss gear. Weights were used to close the valves on this gear.

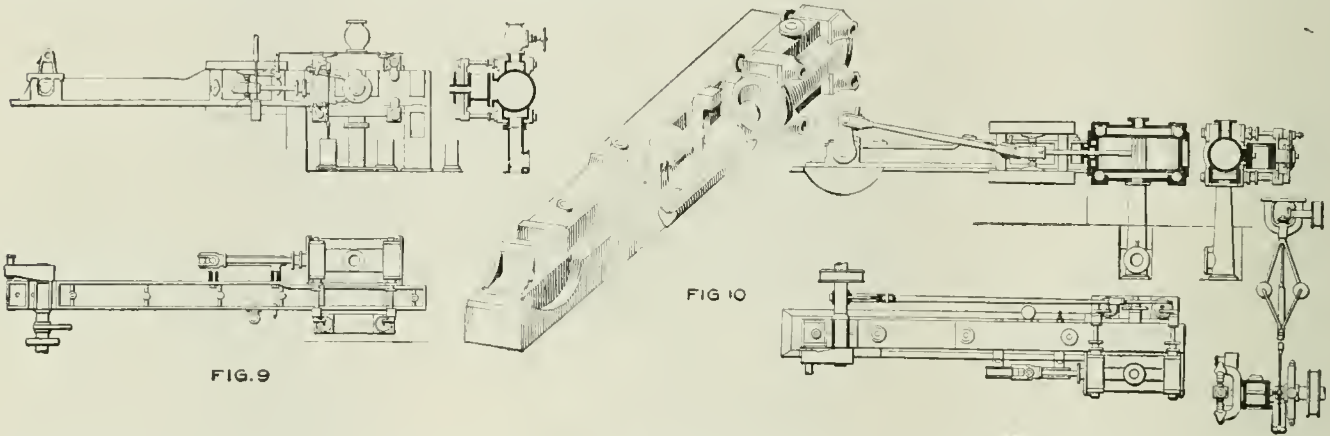
Fig. 6 is the so-called spring-lever gear, intended to do away with weights. This gear did not prove satisfactory. The springs broke frequently and were sometimes replaced by weights. A few engines were built with coil springs to close the valves, but the springs all gave trouble and Corliss fell back to the old crab-claw gear. Fig. 7 shows Corliss' latest design. Here the valves are closed neither by weights nor by springs, but by the pressure of the atmosphere on a dashpot that has a differential piston. The lower, or smaller, end, packed with a cup leather, acts as a vacuum pump; the upper or larger piston serves as an air cushion. A small check is located at the lower end of the vacuum cylinder for the escape of air leakage. To prevent the cast-iron piston striking hard metal against metal in case the vacuum is too strong and not enough air is admitted for cushioning, a leather washer is placed underneath the dash piston. This was the first valve gear designed permitting adjustment of the valves while the engine is in operation. The motion rods are threaded right and left. Fig. 8 is a sectional view of the Corliss cylinder showing the position of the valves.

Engineers laughed at the new machine and ridiculed Corliss and his inventions. They had a couplet in circulation running this way:

Levers, links and motions various,
Endless jimcracks all precarious.

But by-and-by the Corliss inventions were appreciated and Corliss was praised to the skies.

Within the year 1848 or early in 1849 Corliss had completed and had in operation two more engines like the first. Those three engines were so successful that tracts of land were purchased and extensive shops erected for the manufacture of engines. The engines installed gave excellent satisfaction, and the prospects for more and greater business were splendid, everything worked so nicely; then something serious happened which almost shut down the whole plant. Corliss took out a patent in 1849, after he had built three engines, but with this first patent troubles of large dimensions arose. Seven years prior to this a man by the name of Sickles had taken out patents on steam-engine improvements and when he heard of the Corliss patent and the wonderful success of his engine, he started to investigate and seemed to discover that the Corliss patent was very much like that of his own. Legal proceedings were the consequence, and before young Corliss realized the situation he was confronted with a high-pressure lawsuit.



FIGS. 9 TO 11. SOME EARLY TYPES OF CORLISS ENGINE FRAMES, SHOWING THE GRADUAL EVOLUTION FROM BEDPLATE TOWARD THE GIRDER FRAME

Sickles, in his legal proceedings, not only tried to prevent Corliss from manufacturing these engines, but also directed his threats against those using the engines, so Corliss had to defend himself and his customers at the same time. He had both hands full. Lawyers of the highest ability were employed on both sides, and the litigation was carried on with much bitterness. The case was tried before various juries and judges, and the fight extended over a term of 15 years. Finally, the Corliss patents were fully sustained in all points, and thenceforth, until their expiration in 1870, Corliss had the field to himself. The legal fight cost Corliss $100,000.

Many feel a certain sympathy for Sickles, who came so near achieving a great success yet missed it. The inventions of Sickles and Corliss were as different as the two men. Sickles invented an improved method of lifting, tripping and cushioning poppet valves. It seems that he had no other valve in mind; in fact, his claims are so drawn as to exclude all others. In the Corliss invention the valve does not leave its seat, it slides back and forth. As a poppet valve is dropped to its seat, it is necessary to bring the valve to rest in an extremely short distance in order to prevent slamming and destruction. Sickles used for that purpose a water dashpot. With the Corliss valve it matters little when the motion of the valve is arrested; it can pass over the ports and close them at full speed, and whether it stops a little sooner or a little later is of no consequence. Corliss brought his valves to rest by means of weights and cushioned the weight simply by an air cushion. Theoretically, the Sickles invention was all right, but the Corliss invention was the most practical one. A prominent engine designer, a man of the theory, connected with the Allis-Chalmers Co., once relieved his mind as follows: "Damn practice, it always interferes with theory." The theory that Corliss possessed never interfered with practice. Corliss' head was not filled with theory, he was a practical fellow, without college or technical training. He did not know anything about algebra, but he knew how to build useful engines right and left and put them on the market. Frederick E. Sickles was a marine engineer who fought for his theory, but a theory that interfered with practice. As stated before, Corliss got his first patent in 1849 for a term of 14 years. In 1851 and again 1859 the patent was renewed and at that time divided into six patents, each one covering a certain part of the Corliss engine. One patent was for the wristplate, one for the liberation of the valves, one for the air cushion, one for the positive closing of the valves, one for the claws and one for the combination of the governor with the cutoff.

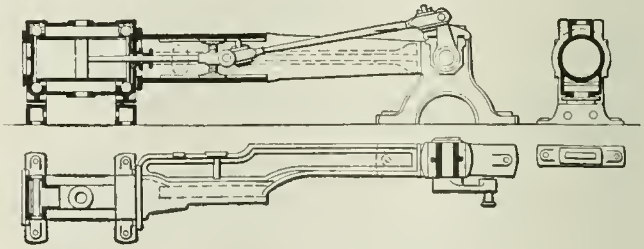


FIG. 12. THE CORLISS GIRDER-FRAME ENGINE

There was no patent on the four-valve cylinder, and the credit of originating it has been claimed by others. William Wright, at one time foreman of the Corliss shops, was one who claimed it.

ENGINE FRAMES DESIGNED BY CORLISS

Corliss not only developed the valve gear to a high degree of perfection, but all other parts of his engine also. Under the hands of this genius the whole engine soon had a different appearance in every detail. The old-style engine bed, which looked like a coffin with two low sides and a crosspiece at each end, he discarded altogether. Figs. 9, 10, 11 and 12 show the gradual development of the final standard, the familiar girder frame. First came the box-type frame, which had the shape of the letter U. The front end served as a bearing for the crankshaft, and the rear end carried the cylinder on one side and the valve gear on the other. The guides were bolted to the side of the frame. The open top of the frame was closed with a polished mahogany cover. It is said that engineers found it convenient to lay tools and things inside of the U frame, and when more than full they had some bother to make the lid fit nicely. Corliss later changed the design, turned it upside down, and the worry of the engineer in fitting the lid properly was done away with. Then came the girder, a frame extending between the main bearing and the cylinder, and carrying also the crosshead guide; the whole engine standing on the foundation instead of lying down, showing good proportions and graceful lines. Fig. 13 shows a 32 x 84-in. engine installed in 1853, in a cotton mill, to replace a Sickles poppet-valve engine that had been in operation only 2½ years, and guaranteed to effect a saving of 50 per cent. at the coal pile. Fig. 14 shows indicator diagrams from the competing engines and why Corliss effected the big saving. If Sickles had studied the poppet engines abroad and improved on his design, he could have made the road for Corliss far more difficult. Fig. 15 shows a highly developed horizontal engine.

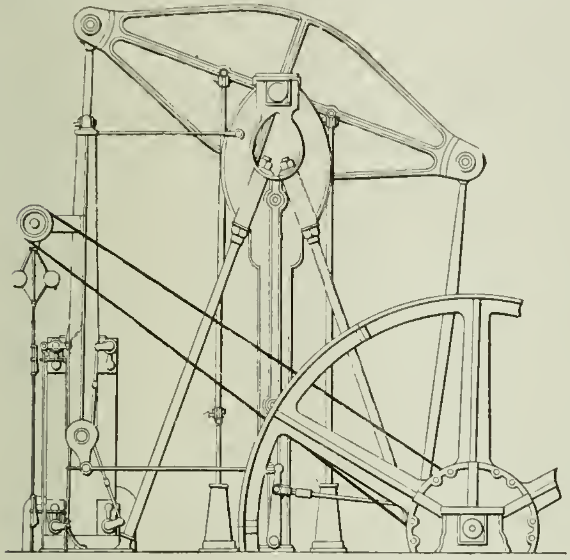

FIG. 13

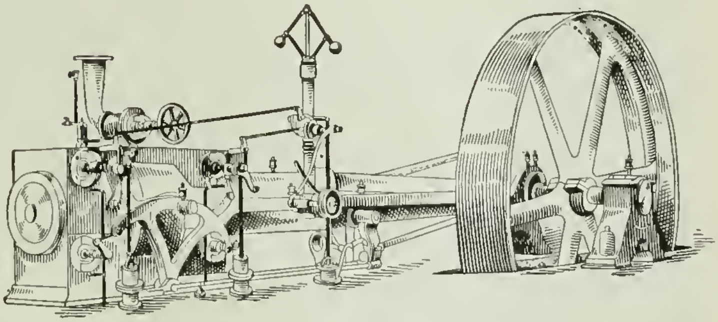

FIG. 15

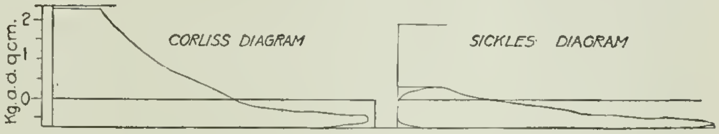

FIG. 14

FIGS 13 TO 15. EARLY AND LATER DESIGNS CONTRASTED

Fig. 13—One Corliss engine that supplanted a Sickles. Fig. 14—Shows an indicator diagram from each. Fig. 15—A typical Corliss of late design

Corliss met with considerable difficulty in finding customers for his first engines; people were prejudiced against the new machine. The valve gear was considered too complicated, and fear was expressed that it would not stand up under the working strain. Nobody believed in the advantages claimed by Corliss. To overcome this terrible resistance and secure orders for his shop, Corliss introduced his engines by giving them away and receiving as payment therefor only the savings effected over and above the old-time machines. This plan of introducing his engine proved to be all right. One of the first, a 180-hp. unit, was installed in a flour mill and the mill people agreed to give Corliss the savings over the old engines for a period of five years. Corliss realized from this outfit the sum of $19,734.22. A few more such contracts put him in shape to pay for his $100,000 lawsuits.

After the first success in economy, Corliss made the most daring guarantees for his engines the world had ever heard of. In 1852 he got a contract for an engine to drive a rail mill that he guaranteed would develop one-third more power than the old engine and at the same time reduce the daily coal bill from five tons to two tons, and in case of failure he would pay a penalty of not less than $1 for each pound of coal used in excess of his guarantee. A still bolder guarantee was made in another case. He furnished a 200-hp. engine for a certain concern for the modest price of $7100 (almost seven times as much as what an engine of that size could have been purchased for a few years ago) to replace an old one of the same size which was using over nine tons of coal per day. Corliss guaranteed that his engine would not use more than four tons, and he would pay $5000 for every ton of coal used in excess of his guarantee. Those daring guarantees soon established such a reputation for the engine that almost any price that Corliss asked would be paid. These fabulous guarantees would look suspicious to engineers of today, but notice that Corliss never guaranteed that his engine would save a certain amount in steam consumption per indicated horsepower-hour. He guaranteed the saving at the coal pile only. He was wise in doing so, for if based on the steam consumption his guarantee would never have been so big and blustering. Corliss was not only a remarkably great engineer, but also a remarkably shrewd business man. The way he introduced his engine and the manner he advertised are proof of that. He had a keen eye for the things going on in the boiler room. He knew then, as we know now, that when a boiler is forced by unskilled hands, much fuel is wasted, that when a boiler is fired moderately the chances for obtaining drier and consequently less costly steam are far better; therefore he knew that when his engine would be hitched to a battery of overworked boilers those boilers would be greatly relieved and a great saving effected right there in the boiler room.

It is a recorded fact that Corliss believed in ample boiler capacity, believed in "lots of boiler capacity." Boilers furnishing steam to his engines generally had a snap. In those plants installed and guaranteed by Corliss only from one-half to one-third as much steam per square foot of heating surface was generated as in boilers of other plants. He also believed in superheated steam, and all boilers furnished by him were arranged for that purpose. Another condition that existed in those days when Corliss made his bewildering guarantees was that the old engines were too small to handle the load economically, a condition naturally in favor of the new Corliss engine replacing such overloaded units. From this consideration we see that the enormous saving guaranteed and fulfilled by Corliss was not altogether due to the Corliss engine alone, but that a good portion of it must be credited to the changes in the boiler room and to the old engines being overloaded.

Corliss not only made unusual guarantees as to economy but also as to perfect regulation of speed, which merit was of almost as much value to a cotton mill as the saving of fuel. The spindles of a spinning machine revolve with great rapidity, and a variation of speed at the engine will be many times multiplied by the time the motion reaches the fast-running spindle. If the spindle is driven faster than intended, bad work is the result, if it is driven too slow, diminished production is the consequence. The old-fashioned engines were not very satisfactory in governing. The Corliss engine was superior, and Corliss was not slow in guaranteeing it, and he saw to it that his engine rapidly became the standard mill engine. The first engines built by Corliss were of the walking-beam type, but he soon devoted himself to the development of the horizontal type and achieved a wonderful success. He also built a number of pumping engines; the first one was for the City of Providence, R. I. This machine had five horizontal steam cylinders and five horizontal double-acting pumps, evenly spaced around one central vertical shaft. There was no dead-center, no flywheel and no limit to the slow speed which the pump could run. It could run as slow as one revolution in five minutes. In 1857 Corliss built his first cross-compound engine with steam-jacketed cylinders.

In 1870 the Corliss patents became public property, and a number of firms throughout the land began to build Corliss engines. A few shops had been licensed by Corliss, but comparatively few engines were built outside of his works. He charged a license fee not only to outside builders, but also to the firm in which he was a partner. The fee was a dollar and a half per square inch piston area of cylinders over 24 in. diameter, and two dollars per square inch area for cylinders under 24 in. To save the 50c. on each square inch, the first cylinders had large diameters and short strokes, but after the expiration of the patents a marked increase in the length of the stroke with a corresponding decrease in bore is noted.

Fig. 16 is a line drawing of the Centennial Engine of 1876, and Figs. 17, 18, 19 and 20 are sectional details. This is no doubt the most famous engine ever built and was considered when new the most magnificent piece of work in the art of steam engineering. It was enthusiastically praised by all who saw it, and the European engineers credited it an unsurpassed masterpiece of human possibility and the most excellent representative of American steam engineering. The engineering press has referred to this engine times innumerable. I shall, therefore, make mention of only such parts as will be of general interest.

The "Centennial" was a vertical twin engine of the walking-beam type. Each side could develop about 700 hp., at 36 r.p.m., but in Philadelphia it was not called upon to do more than 400 hp. altogether, and it was operated with a steam pressure of from 15 to 22 lb. per sq. in., although it was intended to use 45 lb. The whole engine weighed 607 tons, and it required a train of 35 cars to ship it. The walking beams, of elegant design, had the form of wings, were 27 ft. long and 9 ft. high in the center, and weighed 11 tons each. The flywheel was a gear-wheel, the largest ever made, almost 30 ft. in diameter. It had 216 teeth and weighed 56 tons. The connecting-rods were 25 ft. long, 10 in. thick in the center, and were forged out of 9500 old horseshoes. The cranks were made of solid bronze highly polished and weighed 5 tons each. The cylinders were 40 in. diameter and 10 ft. stroke, steam jacketed. The valves were in the heads and clearance space was reduced to a minimum. The valves were 12 in. diameter and 52 in. long, cored hollow and operated by T-head valve stems. The ends of the valves were cylindrical for a short distance to serve as guides. Port area was $\frac{1}{11}$ of the piston area for the steam valves and twice that amount for the exhaust valves. Each half of the engine had its own condenser and air pump, of the vertical type, 36 in. diameter and 24 in. stroke, operated from the walking beams. The packing was made of wood, as shown in Fig. 20, pieces being joined together in a peculiar manner to break the joints.

I had the good fortune to see this engine in operation one whole day in the Pullman works. It stood in a room 84 ft. square by 66 ft. high kept like a palace. The engine generally delivered 1400 or 1500 hp., but one time it was called upon to deliver 2500 hp. One man's time was continually occupied in keeping the engine oiled. To refill the oil cups on the four extreme pins of the walking beams, it was necessary to shut the engine down every six hours. The engineer stopped the engine at a certain position and the oiler refilled two cups, then he turned the engine half a turn, and the other two cups were filled. In the fall of 1910 this famous engine, after a continuous service of over 30 years, was shut down for the last time and forever.

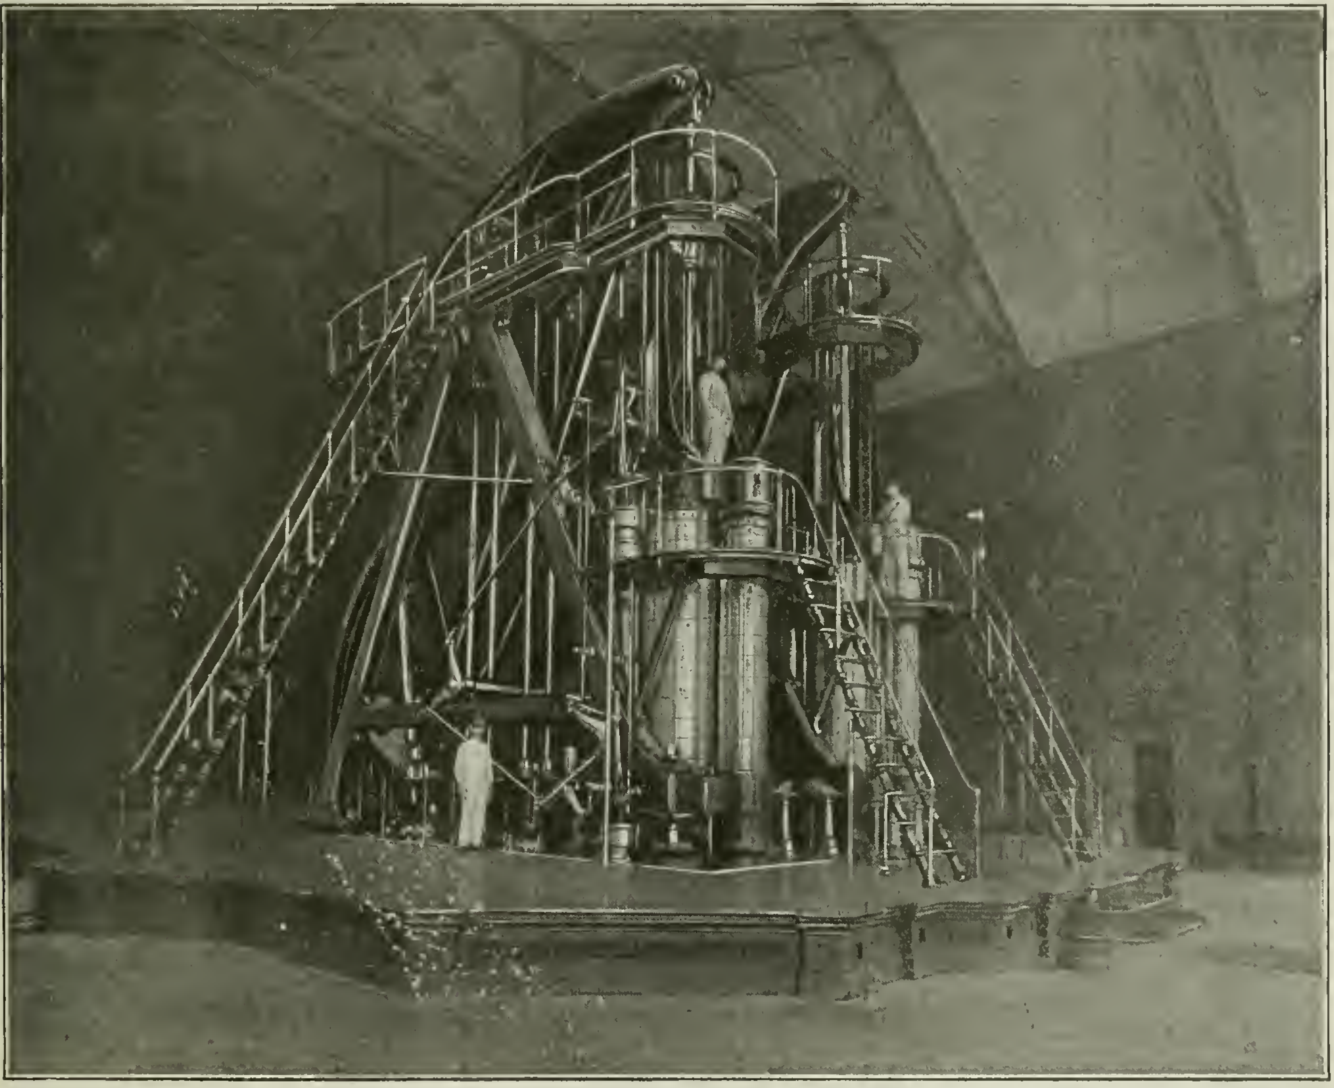

FIG. 21 THE CENTENNIAL ENGINE AT THE PULLMAN WORKS

Zone System for the Distribution of Bituminous Coal

By order of the Fuel Administration, the distribution of bituminous coal for the year beginning April 1, 1918, will be controlled by a zone system, which is intended to reduce the burden on the railroads, facilitate shipment of coal, and keep all the mines working at full capacity.

THE factor that loomed largest in the fuel crisis of last winter was the lack of adequate transportation facilities. Under the plan of distribution then followed, a consumer in any part of the country was free to order his coal supply from any producing district, regardless of the length of haul involved. As a consequence, it often happened that cars and locomotives were engaged in delivering coal to distant regions that could have been served far more quickly from fields near by.

Obviously, this complete freedom of choice as to the source of coal used led to cross-hauling in addition to the utilization of railroad equipment in unnecessarily long hauls, the result being a great waste of transportation power. To prevent this needless waste and make possible an increased production to meet the war demands, the United States Fuel Administration, in conjunction with the Director General of Railroads, has announced a zone system for the control of bituminous-coal distribution for the year beginning Apr. 1, 1918.

The zone system was adopted only after prolonged conferences with coal producers, jobbers and consumers, as well as with the traffic and operating officials of the railroads. Briefly explained, it divides the country into a number of zones, each of which must obtain its coal supply from mines that are relatively near, thus preventing abnormal and wasteful transportation movements, insuring more nearly equal distribution of cars to the mines and more steady employment of mine labor.

Of course, so radical a change in the methods of conducting the coal business will cause some inconvenience to producers and consumers, and will involve additional expense in some cases. For example, the producers of Pocahontas coal may no longer ship their output to Chicago and Western points by rail; as a result, they must find new markets in the East. Those plants in and around Chicago that have been burning West Virginia coal will be compelled to substitute Illinois coal, which can be obtained with less than half as long a haul. As the two fuels are of very different characters, changes in the boiler settings and methods of firing will have to be made, which will entail expense.

It is the hope of the Fuel Administration, however, that the consumer and the producer will bear these unavoidable inconveniences in the realization that the readjustment of the distribution of coal is for the welfare of the nation. In other words, they are appealed to on the grounds of patriotism.

There are exceptions to the conditions imposed by the zone system. Certain industries require coals of particular quality or characteristics, as, for example, by-product, gas, blacksmith and metallurgical coals. If a consumer needs coal of one of these kinds and is unable to obtain it from the producing districts that are permitted to ship into the zone in which he is located, permits will be issued to allow the special-purpose fuel to be brought in from other districts.

The zone system does not affect the following bituminous coal:

1. Coal for railroad fuel, for which special arrangements will be made by the Fuel Administrator and the Director General of Railroads.
2. Coal for movement on inland waterways, which is in no way restricted by the system.
3. Coal delivered to Canada, which is subject to regulations of the Fuel Administrator.

To enable the consumer of bituminous coal to determine the districts from which he may obtain his fuel and to show the producer the zones in which he may sell his output, the map has been prepared.

It will be seen that the entire territory of the United States has been divided into a large number of irregular zones or sections, colored differently so that they may readily be distinguished one from another, and each marked with a key number. Each of these separately numbered zones has certain definite boundary lines and is restricted to the use of coals from certain districts. The Key to Consuming Zones gives a complete list of all the zones shown on the map, states the districts from which they may obtain coal, and defines the boundaries of each zone.

If a consumer wishes to find out what coals are available for his use, he locates on the map the zone in which he lives and notes its number. Then, in the Key to Consuming Zones, under that zone number, he will find the list of producing districts from which he can obtain coal. In case there is any doubt as to the number of the zone in which he lives, reference to the boundaries given in the key will at once decide the point. Following this key is a list of the meanings of the abbreviations and terms used in the key.

The Key to Producing Districts is intended to show the producer the several zones in which he may market his product. He knows the district in which his mine is located, and on referring to this key he finds the numbers of the zones, as shown on the map, into which the output from his mine may be sent.

A wall map of large size, showing the same zoning in fuller detail, may be obtained from the Coal Zone Map Co., Glen Echo, Md.

KEY TO CONSUMING ZONES

ZONE NO. 1

RESTRICTED TO FOLLOWING COALS—North Dakota, South Dakota, docks.

BOUNDARIES—Northern and Western: Lake Superior and Canada; North Dakota state line and South Dakota state line to Ortonville, Minn. **Southern and Eastern:** From Ortonville via C. M. & St. P. Ry. through Granite Falls and Benton Junction to Minneapolis, thence via M. St. P. & S. S. M. Ry. through Chippewa Falls and Abbotsford to Amherst Junction, thence via G. B & W. R. R. to Kewaunee, Wis.; western banks of Lakes Michigan and Huron.

ZONE NO. 2

RESTRICTED TO FOLLOWING COALS—Illinois (summer only), docks, North Dakota, South Dakota, Iowa (to points in Iowa only).

BOUNDARIES—Northern: From Kewaunee, Wis., via G. B. & W. R. R. to Amherst Junction, thence via M. St. P. & S. S. M. Ry. through Abbotsford and Chippewa Falls, Wis., to Minneapolis, Minn., thence via C. M. & St. P. Ry. through Benton Junction and Ortonville, Minn., to the Minnesota-South Dakota state line. **Western:** Minnesota-South Dakota state line. **Southern:** Commencing at South Dakota-Minnesota-Iowa state line east to the C. R. I. & P. Ry. line running through Gordonsville, Minn., and Northwood, Iowa, thence south via that line to Mason City, Iowa, thence east via C. M. & St. P. Ry. through McGregor, Iowa, Madison and Watertown to Milwaukee, Wis. **Eastern:** Lake Michigan from Kewaunee to Milwaukee, Wis.

ZONE NO. 3

RESTRICTED TO FOLLOWING COALS—Illinois, Kentucky (Western), Indiana. docks.

BOUNDARIES—Northern and Western: From Milwaukee, Wis., via C. M. & St. P. Ry. to Waukesha, thence via M. St. P. & S. S. M. Ry. to Illinois-Wisconsin state line. **Eastern and Southern:** From Milwaukee, Wis., via Lake Michigan (west bank) to Illinois-Wisconsin state line, thence via that line to M. St. P. & S. S. M. Ry.

ZONE NO. 4

RESTRICTED TO FOLLOWING COALS—Illinois, Kentucky (Western), docks.

BOUNDARIES—Northern: Via C. M. & St. P. Ry. from Milwaukee, Wis., through Watertown to Madison, Wis. **Southern:** Via C. M. & St. P. Ry. from Milwaukee, Wis., through Milton Junction to Madison, Wis.

ZONE NO. 4A

RESTRICTED TO FOLLOWING COALS—Illinois, docks.

BOUNDARIES—Northern and Western: From Milwaukee, Wis., via C. M. & St. P. Ry. through Milton Junction to Madison, Wis., thence via I. C. R. R. to Dixon, Ill. **Eastern and Southern:** From Milwaukee, Wis., via C. M. & St. P. Ry. through Elkhorn to Beloit, Wis., thence via C. & N. W. Ry. through Belvidere and Sycamore to Dixon, Ill.

ZONE NO. 5

RESTRICTED TO FOLLOWING COALS—Iowa, Kansas, Illinois, Missouri, Oklahoma, Arkansas.

BOUNDARIES—Northern and Eastern: From Sioux City, Iowa, via C. M. & St. P. Ry. through Rock Valley and Spencer to Nora Junction, thence via C. R. I. & P. Ry. to Cedar Rapids, thence via C. M. & St. P. Ry. through Sigourney to Ottumwa, thence via C. R. I. & P. Ry. to Keokuk, Iowa, thence via Missisippi River to Missouri-Arkansas state line. **Western and Southern:** From Sioux City, Iowa, via C. M. & St. P. Ry. through Manilla and Adel to Des Moines, Iowa, thence via C. B. & Q. R. R. to Albia, thence via W. Ry. to Moravia, Iowa, thence via C. M. & St. P. Ry. to Chillicothe, Mo., thence via W. Ry. to Moberly, thence via M. K. & T. Ry. through New Franklin to North Jefferson City, thence via western boundary of Cole, Miller and Pulaski Counties to St. L. S. F. Ry., thence via St. L S. F. Ry. through Springfield and Neosho to Missouri-Oklahoma state line, thence south to Arkansas-Missouri-Oklahoma state line, thence east via Arkansas-Missouri state line to the Mississippi River.

ZONE NO. 6

RESTRICTED TO FOLLOWING COALS—Illinois, Kentucky (Western).

BOUNDARIES—Northern and Western: —From Arthur, Ill., via P. C. C. & St. L. R. R. to Decatur, Ill., thence via I. C. R. R. through Centralia to Cairo, Ill., thence via Mississippi River to Memphis, Tenn. **Eastern and Southern:** From Arthur, Ill., via C. & E. I. R. R. through Marion to Joppa, Ill., thence via Ohio River to Cairo, Ill., and thence via I. C. R. R through Clinton and Fulton, Ky., and Dyersburg, Tenn., to Memphis, Tenn.

ZONE NO. 6A

RESTRICTED TO FOLLOWING COALS—Illinois, Kentucky (Western), docks.

BOUNDARIES—Northern: From Madison, Wis., to Woodman, Wis., via C. M. & St. P. Ry. **Southern:** From Madison, Wis., to Woodman, Wis., via C. & N. W. Ry.

ZONE NO. 7

RESTRICTED TO FOLLOWING COALS—Illinois, Iowa (to points in Iowa only).

BOUNDARIES—Northern and Eastern: From Nora Junction, Iowa, via C. M. & St. P. Ry. to Woodman, Wis., thence via C. & N. W. Ry. to Madison, Wis., thence via I. C. R. R. to Freeport, Ill., thence via I. C. R. R. to Dixon, Ill., thence via C. & N. W. Ry. through Nelson to Peoria, thence via P. C. C. & St. L. R. R. to Decatur, thence via I. C. R. R. through Centralia to Cairo, Ill. **Southwestern:** From Nora Junction, Iowa, via C. R. I. & P. Ry. to Cedar Rapids, thence via C. M. & St. P. Ry. to Ottumwa, thence via C. R. I. & P. Ry. to Keokuk, Iowa, thence east of the Mississippi River to Cairo, Ill.

ZONE NO. 8

RESTRICTED TO FOLLOWING COALS—Illinois, Indiana.

BOUNDARIES—Northern and Eastern: From Dixon, Ill., via I. C. R. R. to Decatur, Ill. **Western and Southern:** From Dixon, Ill., via C. & N. W. Ry. through Nelson to Peoria, Ill., thence via P. C. C. & St. L. R. R. to Decatur, Ill.

ZONE NO. 9

RESTRICTED TO FOLLOWING COALS—Illinois, Indiana, Kentucky (Western).

BOUNDARIES—Northern and Western: From Waukesha, Wis., via C. M. & St. P. Ry. to Beloit, Wis., thence via C. & N. W. Ry. through Belvidere, Sycamore, DeKalb, to Dixon, Ill., thence via I. C. R. R. to Decatur, Ill., thence via P. C. C. & St. L. R. R. to Arthur, thence via C. & E. I. R. R. through Mt. Vernon to Joppa, Ill. **Eastern and Southern:** From Waukesha, Wis., via M. St. P. & S. S. M. Ry. to Wisconsin-Illinois state line, thence via this line to Lake Michigan, thence via Lake Michigan to Michigan City, Ind., thence via C. I. & L. Ry. to San Pierre, thence via N. Y. C. R.R. to Wheatfield, thence via C. & E. I. R. R through Brazil and Otter Creek Junction through Vincennes to Evansville. Ind., thence both sides of the Ohio River, Evansville, Ind., to Joppa, Ill.

ZONE NO. 10

RESTRICTED TO FOLLOWING COALS—Indiana, Illinois (Danville district on Wabash Ry. only). Kentucky (Western, to Jeffersonville and New Albany only).

BOUNDARIES—Northern and Western: From San Pierre, Ind., via N. Y. C. R.R. to Wheatfield, thence via C. & E I. R.R. through Brazil, Otter Creek Junction and Vincennes to Evansville, Ind. **Eastern and Southern:** From San Pierre, Ind., via C. I. & L. Ry. to New Albany, Ind., thence along northern bank of Ohio River to Evansville, Ind.

ZONE NO. 11

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R.R.), Tennessee (M. R.R.), West Virginia (Southern), Illinois, Indiana, Kentucky (Eastern and Western).

BOUNDARIES—Southeastern: From San Pierre, Ind., via N. Y. C. R.R north to South Bend, Ind., thence via M. C. R.R. to Michigan-Indiana state line. **Western and Northern:** From San Pierre, Ind., north to Michigan City, thence along Lake Michigan and Indiana-Michigan state line to M. C. R. R. from South Bend, Ind., to Niles, Mich.

ZONE NO. 12

RESTRICTED TO FOLLOWING COALS—Indiana, Illinois (Danville district on Wabash Ry. only).

BOUNDARIES — Northeastern — From Monon, Ind., via C. I. & L. Ry. to Indianapolis, Ind., thence via C. C. C. & St. L. Ry. through Greensburg to North Vernon, Ind., thence via P. C. C. & St. L. R.R. to Madison, Ind. **Southwestern:** From Monon, Ind., via C. I. & L Ry. to Louisville, Ky., thence via Ohio River to Madison, Ind.

ZONE NO. 13

RESTRICTED TO FOLLOWING COALS—Kentucky (Western).

BOUNDARIES—Northern and Eastern: From Cairo, Ill., along Ohio River (north bank) to Louisville, Ky., thence south via L. & N. R.R. from Louisville through Bowling Green, Ky., including Glasgow and Scottsville branches, to Kentucky-Tennessee state line. **Western and Southern:** From Cairo, Ill., via I. C. R.R. through Fulton, Ky., to Kentucky-Tennessee state line, thence east via state line to L. & N. R.R. running from Franklin, Ky., to Mitchellville, Tenn.

ZONE NO. 14

RESTRICTED TO FOLLOWING COALS—Indiana, Kentucky (Eastern), West Virginia (Northern and Southern), Virginia (L. & N.), Tennessee (M. R.R.), Michigan, Ohio (on G. R. & I. Ry. only).

BOUNDARIES—Northern and Western: From Mackinaw City, east bank of Lake Michigan, to Benton Harbor, Mich., thence via C. C. C. & St. L. Ry. to Niles, thence via M. C. R.R. to Michigan-Indiana state line. **Eastern and Southern:** From Mackinaw City via G. R. & I. Ry. and branches to Michigan-Indiana state line, thence west via state line to M. C. R.R. running from Niles to South Bend, Ind

ZONE NO. 15

RESTRICTED TO FOLLOWING COALS—Illinois, Indiana, Kentucky (Eastern and Western), West Virginia (Northern and Southern), Virginia (L. & N.), Tennessee (M. R.R.), Michigan.

BOUNDARIES—Northern and Western: From Benton Harbor, Mich., via Lake Michigan to Indiana-Michigan state line. **Eastern and Southern:** From Benton Harbor, Mich, via C. C. C. & St. L. Ry. to Niles, thence via M. C. R.R. to Indiana-Michigan state line, thence west via state line to Lake Michigan.

ZONE NO. 16

RESTRICTED TO FOLLOWING COALS—Indiana, Illinois (Danville district on Wabash Ry. only), Kentucky (Eastern), West Virginia (Southern).

BOUNDARIES—Northern: Michigan-Indiana state line from G. R. & I. Ry. west to M. C. R. R. running from Niles, Mich. to South Bend, Ind. **Western:** Via N. Y. C. R. R. South Bend to San Pierre, thence via C. I. & L. Ry. through Monon to Indianapolis, thence via C. C. C. & St. L. Ry., Indianapolis to Greensburg, Ind. **Eastern:** G. R. & I. Ry. from Michigan state line south to Richmond, Ind., thence via P. C. C. & St. L. R. R. to Greensburg, Ind.

ZONE NO. 17

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R.R.). Kentucky (Eastern), Tennessee (M. R.R.), West Virginia (Southern).

BOUNDARIES—From Cincinnati north via P. C. C. & St. L. Ry. to Richmond, Ind., thence west to Rushville, Ind., thence south via C. C. C. & St. L. R.R. through Greensburg, thence east to Cincinnati, O.

ZONE NO. 18

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R.R.), Kentucky (Southern), Tennessee (M. R.R.).

BOUNDARIES—Northern and Western: Cincinnati, Ohio, via C. C. C. & St. L. Ry. through Greensburg, to North Vernon, Ind., thence via P. C. C. & St. L. R.R. to Madison, Ind. **Eastern and Southern:** North bank Ohio River, Cincinnati, Ohio, to Madison, Ind

ZONE NO. 19

RESTRICTED TO FOLLOWING COALS

—Kentucky (Eastern). Tennessee (M. R.R.), West Virginia (Southern, also Eastern, to points on C. & O. Ry. from Catlettsburg, Ky., to Cincinnati, Ohio).

BOUNDARIES—Northern and Eastern. From Louisville, Ky., via Ohio River and Big Sandy River to Kentucky-Virginia-West Virginia state line **Western and Southern:** From Louisville, Ky., to Lebanon Junction to Bowling Green, Ky., to Mitchellville, Tenn., including Glasgow and Scottsville (Kentucky) branches, thence via Kentucky-Tennessee state line and Kentucky-Virginia state line via Tug River to Big Sandy River.

ZONE NO. 20

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R. R.). Kentucky, (Eastern), Tennessee (M. R.R.), West Virginia (Northern and Southern). Indiana. Illinois (Danville district on Wabash Ry. to points in Indiana only), Ohio, Michigan.

BOUNDARIES—Southern and Eastern: From Richmond, Ind, east via P. C. C. & St. L. R. R. to Ohio state line, thence north via state line to Michigan state line. thence via N. Y. C. R. R. to Jackson, Mich., thence via M. C. R.R. to Lansing, thence via P. M. Ry. through Ionia to Howard City, Mich. **Western:** From Howard City, Mich., via G. R. & I. Ry. through Fort Wayne to Richmond, Ind.

ZONE NO. 21

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R.R.), Kentucky (Eastern), Tennessee (M. R.R.), West Virginia (Northern and Southern), Ohio, Michigan

BOUNDARIES—Northern and Eastern: From Mackinaw City, Mich., along the eastern boundary of Michigan (lower peninsula) and Ohio to Toledo, Ohio, thence via C. C. C. & St. L. Ry. through Bellefontaine to Dayton, Ohio **Western and Southern:** From Mackinaw City, Mich., via G. R. & I. Ry to Howard City, thence via P. M. Ry. through Ionia to Lansing, Mich., thence via M. C. R.R. to Jackson, thence via N. Y. C. R.R. to Indiana-Michigan-Ohio state line, thence south along state line and P. C. C. & St. L. R. R running from Richmond Ind., to Dayton, Ohio.

ZONE NO. 22

RESTRICTED TO FOLLOWING COALS—Virginia (L. & N. R.R.), Kentucky, (Eastern), Tennessee (M. R.R.), West Virginia (Southern), Ohio.

BOUNDARIES—From Cincinnati, Ohio, north via C. C. C. & St. L. Ry. to Dayton. Ohio, thence via P. C. C. & St. L. R.R. west to Richmond, Ind., thence southeast via P. C. C. & St. L. R.R. to Cincinnati, Ohio.

ZONE NO. 23

RESTRICTED TO FOLLOWING COALS—Kentucky (Northeastern). West Virginia (Northern and Southern, also Eastern, along main lines of C. & O. Ry. and N. & W. Ry. to Columbus and Cincinnati, Ohio) Ohio.

BOUNDARIES—Northern and Eastern: From Toledo, Ohio, via south bank of Lake Erie to Sandusky, Ohio, thence via P. C. C. & St. L. R.R. through Columbus, thence via N. & W. Ry. through Circleville to Chillicothe. **Western and Southern:** From Toledo, Ohio, via C. C. C. & St. L. Ry. through Springfield to Dayton, Ohio, thence via B. & O. R. R. through Washington C. H. to Chillicothe, Ohio.

ZONE NO. 24

RESTRICTED TO FOLLOWING COALS—Kentucky (Northeastern), West Virginia (Southern, also Eastern, along main lines of C. & O. Ry. and N. & W. Ry. to Columbus and Cincinnati, Ohio), Ohio.

BOUNDARIES—Northern and Eastern: From Dayton, Ohio, via B. & O. R.R. through Washington C. H. to Chillicothe, thence via N. & W. Ry. to Waverly, thence via C. & O. Northern Ry. to Portsmouth. **Western and Southern:** From Dayton, Ohio, via C. C. C. & St. L. Ry. to Cincinnati, Ohio, thence via north bank of Ohio River to Porstmouth, Ohio.

ZONE NO. 25

RESTRICTED TO FOLLOWING COALS—West Virginia (Northern, also Eastern, along main lines of C. & O. Ry. and N. & W. Ry. to Columbus and Cincinnati, Ohio), Ohio.

BOUNDARIES—Northern and Eastern: From Bucyrus, Ohio, via T. & O. C. Ry. to Thurston, Ohio, thence via Z. & W. Ry. through Fultonham to Zanesville, thence via Z. & W. Ry., K. & M. Ry. to Athens. **Western and Southern:** From Bucyrus, Ohio, via P. C. C. & St. L. R.R. to Marion, Ohio, thence via H. V. Ry. to Columbus, thence via N. & W. Ry. to Chillicothe, thence via B. & O. Ry. to Athens, Ohio.

ZONE NO. 26

RESTRICTED TO FOLLOWING COALS—Ohio.

BOUNDARIES—Northern and Eastern: From Sandusky, Ohio, via south bank of Lake Erie to Lorain, thence via W. & L. E. Ry. through Wellington to Pittsburgh Junction, thence via P. & W. V. Ry. through Mingo Junction to Ohio River. **Southern and Western:** From Sandusky, Ohio, via P. C. C. & St. L. R.R. to Bucyrus, Ohio, thence via T. & O. C. Ry. to Thurston, thence through Zanesville to Athens, thence via K. & M. Ry. through Athens to Middleport, thence via Ohio River (north bank) to P. & W. V. Ry. opposite Mingo Junction.

ZONE NO. 27

RESTRICTED TO FOLLOWING COALS—Pennsylvania, Ohio.

BOUNDARIES—Northern and Western: Along south bank Lake Erie from Conneaut, Ohio, to Lorain, Ohio, thence via W. & L. E. Ry. through Wellington to Pittsburgh Junction, thence via P. & W. V. Ry. through Mingo Junction to Ohio River. **Eastern and Southern:** From Conneaut, Ohio, via Pennsylvania-Ohio state line to East Liverpool, Ohio, thence via Ohio River to P. & W. V. Ry. at a point opposite Mingo Junction.

ZONE NO. 28

RESTRICTED TO FOLLOWING COALS—No change contemplated in this plan, except that low-volatile coal in the Pocahontas, Tug River and New River districts on the N. & W. R. R. and the C. & O. Ry. and the Virginian Ry., and Clinch Valley districts in Tazewell and eastern Russell Counties along the N. & W. R. R., also high-volatile east of Charleston, W. Va., on C. & O. Ry. and east of Iaeger, W. Va., on N. & W. R. R. will be restricted to the District of Columbia, (except C. & O. Ry.) Virginia, (including tidewater terminals) also points in West Virginia on the direct line of the C. & O. Ry. and N. & W. R. R. east and west bound and Virginia Ry. east bound.

BOUNDARIES—All territory east and northeast of Ohio, Kentucky and Virginia. including New England.

ZONE NO. 29

RESTRICTED TO FOLLOWING COALS—Ohio, West Virginia (Northern, also Eastern, to points on the direct lines of the C. & O. Ry. and N. & W. Ry.).

BOUNDARIES—Northern and Eastern: From Chillicothe, Ohio, via B. & O. R.R. to Athens, thence via K. & M. Ry. to Middleport, thence via Ohio River (north bank) to Ironton, Ohio. **Western and Southern:** From Chillicothe, Ohio, via N. & W. Ry. to Waverly, thence via C. & O. N. Ry. to Portsmouth, thence via Ohio River (north bank) to Ironton, Ohio.

ZONE NO. 30

RESTRICTED TO FOLLOWING COALS—No change.

BOUNDARIES—All territory west of the following state lines: North Dakota, South Dakota, Nebraska, Kansas, Oklahoma and Texas.

ZONE NO. 31

RESTRICTED TO FOLLOWING COALS—North Dakota, Wyoming, Montana and other fields east of the Rocky Mountains, docks.

BOUNDARIES—All territory in North Dakota west of the Missouri River.

ZONE NO. 32

RESTRICTED TO FOLLOWING COALS—North Dakota, South Dakota, Wyoming, Montana, docks.

BOUNDARIES—Northern, Western and Southern: North boundary of North Dakota to Montana, thence south to and via Missouri River to Mobridge, S. D., thence via C. M. & St. P. Ry. through Aberdeen to Bigstone City, S. D. **Eastern:** East boundary of North Dakota, thence via Minnesota-South Dakota state line to Bigstone City, S. D

ZONE NO. 33

RESTRICTED TO FOLLOWING COALS—South Dakota, Wyoming, Montana and other fields east of the Rocky Mountains, North Dakota, docks.

BOUNDARIES—Northern and Eastern: From Montana-North Dakota-South Dakota state line to the Missouri River, thence via Missouri River to South Dakota-Nebraska state line. **Western and Southern:** Western and southern state boundary of South Dakota.

ZONE NO. 34

RESTRICTED TO FOLLOWING COALS—North Dakota, South Dakota, Wyoming, Montana, Illinois (summer), docks.

BOUNDARIES — Southwestern: From Mobridge, S. D., via Missouri River to Sioux City, Ia. **Northern and Eastern:** From Mobridge, S. D., via C. M. & St. P. Ry. through Aberdeen, S. D., to Bigstone City, S. D., thence via Minnesota-South Dakota state line and Iowa-South Dakota state line to Sioux City, Ia.

ZONE NO. 35

RESTRICTED TO FOLLOWING COALS—Iowa, Kansas, Missouri, Arkansas, Oklahoma, Colorado and other fields east of the Rocky Mountains, Wyoming.

BOUNDARIES—Entire state of Nebraska.

ZONE NO. 36

RESTRICTED TO FOLLOWING COALS—Kansas, Missouri, Iowa, Arkansas, Oklahoma, Colorado (Southern).

BOUNDARIES—Entire state of Kansas.

ZONE NO. 37

RESTRICTED TO FOLLOWING COALS—Oklahoma, Missouri, Arkansas, Kansas, Colorado, New Mexico, Texas.

BOUNDARIES—Entire state of Oklahoma.

ZONE NO. 38

RESTRICTED TO FOLLOWING COALS-New Mexico, Colorado, Texas.

BOUNDARIES—All Texas territory west of Pecos River.

ZONE NO. 39

RESTRICTED TO FOLLOWING COALS—Colorado, New Mexico, Arkansas, Oklahoma, Texas.

BOUNDARIES—Northern and Eastern: From New Mexico-Oklahoma-Texas state line east along northern border of Texas to Arkansas-Louisiana-Texas state line, thence south to Logansport, La., thence via H. E. & W T. Ry. to Houston, via G. H. & H. R R. to Galveston, thence Gulf of Mexico to Rio Grande River. **Southwestern:** From New Mexico-Oklahoma-Texas state line to Pecos River, thence via Pecos River to Rio Grande River thence via Rio Grande River to the Gulf of Mexico.

ZONE NO. 40

RESTRICTED TO FOLLOWING COALS—Kentucky (Western), Alabama, Texas.

BOUNDARIES—Northwestern: From Logansport, La, via H E. & W. T. Ry. to Houston, Texas, thence via G. H. & H R. R. to Galveston. **Eastern and Southern:** From Logansport, La., along Louisiana-Texas state line to the Gulf of Mexico.

ZONE NO. 41

RESTRICTED TO FOLLOWING COALS—Arkansas, Illinois (summer), Iowa, Kansas, Missouri, Oklahoma, docks.

BOUNDARIES—Northern and Western: From Minnesota-Iowa state line directly south of Gordonsville, Minn., to Iowa-Minnesota-South Dakota state line, thence directly south along Iowa-South Dakota state line to Rock Valley, Ia. **Eastern and Southern:** From Iowa-Minnesota state line directly south of Gordonsville, Minn., via C. R. I. & P. Ry. to Mason City, Ia., thence via C. M. & St. P. Ry. to Rock Valley, Ia.

ZONE NO. 42

RESTRICTED TO FOLLOWING COALS—Arkansas, Iowa, Kansas, Missouri, Oklahoma.

BOUNDARIES—Northeast: From Sioux City, Ia., via C. M. & St. P. Ry. through Manilla and Adel to Des Moines, thence via C. B. & Q. R. R. through Chariton to Albia, thence via W. Ry. to Moravia, Ia., thence via C. M. & St. P. Ry. through Seymour to Missouri-Iowa state line. **Western and Southern:** From Sioux City, Ia., via Missouri River (east bank) to Iowa-Missouri state line, thence via Missouri state line, north boundary, to C. M. & St. P. Ry. line running south from Seymour, Ia.

ZONE NO. 43

RESTRICTED TO FOLLOWING COALS—Iowa, Arkansas, Kansas, Missouri, Oklahoma.

BOUNDARIES—Northeastern and Southern: Iowa-Missouri state line from Missouri River to C. M. & St. P. Ry. running south from Moravia, Ia., through Chillicothe, Mo., thence via W. Ry. through Huntsville to Moberly, thence via M. K. & T. Ry. through New Franklin to North Jefferson City, thence via western boundary of Cole, Miller and Pulaski Counties, Mo., to St. L. S. F. Ry. thence via St. L. S. F. Ry. through Lebanon, Springfield, to Missouri-Oklahoma state line. **Western:** Western boundary of Missouri.

ZONE NO. 44

RESTRICTED TO FOLLOWING COALS—Arkansas, Illinois, Kansas, Missouri, Oklahoma, Texas.

BOUNDARIES—Northern and Eastern: From Arkansas-Missouri-Oklahoma state line east to Mississippi River, thence via Mississippi River (west bank) to Memphis, Tenn. **Western and Southern:** From Arkansas-Missouri-Oklahoma state line south to C. R. I. & P. Ry. running from Howe, Okla., through Mansfield, Danville and Little Rock, Ark., to Memphis, Tenn.

ZONE NO. 45

RESTRICTED TO FOLLOWING COALS—Alabama, Arkansas, Illinois •(only on lines of St. L. S. W. Ry. and St. L. I. M. & S. Ry), Kansas, Missouri, Oklahoma, Kentucky (Western), Texas.

BOUNDARIES—Northern and Eastern: From Arkansas-Oklahoma state line via C. R. I. & P. Ry. running from Howe, Okla., through Mansfield, Danville and Little Rock, Ark., to Memphis, Tenn., thence via Mississippi River (west bank) to Arkansas-Louisiana state line. **Western and Southern:** South along Arkansas-Oklahoma state line from C. R. I. & P. Ry. Howe, Okla., to Mansfield, Ark., to Arkansas-Louisiana-Texas state line, thence east along Arkansas-Louisiana state line to the Mississippi River.

ZONE NO. 46

RESTRICTED TO FOLLOWING COALS—Alabama, Arkansas, Illinois (only on lines of St. L. S. W. Ry. and St. L. I. M. & S. Ry.), Kentucky (Western), Texas.

BOUNDARIES—Northern and Eastern: From Arkansas-Louisiana-Texas state line east to the Mississippi River, thence along Mississippi River (west bank) to the Gulf of Mexico. **Western and Southern:** Louisiana-Texas state line to the Gulf of Mexico, thence to Mississippi River.

ZONE NO. 47

RESTRICTED TO FOLLOWING COALS—Kentucky (Western).

BOUNDARIES—Northern and Eastern: From Kentucky-Tennessee state line south of Fulton, Ky., east to L. & N. R. R. passing south through Mitchellville, Tenn., through Nashville and Columbia to Iron City, Tenn., including Scottsville and Hartsville, Ky., branches. **Western and Southern:** From Kentucky-Tennessee state line south of Fulton, Ky., via I. C. R. R. to Memphis, thence east via N. C. & St. L Ry. to Perry-

ville, thence along Tennessee River (east bank) to Alabama-Mississippi-Tennessee state line, thence via Alabama-Tennessee state line to Iron City, Tenn.

ZONE NO. 48

RESTRICTED TO FOLLOWING COALS—Alabama.

BOUNDARIES—Northern and Eastern: From Memphis, Tenn., via N. C. & St. L. Ry. to Perryville, thence via Tennessee River (west bank) to Alabama-Mississippi-Tennessee state line. **Western and Southern:** From Memphis to Arkansas-Mississippi-Tennessee state line, thence east along Mississippi-Tennessee state line to the Tennessee River.

ZONE NO. 49

RESTRICTED TO FOLLOWING COALS—Alabama, Kentucky (Western).

BOUNDARIES—Northern and Eastern: Tennessee-Mississippi state line and Alabama-Mississippi state line. **Western and Southern:** East bank Mississippi River to the Gulf of Mexico.

ZONE NO. 50

RESTRICTED TO FOLLOWING COALS—Kentucky (Southern), Virginia (all Black Mountain and Stonega districts in Lee, Dickenson, Wise, and western Russell Counties of Virginia), Kentucky (Western), Tennessee, Georgia.

BOUNDARIES—Northeastern: From Columbia, Tenn., via L. & N. R. R. to Baugh, Tenn. **Western and Southern:** From Columbia, Tenn., via L. & N. R. R. through Lawrenceburg to Iron City, thence east via Alabama-Tennessee state line to Baugh, Tenn.

ZONE NO. 51

RESTRICTED TO FOLLOWING COALS—Alabama, Kentucky (Southern), Virginia (all Black Mountain and Stonega districts in Lee, Dickenson, Wise, and western Russell Counties of Virginia), Tennessee, Georgia.

BOUNDARIES — Northern: Tennessee-Alabama state line. **Southwestern and Eastern:** Tennessee River.

ZONE NO. 52

RESTRICTED TO FOLLOWING COALS—Alabama.

BOUNDARIES—Northern and Eastern: Tennessee River to Alabama-Georgia state line, thence south along state line to Apalachicola River, thence via said river to the Gulf of Mexico. **Western and Southern:** Alabama-Mississippi state line to the Gulf of Mexico.

ZONE NO. 53

RESTRICTED TO FOLLOWING COALS—Kentucky (Southern, also Western, to points on N. C. & St. L. and T. C. R. R. Nashville to Old Hickory and Hermitage, Tenn. inclusive), Virginia (all Black Mountain and Stonega districts in Lee, Dickenson, Wise, and western Russell Counties of Virginia, also Clinch Valley district in eastern Russell and Tazewell Counties), West Virginia (Eastern, also Southern, on C. & O. Ry. east of Charleston and N. & W. Ry. east of Iaeger, W. Va.), Georgia, Tennessee.

BOUNDARIES—Northern and Eastern: From Mitchellville, Tenn., east along Tennssee-Kentucky state line to Virginia state line, thence via L. & N. R. R. to Norton, thence via N. & W. R. R. through Roanoke. Petersburg (and branches of N. & W. R. R. at Petersburg) to Norfolk, thence south to Virginia-Carolina state line. **Western and Southern:** From Mitchellville, Tenn., via L. & N. R. R. through Nashville and Columbia to Baugh, Tenn., including Scottsville, Ky., branch, thence along Alabama-Tennessee-Georgia state line, thence via North Carolina-Tennessee state line, thence via North Carolina-Virginia state line to the Atlantic Ocean.

ZONE NO. 54

RESTRICTED TO FOLLOWING COALS—Kentucky (Southern), Tennessee, Virginia (all Black Mountain and Stonega districts in Lee, Dickenson, Wise, and western Russell Counties of Virginia), Alabama, Georgia.

BOUNDARIES—State of Georgia and all of Florida east of Apalachicola River.

ZONE NO. 55

RESTRICTED TO FOLLOWING COALS—Kentucky (Southern), Virginia (all Black Mountain and Stonega districts in Lee, Dickenson, Wise, and western Russell Counties of Virginia), Tennessee, Georgia, West Virginia (Eastern).

BOUNDARIES—Northern and Eastern: From Georgia-North Carolina-South Carolina state line to the line of the Sou. Ry. running south from Charlotte, N. C., through Chester to Columbia, S. C., thence via S. A. L. Ry. to Denmark, thence via Sou. Ry. to Charleston, S. C. **Western and Southern:** South Carolina-Georgia state line to the Atlantic Ocean.

ZONE NO. 56

RESTRICTED TO FOLLOWING COALS—Kentucky (Southern), Tennessee, Virginia (all Black Mountain and Stonega Districts in Lee Dickenson, Wise and western Russell Counties of Virginia, and Clinch Valley districts in Tazewell and eastern Russell Counties along the N. & W .Ry), West Virginia (Eastern, on C. & O. Ry. and N. & W. Ry. and Virginian Ry.).

BOUNDARIES—All of North Carolina, and that portion of South Carolina on and east of the line of the Sou. Ry. Charlotte, N. C., through Chester to Columbia, thence via S. A. L. Ry. to Denmark, thence via Sou. Ry. to Charleston, S. C.

ZONE NO. 57

RESTRICTED TO FOLLOWING COALS—No change contemplated. Coal to be supplied generally from low-volatile fields.

BOUNDARIES—That portion of Virginia on and north of the N. & W. R.R. Graham, Va., to Norfolk, Va., including branches at Petersburg.

The Government and The Water Powers

An Interview with

Hon. Franklin K. Lane

SECRETARY OF THE INTERIOR

IN THE hearings before the Special House Committee on the Administration's Water-Power Bill, Chairman Sims asked a number of questions which involved the right or the probable disposition of the Federal Government to take over and operate the properties upon the expiration of the license. At that time, under the measure before the committee, the Government would have its choice of three courses:

To take the property;

To transfer the privilege to another licensee;

To renew the license to the original holder.

Suppose, as likely to be the case, that there is no other applicant for the privilege; then the Government must either renew the license or take the project over and operate it. If the Government has no use for the power for purely governmental purposes such as making nitrates or munitions or operating possibly government-owned railways, could it make current for sale? Has it the right under the Constitution to go into the business of supplying electricity for light, heat and power, and water for irrigation commercially? If so, is it entitled to do so at a profit or would it have to furnish the current at cost? Would it be possible against powerful opposing influences to get Congress to vote a huge appropriation for the purpose of going into business in competition with an industry the recent growth of which is significant of what it will come to be in fifty years?

Would License Be in Effect a Grant in Perpetuity?

If the Government were found to be unauthorized to take over such a project and operate it commercially or if the objections to doing so were insuperable, would it not be reduced to the necessity of renewing the license to the original holder and that upon his own terms? Would not the license under such circumstances be in effect a grant in perpetuity?

This phase of the question evoked so much interest and discussion among those present at the hearings and others that we sought an expression from Secretary Lane, whose experience in former connections as well as in his present administrative position gives especial weight to any utterance of his upon the subject.

The Secretary expressed the opinion that the license would not, in effect, be a grant in perpetuity, for the reason that the bill provides that a renewal in such case shall be upon such terms and conditions as may be prescribed by the then existing laws, affording Congress ample opportunity to impose such new terms or conditions as the public interest shall then be deemed to require. The Government will not be required to renew the license upon the original holder's "own terms," because if the United States does not take over the properties itself or find another applicant who will take them, the original licensee must accept any condition offered or abandon his property and lose his whole investment.

As to the right of the Government to acquire and operate such a project, Mr. Lane thought there could be no doubt. The Salt River reclamation project, he said, "which I have turned over to the water users for operation," is practically paying its own way out of the power developed under the Roosevelt dam. The Shoshone reclamation project in Wyoming, built by the Department, is furnishing water for irrigation and electricity to towns and industries within a wide radius, as is also the project at Minidoka, Idaho.

Government Right to Sell Water and Electricity

"Has the right of the Government to sell water and electricity ever been questioned?" we asked.

"Never," replied the Secretary. "If it were, how would you justify it? There is probably no inhibition, but it is urged by the opponents of Government activities of this sort that among the powers conferred upon the Federal Government by the constituent states there are none which can be construed to warrant such undertakings.

"I know of no inhibition in the Constitution or elsewhere upon the right of the Federal Government to develop water power and dispose of the product to the public," said the Secretary. "Under the Constitution, the Federal Government has jurisdiction and authority over the navigable waters of the United States, under which authority dams and other works for the improvement of navigation are constantly being constructed. Many of these structures involve the incidental development of water power, and there can be no question, I think, of the right of the Government to utilize this incidental value for the benefit of the public and to secure a return to the Federal Treasury of a part of the expenditures made for such improvements.

Right of Congress to Dispose of Public Lands

"As to the public lands, the Constitution vests in Congress full authority to 'dispose of' the same. The Supreme Court has stated that Congress may deal with these lands precisely as an ordinary individual may deal with his property, and that as the lands are held in trust for the people of the whole country, it is for Congress to determine how they shall be handled. For instance, Congress has a right to establish forest and other reservations for public purposes, or to devote lands to some other national or public purpose. These are rights incident to proprietorship, to say nothing of the power of the United States as a sovereign over the property belonging to it. Furthermore, the so-called general welfare clause of the Constitution has been given a very liberal construction and indicates the intention of the framers of the Constitution to confer very broad powers upon the Federal Government for the public good. The Government was created by the people and is operated for their benefit. If the public interest warrants or requires the development of electrical power and its sale by the Federal Government, the Constitution seems to fully warrant the undertaking.

"But," continued the Secretary, "would not the probable outcome be that the municipality, which would naturally grow up about one of these developments, would acquire it on the expiration of the license? A project too large for a municipality or a drainage or other district could be acquired by the state. There is no doubt of the competency of any state to enter upon such an undertaking, and the competency of a municipality or district is a matter of state legislation. In view of the present tendency of public opinion one can well imagine a general disposition on the part of communities to own their own public utilities by the time these licenses begin to expire."

Public Ownership of Public Utilities

We acknowledged our sympathy with the tendency and the probability of the suggested outcome so far as public utilities were concerned. "But what," we asked, "would happen in the case of a project which served only special industries; big metallurgical works, for example? If a license were granted to a syndicate of paper manufacturers to develop a power for the manufacture of paper, what could the Government do with that on the expiration of the license, and would it have any control of the project in the meantime? Not being a public utility, would it come within the jurisdiction of a public-utility commission or similar body? Could the Federal commission control it? If the commission undertook to recover exorbitant profits by the imposition of a high rental, they would simply pass the charge on to the consumer."

Secretary Lane thought that this would be a very exceptional case. "A community would undoubtedly grow up about such an industry and the water power would supply the needs of that community and so become to an extent a public utility, sufficiently so perhaps to warrant the community in taking it over. Most public utilities furnish power as well as light, and their status as public utilities is not determined by the proportion of their output sold for power or the number of their power customers. As to rate control during the term of the license, the syndicate would have to sell in competition with other manufacturers and the growing sentiment in favor of restricting prices to cost plus a fair profit and legislation against control of production and distribution could be depended upon to prevent an abuse of the privilege or its use for speculative purposes. The time is long past, and wise men see that it is past, when there is a speculative value in these things. The right of the community, of the nation, of the collective body of citizens that we call the people of the United States, their right is superior to any right that you or I may have to speculate upon those things that are primary resources."

"What is your attitude, Mr. Secretary," we asked, "toward the initial development of the powers by the Federal Government?"

"If we had money enough," said Mr. Lane; "if this were not a time of war; if we could think in the terms of money that we are now thinking of; or if four or five years ago Congress had been willing to expend hundreds of millions of dollars in the development of water power as it is forced now to spend billions of dollars for war—then it would be a wise thing to put a large part of the public revenues into such projects where they are found to be needed. I have no doubt in my own mind that such schemes as water-power developments are perfectly practicable from a governmental standpoint, no matter what your sympathies may be respecting Government ownership, as a rule, of large utilities. A thing that is as well standardized as a water-power scheme can be operated successfully by the Government. But I do not think that this is practicable at this time nor probably will it be for many years to come, and it is necessary that there should be real development, and that soon.

"The water powers should be given into the hands of the men capable of developing them under such conditions as will warrant large investment. We cannot save things for men who have no capital, or men who go about things with a spade where a steam shovel is needed. The conditions under which these privileges are granted should guard against extortion during their use and insure the return of the resource to the people at the termination of the license if the people want to take it back by refunding the net investment. The term of the grant should be long enough to afford the promoter or *entrepreneur* an opportunity to make a profit commensurate with his risk and enterprise, and to attract the necessary interest, talent and capital to get some good out of these powers for the present generation and stop our extravagant incursions upon the supply of fuel that is of increasing value for other than power purposes. The bill before Judge Sims' committee is designed to do this and seems to promise to do it better than any measure previously offered."

Our Government wants to spend 19 billion dollars this year, a sum so vast that it cannot be comprehended. From 1791 to Jan. 1, 1917, a period of 126 years, the Government spent only 26 billion, 300 million for all purposes—for wars and in times of peace, for pensions, for the Panama Canal, and for every other expense of the Government. This is only about five billion dollars more than has been appropriated by Congress to be spent in one year to provide for the tremendous demands of the war. This sum cannot be borrowed except from the people. It cannot be raised except by taxation or loans from the current income of the people. We must save and lend our savings to the Government.

What is the Capacity of a Turbine?

In "Power" for Mar. 19 appeared an editorial on the question which forms the title above. There is renewed interest in the subject. In the editorial those interested were invited to express their opinions. Some are given in this article.

THE Power Test Code of the American Society of Mechanical Engineers, page 30, paragraph 23, reads as follows: "The commercial rating of capacity determined on for power-plant apparatus, whether for the purpose of contracts for sale, or otherwise, should be such that a sufficient reserve capacity beyond the rating is available to meet the contingencies of practical operation; such contingencies, for example, as the loss of steam pressure and capacity due to cleaning fires, inferior coal, oversight of the attendants, sudden demand for an unusual output of steam or power, etc."

Needless to say, this paragraph is controversial, and is the subject of serious consideration by the Power Test Committee of the society, which committee is now revising the code.

The Prime Movers Committee of the National Electric Light Association has not expressed itself on this question of turbine capacity. The Association of Edison Companies has not declared what it accepts or agrees is the capacity of a turbine, neither has the American Institute of Electrical Engineers so far as the writer can learn. This much may be said: Most engineers responsible for the selection and operation of large turbines, particularly, agree that if a turbine guaranteed to give a specified capacity at specified conditions of steam pressure, superheat and vacuum gives the specified capacity, the builder has fulfilled his obligations though not one kilowatt more than that capacity can be got, the steam pressure, superheat and vacuum being the same.

The expressions which follow are by men prominent in turbine and power-station development; all are anonymous.

From a user: The writer has closely followed turbine development practically from its start, and was not aware that there was any active question about turbine rating at this time. If, however, this question is active, the American Society of Mechanical Engineers should investigate and report upon the subject.

Another procedure which I would suggest is to submit this matter to the consideration of the Prime Movers Committee of the National Electric Light Association and the Steam Plant Committee of the Association of Edison Illuminating Companies. Both of these bodies are composed of the leading men in the electrical industry, all of whom have given much thought to turbine matters.

In the earlier days of turbine development it was customary to apply two ratings to a machine; namely, normal capacity and maximum capacity. This double rating was objectionable and has been abandoned. Today, turbines are rated on maximum capacity based on steam pressure at the throttle, or in the bowl, superheat and vacuum. These conditions are applied to a steam engine, and there is no uncertainty in the mind of anyone about the performance of the engine. They apply just as well to the turbine. When these conditions are complied with by the purchaser and the guaranteed kilowatt load is developed by the turbine, the purchaser is getting what he purchased, and he has no more grounds for asking that he should get a greater output than he would have to expect a grocer to sell him a pound and a quarter of sugar when he ordered a pound.

The character of the station load has nothing to do with the capacity of the turbine. Load fluctuations vary with different stations, and they vary from hour to hour in any station. The turbine manufacturer does not know and is not concerned about this; that is a matter of engineering on the part of the purchaser. If the latter does not properly do his engineering the turbine manufacturer should not be blamed.

As a matter of fact, I think the thought that inspired the editorial was not the determining of the capacity of a given turbine when steam conditions are fixed, but determining what capacity turbine should be installed to meet load conditions in a given station. This is a matter that cannot be governed by any set of rules, but must be determined for each specific case.

From a designer: It is not surprising that there should be revived the question, "what is the Capacity of a Turbine," notwithstanding all that has been written on the subject. The bald statement of so many kilowatts capacity means nothing without more explanation, and if one desires to state the capacity, more explanation is necessary. This is rightly so, for in accordance with the required service some turbines are designed to have very large and others very small capacities above the point at which their steam consumption is best, all depending upon the load factor. This perhaps has been rendered more aggravating by a tendency on the part of salesman and purchaser alike to say their turbine is as big as they can stretch it. It is not uncommon for a turbine and generator to be called upon to sustain a load 100 per cent. in excess of the average load for a limited time; which gives opportunity for a wide disparity of rating.

The old Corliss engine practice of giving an engine an arbitrary overload capacity of 50 per cent. would seem to have no place today because of the varying load factors that obtain; for example, in large lighting systems on the one hand, where a turbine, if operating at all, is operating close to its point of best steam consumption, a very small percentage capacity above this is needed. On the other hand there are other plants, railroads, for example, where the turbine is called upon to sustain heavy peak loads and swings, sometimes requiring a capacity 100 per cent. in excess of the point of best steam consumption.

It is certainly convenient to specify the rating of the generator at its maximum continuous capacity, and so far as the generator itself is concerned, there need never be confusion. With the turbine the matter is more difficult, and this is made doubly so by its extreme flexibility. A turbine designed to pass a given number of pounds of steam, if designed with proper regard to the volumes of steam, will give the best performance with a flow of this quantity. It requires no particular ingenuity on the part of the designer to find means of passing a much larger quantity of steam through the turbine, permitting much greater loads, with some impaired efficiency.

If your question is prompted by considerations of the safety of the turbine under overload, as seems to be implied, then it may be said that with full specified pressure behind all the nozzles with which the turbine is equipped, or, if bypassing is resorted to with full pressure at these secondary points of admission, no dangerous pressure should obtain in any of the lower stages. In other words, the turbine is defective if it cannot be caused to slow down by an excessive overload without injury to the turbine. This also with allowance for a reasonable increase of pressure beyond that specified and also with a simultaneous loss of vacuum which in itself will cause increase of pressure in certain of the low-pressure stages.

It may be thought desirable by some people to state in a word the capacity of a machine which rather more expresses its monetary value, or its physical dimension for the same reason that many years ago prompted the use of the term "nominal horsepower."

Is not the matter entirely covered and made clear by merely stating the kilowatts capacity at the point of best steam consumption, and in addition the maximum continuous kilowatts capacity; the latter being the extreme load the turbine is warranted to sustain when operating under the specified operating conditions? The former in a measure expresses the size of the machine. To describe the complete unit one should further amplify this by quoting the maximum continuous rating of the generator, which is not necessarily the maximum capacity of the turbine.

From a user: Before the days of large steam turbines the commercial rating of reciprocating engines was established by common practice at about 85 per cent. of their maximum capacity, which gave considerable overload capacity to meet the swings which might demand capacities above the commercial rating.

When turbines entered the field it quite naturally followed that their rating should be calculated on the same basis, and in addition, the turbine designers, lacking in experience and data combined with a desire to produce the required horsepower in their machines, very much underestimated their capacity, and in comparison with the generators turbines were much overpowered and furnished almost unlimited overload capacity. Sometimes the capacities were as high as 100 per cent. above builder's rating. It is not difficult to see that this condition would eventually adjust itself to a more accurate basis for calculating capacities when the experience in operation had demonstrated that turbines were, in comparison with reciprocating engines, much underestimated, with the result that today machines are rated at 7500 kw. which in former years were sold for 5000-kw. machines. The former has led to confusion when referring to turbine capacities, producing a new term, "maximum capacity," to denote the physical limit of output as compared with the old commercial rating.

At present contracts for turbines are drawn with the understanding that with a given steam pressure, superheat and vacuum they will develop their maximum rating. As it is difficult to design a turbine so that it will develop its rated capacity and no more, there is generally a slight reserve capacity above the rated capacity. Should a turbine purchased as a 10,000-kw. machine on test develop 11,000 kw., the purchaser has a 10,000-kw. rated machine with capacity of 11,000-kw.; but it does not follow that all 10,000-kw. machines will carry 11,000 kw. Under the same contract conditions should the turbine develop 10,000 kw. only as its maximum load, the contractor has met his obligations. Should the turbine fail to carry the rated load when the conditions of pressure, temperature and vacuum are not met with, the machine does not in any sense become one of lower capacity.

As all turbine installations should include recording instruments to measure the load, vacuum, pressure and temperature, the question of conditions under which a machine might fail to maintain its speed is easily determined.

The load to be reported to the public service commission from the operating station should be maximum hour, maximum of 15 min. and the maximum swing.

The writer of the first communication mentions that the question of what capacity turbine should be installed to meet load conditions in a given plant may have been the thought which prompted the editorial. While the questions of capacity of a particular turbine and of what capacity turbine or turbines should be installed for given load conditions are separable, they are, of course, closely related, one greatly influencing the other.

This latter question has always been a controversial one; but since the introduction of turbines of large capacity—units of 30,000 and 35,000 kw. are becoming numerous and some of 60,000 kw. are being built—it has become more unsettled. This question, which is that of what reserve capacity to allow, also is one demanding consideration by individuals and the engineering societies.

How Is This for Red Tape?

Considerable has been said about the water-power developments of this country being tied up with governmental red tape, but how about Italy? E. Strachan Morgan, writing in the London *Electrical Review* on, "Electrical Developments in Italy," says:

> There were a short time ago lying in the Ministero delle Finanze 2600 demands for water-power concessions, some of which had been on file for more than 20 years. Even by the provisions of the Villa Bill, drafted with a view to simplifying procedure, every demand goes through twelve stages. It goes to the Prefetto, to the Genio Civile, to the Magistrato Supremo delle Acque in Rome, then back to the Prefetto, to the Deputazione Provinciale, then back to the Genio Civile, which at last orders a survey of the local conditions, then back to the Magistrato Supremo in Rome, then to the Ministero dei Lavori Pubblici, then back to the Magistrato Supremo, then to the Ministero delle Finanze, at whose recommendation the concession may be granted by a Decreto Reale. It does not take much knowledge of bureaucratic procedure to realize what considerable possibilities of delay there are even in this "express" treatment of a demand.

Determining of Load Centers of Circuits*

By TERRELL CROFT

The object of this article is to explain the location of load centers of electric circuits in a way that it can be readily understood. The results given by the methods indicated, are not absolutely accurate, but they are sufficiently so for all practical purposes.
